Details of Rowntree's tumbler-lock.

AA is the plate that encloses the whole mechanism of the lock, and fastens it to the door; **B B** is the bolt, guided in its motion

by sliding under the bridges **CD**; **EE** are pillars which support a plate covering the works; **F** are the circular wards surrounding the center or key-pin; and **a** shows the position of the key, which, in turning round, acts in a notch **t** in the bolt, and propels it; **G**, the tumbler, is a plate situated beneath the bolt, and moving on a center-pin at **d**; it has a catch or **stump e** projecting upwards, which enters the notches **f** or **g** in the bolt, and thereby retains the latter for backward or forward motion, as the case may be; **H** is a spring which presses the tumbler forward. The key **a**, in turning round, acts first against the part **c c** of the tumbler, and raises it so as to remove the stump from the notches; it can then enter the notch **r** in the bolt, and move it.

So far there is no particular security; but Mr. Rowntree sought to obtain it by the following means. There is a piece of metal **h** fixed to the lower side of the tumbler, called the *pin;* when the tumbler is caught in either notch of the bolt, the pin applies itself to a cluster of small wheels **l**, fitted on one center-pin beneath the tumbler; the edges of these wheels stop the pin, and prevent the tumbler from being raised.

But each wheel has a notch cut in its circumference **l**; and it is only when the wheels are so placed that all their notches lie in a right line, that the pin can enter this compound notch and allow the tumbler to rise. The wheels must therefore be all adjusted to position; and this is effected by a number of levers **K** centered on one pin at **k**; at the opposite end each lever has a tooth **m** entering a notch in the wheel belonging to it; so that when any lever is pressed outward, it turns its wheel round.

Now this pressure of the levers is brought about by a spring **n** applied to each; and when so pressed, the levers rest against a pin **o** fixed in the plate. The key is so cut as to determine the extent to which the levers shall act upon the wheels. The key first operates from the curved part ***p p*** of the levers **K**, and raising them, turns all the wheels **l** at once into the proper positions; in turning further round, it then operates on the part **c c** of the tumbler, causing the latter to rise and to release the bolt; and in turning still further round, it (the key) seizes the notch **r** of the bolt, and shoots it.

The key is cut into steps of different lengths, as shown at **vv**; each step operates on its respective lever **K** in a different degree from the others; the notch at **s** acts upon the tumbler, and the plain part **t** moves the bolt.

We now proceed to notice the modern tumbler-lock. This was arranged by Bird, whose patent, bearing date 29th October, 1790, was for a series of four double-acting tumblers, differing in no respect from those patented by Barron, and closely resembling those in use at the present time in the best tumbler-locks. We will describe the modern tumbler-lock more particularly when we have gone through a few historical details on the subject.

Messrs. Mitchell and Lawton obtained a patent bearing date 7th March, 1815, for a lock in which were combined with the bolt and double-acting tumblers, a series of moveable wards and a revolving curtain for closing the key-hole. The action of the wards was peculiar.

On introducing any key or instrument, and passing it round, a number of moveable wards or pieces were thrown out so as to prevent the key from being turned back or withdrawn. It was necessary therefore to pass round the key so as to unlock the lock, and if that were not possible, as in the case of a false key being used, it was held permanently, and could only be released by destroying the lock. When the bolt was once shot, the wards were carried up so as to leave a clear passage for the key. This lock does not appear ever to have come into use, on account of the violence required in case a wrong key should be used either by accident or design.

The detention of a wrong key in this lock appears to have suggested the contrivance of a *detector.* This was first made by Ruxton, whose patent is dated 14th May, 1816. His detectors were of various kinds, the object of each kind being to give information to the owner in case any one of the tumblers should be over-lifted in an attempt to pick the lock, which fact would be discovered on the next application of the true key.

This is precisely the object of the detector in tumbler-locks at the present day, and Buxton accomplished it by somewhat similar means. He also had a contrivance for holding a false key, as in Mitchell and Lawton's lock; and he recommended this form of detector in the following words:

"It is true that in this case the lock will have to be destroyed in order to open the door: the result is frightful; but we think the more terrible the result, the less likely would anyone be to tamper with it."

We now come to Chubb's lock, patented February 3, 1818, which consisted of double-acting tumblers and a peculiar kind of detector. This lock has been made the subject of various patents obtained in the years 1824, 1833, 1846, and 1847. This lock consists of six separate and distinct double-acting tumblers, all of which must be raised to a particular height, neither more nor less, in order that the bolt may pass. It also comprises a *detector,* by which, should any one of the tumblers be lifted too high in an attempt to pick or open the lock by a false key, it would be immediately detected on the next application of the proper key. The tumblers are flat pieces of iron or steel, with the plane of the surface vertical, and pivoted at one end; and the following is the mode in which the key, the tumblers, and the bolt are brought into mutual action.

The bolt shoots in and out of the lock in the usual way. It has a square stud or stump riveted on one surface; and it is to furnish obstructions to the passage of this stud that the tumblers are provided. All the six tumblers are pivoted to one pin at the end, giving to each of them a small leverage, each independent of the others.

There are six springs that press these tumblers downwards, one to each tumbler. There is a longitudinal slot or gating in each tumbler, large enough to receive the stud of the bolt; and unless all the six slots (supposing there to be six tumblers) coincide in height or position, the stud will not have a clear passage for moving laterally.

The slots are purposely made nearer the upper edge in some of the tumblers than in others, all the six being different in this respect; so that if they are all lifted ***equally,*** the slots do not coincide, and the bolt and its stud will not pass. The tumblers must then be raised ***unequally,*** those to be most raised which have the slot nearest to the lower edge. To effect this, the bit of the key is cut into six steps or inequalities, each to act upon one particular tumbler, and each cut or stepped to the exact depth which will suffice for the proper raising of the tumbler.

The key is inserted in the keyhole, and is turned; the six steps raise the six tumblers all to the proper height, to leave a clear passage along the slots; and the extreme end of the key then acts upon the bolt itself, and shoots it. To unlock it again, the same or a duplicate key must be used; for if another key be employed, differing by ever so little from the proper one, some one or more of the tumblers will be lifted either a little too much or not

quite enough.

In either case, the stud of the bolt will catch above or below the slot, instead of having a clear line of movement along the slot itself. After both locking and unlocking, the springs force the tumblers down as far as they can go, burying the stud in the recesses above the slot; so that the tumblers must be raised by the key both for locking and unlocking.

The doctrine of chances has wide play in determining the relative position of the six tumblers. In Mr. Chubb's essay, this part of the subject is treated in the following way: "The number of changes which may be effected on the keys of a three-inch drawer-lock is 1 x 2 x 3 x 4 x 5 x 6 = 720, the number of different combinations which may be made on the six steps of unequal lengths (on a six-tumbler lock), without altering the length of either step. The height of the shortest step is, however, capable of being reduced 20 times; and each time of being reduced, the 720 combinations may be repeated; therefore 720 x 20 = 14,400 changes.

The same process, after reducing the shortest step as much as possible, may be gone through with each of the other five steps; therefore 14,400 x 6 = 86,400, which is the number of changes that can be produced on the six steps. If, however, the seventh step, which throws the bolt, be taken into account, the reduction of it only ten times would give 86,400 x 10 = 864,000, as the number of changes on locks with the keys all of one size (that is, with one key of definite size in all save the lengths of the steps).

Moreover, the drill pins of the locks and the pipes of the keys may be easily made of three different sizes; and the number of changes will then be 864,000 x 3 = 2,592,000, as the whole series of changes which may be gone through with this key. In smaller keys, the steps of which are capable of being reduced only ten times, and the bolt-step only five times, the number of combinations will be 720 x 10) x 6 x 5 x 3 = 648,000. On the other hand, in larger keys, the steps of which can be reduced thirty times, and the bolt-step twenty times, the total number of combinations will be 720 x 30 x 6 X 20 x 3 = 7,776,000.

These enormous numbers have been the cause of much of the wonderment which the six-tumbler locks have excited; and, as we shall see further on, the Bramah lock presents still more of the marvelous in respect to this ringing of the changes.

The construction and action of the Chubb lock may be further illustrated by means of an engraving, **Figure 31**, in which **b** is the bolt of the lock, with a stump riveted to it marked **a**. The six tumblers are shown perspectively, the front or anterior one being marked **t**; they all move on the center-pin **a**, but are nevertheless perfectly distinct and separate to allow being elevated to different heights.

At **d** is shown one end of a divided spring, the divisions being equal to the number of tumblers, one to each, and so bent that each spring may press upon its particular tumbler.

At ***e*** *is* the detector-spring, so placed that a projecting piece in the hindmost tumbler shall be near it; this tumbler having also fixed into it a stud or pin **p**. This being the arrangement, especially in relation to the stump **s** and the tumblers, it follows that all the tumblers must be lifted to exact and regulated heights in order that the stump may pass through the longitudinal slits of the tumblers. Unless it can do so, the bolt cannot be withdrawn. As there are gaps or notches in each tumbler both above and below the proper line of passage.

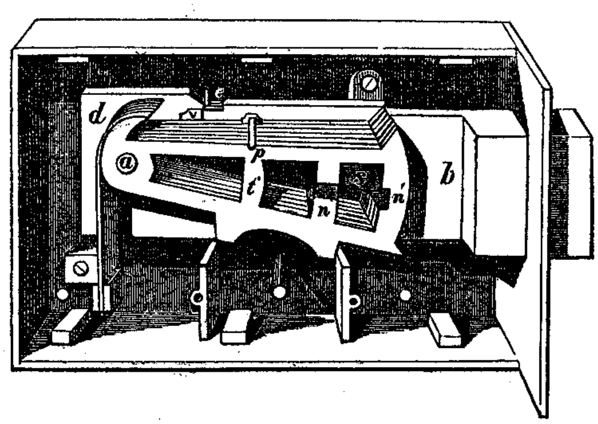

Figure 31 Chubb lock with detector and six tumblers.

As there are no ordinary means of ascertaining when any one tumbler is lifted too high or not high enough, the safety of the lock is greatly increased by this uncertainty; especially when it is considered that this uncertainty is multiplied six-fold by the different modes in which the six tumblers are slotted.

If, through the insertion of a false key, or by any other cause, any one of the tumblers be raised above its proper position, the detector spring **e** will catch the hindmost tumbler, and retain it

so as to prevent the bolt from passing; and thus, upon the next application of the true key, it will be instantly felt that some one of the tumblers has been over-lifted, because the true key will not unlock it.

To relieve the bolt from this temporary imprisonment, the key must be turned the reverse way, as for locking; all the tumblers will thus be brought to their proper position, and allow the stump to enter the notches **n n**, the beveled part of the bolt will then lift up the detector spring, and allow the hindmost tumbler to fall down into its proper place; and all this being effected, the lock may be opened and shut in the ordinary way. The pin **p** is so adjusted that if any one of the tumblers, front, back, or intermediate, be lilted too high, the pin will be lifted with it, and will catch into the detector-spring, thus producing the result just described.

The key is represented in **Figure 32**. It has six steps, besides a terminal step to act upon the bolt. The height of each step, or the distance to which it extends from the pipe of the key, depends of course on the height to which its corresponding tumbler is to be lifted; and it matters not whether the steps of the key are adjusted to the slots of the tumblers, or the slots to the steps, provided the agreement be brought about.

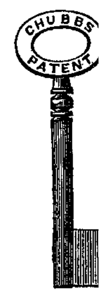

Figure 32 :
Chubb's 1

It is simply a matter of manufacturing convenience that the key steps are cut first and the tumbler-slots afterwards. We may here remark that bit, or bitt, is the name given, somewhat indefinitely, either to the whole flat part of a key, or to the small stepped portions of it. The flat part was formerly termed the ***web*** of the key, probably from the *webbed* appearance of the keys to complex warded locks.

After the reading of Mr. Chubb's paper before the Institution of Civil Engineers, Mr. Owen narrated one or two circumstances connected with the early history of Chubb's lock. A convict on board one of the prison-ships at Portsmouth dockyard, who was by profession a lock-maker, and who had been employed in London in making and repairing locks for several years, and subsequently had been notorious for picking locks, asserted that he had picked with ease one of the best of Bramah's locks, and that he could pick Chubb's locks with equal facility.

One of the latter was secured by the seals of the late Sir George Grey, the Commissioner, and some of the principal officers of the dockyard, and given to the convict, together with files and all the tools which he stated were necessary for preparing false instruments for the purpose, as also blank keys to fit the pin of the lock. A lock exactly the same in principle was placed in his hands, that he might examine it and make himself master of its construction. If he succeeded in opening the lock, he was to receive a free pardon from the Government, and a reward of £100 from Messrs. Chubb.

After trying for two or three months to pick the sealed lock, during which time, by his repeated efforts, he frequently over-lifted the detector, which was as often readjusted for his subsequent trials, he gave up the attempt. He stated that Chubb's were the most secure locks he had ever met with, and that it was impossible for any man to pick or to open them with false instruments.

Mr. Owen further stated, that in order to compare the merits of Bramah's and Chubb's locks, he had suggested a mechanical contrivance, which was applied to one of Bramah's six-spring padlocks belonging to the Excise. It was hung upon a nail, in a vertical position, secure from lateral oscillation. A self-acting apparatus was then applied, consisting of a pipe with hexagonal grooves, and a stud or bit corresponding with the division of the lock, and secured to it by a spring.

In the grooves of this pipe small slides were inserted, which pressed against the spring keys of the lock; to these slides were attached levers, acted upon by eccentrics, moved by a combination of wheels, whose teeth differed in number so as to perform the permutation required for the different depths of the spring keys, corresponding with those of the proper key to the lock. The automaton machine was set in motion by a line working over a barrel, and acted upon by a weight; and was thus left acting upon the mechanism for a considerable time.

At right angles to the pipe or false key was attached a rod and weight; and when the notches in the spring keys were brought in a line with the plane of the plate or diaphragm of the lock, the rod and weight turned the false key, opened the lock, and stopped the further motion of the automaton. In that state the slides indicated the exact depth of the grooves in the proper key, and gave the form of a matrix by which to make a key similar to the original one.

The automaton worked during a period varying from half an hour to three hours, according to the state of permutation of the apparatus at the moment of being applied, compared with that of the slides in the lock. We confess that it is difficult to understand the action of this automaton from Mr. Owen's description. We imagine that the false notches would effectively prevent the operation of the instrument, and openings would be required on each slide to bring it back, so as to meet the motions of the machine.

Mr. Owen did not state whether his apparatus had been successful with one only of Bramah's locks or with several; nor did he describe any apparatus invented with the view to the picking of Chubb's locks. He stated, however, that in order to ascertain the effect of friction on one of these last named locks, it was subjected to the alternate rectilinear motion of a steam-engine in Portsmouth dockyard, and was locked and unlocked upwards of 460,000 times consecutively, without any appreciable wear being indicated by a gauge applied to the levers and the key, both before and after this alternate action.

Mr. Owen concluded by expressing his individual opinion that Chubb's lock had never been picked. "The detector was the main feature of its excellence; and additional precaution, therefore, was only departing from its simplicity, and adding to the expense, without any commensurate advantage."

In a subsequent chapter, the degree of security afforded by various descriptions of locks, and the obstacles which they present of being picked, will come under notice; we therefore now proceed to describe briefly a few other tumbler-locks, or application of the tumbler-principle.

In Mr. Somerford's lock, for which the Society of Arts gave a premium in 1818, an attempt was made to improve upon the ordinary action of tumblers. In most such locks, all the tumblers must ascend, although to different heights, before the stud of the bolt can pass through the slots; "which arrangement," says Mr. Somerford, "gives an opportunity of introducing a nail, or a piece of stout wire into the lock, and thus raising the tumblers without the necessity of using the key." In his new lock, however, he made one lever to ascend while the other descended, by a somewhat complicated arrangement of slotted plates above and below the bolt. The key was so perforated as to be much endangered in respect to strength.

In Davis's lock there is a double chamber with wards on the side of the keyhole. The key is inserted into the first chamber and turned a quarter round; it is then pushed forward into the inner chamber, where there is a rotating plate containing a series of small pins or studs, which are laid hold of by the key. By turning the key, the plate is moved round, the tumbler is raised, and the bolt is shot backwards and forwards. This lock, which is somewhat expensive, is used to some extent on cabinet dispatch-boxes.

The lock invented by Mr. Nettlefold is so constructed, that when the bolt is shot out by the key, two teeth or quadrants are projected from the sides of the bolt, which take a firm hold of the plate fixed on the door-post or edge. This construction is said to answer well for sliding-doors.

Mr. Alfred Ainger, in 1820, received a silver medal from the Society of Arts for a draw-back spring latch, in which the objects proposed were the two following: to render the lock more difficult of violation by a pick than those ordinarily in use; and to apply to it a key of which no ordinary person could take an impress, and which would be difficult of access even in a workman's hand.

The key is very peculiar; its pipe consists of three divisions, the section of the upper and lower divisions being circular, and that of the middle division triangular; the triangular portion is intended to give motion to some part of the interior of the lock during the rotation of the key. There are collars fixed on the extremity of the key, to act each on one tumbler; and there are modes, by varying the arrangement of these collars on an octagonal stem, to give something like a permutation to the number of variations to which the action of the key may be subject. The notches or slots are rather in the bolt than in the tumblers; and there are many peculiarities in the general arrangement.

In a lock invented and patented by Mr. Parsons, the tumblers are of a particular form, being hinged on a pivot at their centers, and working into and out of two notches cut in the under side of the bolt. It must be obvious that many variations in the adjustment of the tumblers of locks might be made, without vitiating the principle on which the action depends.

Many inventors have tried the use of an expanding web to the key,

so planned that if the step of the web be long enough to reach the tumbler, it would be too long to pass through the keyhole; and therefore a principle of safety would operate by enabling the key to adjust itself at one moment to the size of the keyhole, and at another to the height of the tumbler.

Mr. Machin of Wolverhampton invented such a key in 1827. The web of the key is moveable on a countersunk pin, on which it can so far slide as to be drawn one-eighth of an inch from the barrel. The keyhole is of such a size as to admit the key only when the web is pressed close up to the barrel.

When the key in this state is introduced, and is begun to be turned round, one of the notches in the web works into a raised circular edge of steel, placed eccentrically with regard to the lock-pin; so that as the key is turned, the web becomes drawn out, and is at its greatest elongation when it arrives at the tumblers. In the second half of its circular movement, the key becomes contracted to its original dimensions, and can then be removed from the lock.

Another mode of modifying the key has been introduced by Mr. Mackinnon, the object being to enable any person to change at will the pattern or arrangement of the moveable parts of a lock and key; or to keep the key, when not actually in use, in such a state as to render it unavailing to any one but himself. It was a complex arrangement, which does not seem to have come much into use.

The lock invented by Mr. Williams, in 1839, may be designated a pin-lock, involving a principle analogous in many points to that of the Egyptian lock. This lock has a series of pins that reach through the cap, and are pressed to their places with a key like a comb or a rake-head. On the inner end of each pin is a flat piece of steel, in which is cut a notch for the passage of the bolt; but this passage is not clear until the notches in all the pieces of steel are in a right line.

The pins are moveable, and can be pushed either too far or not far enough to bring about the coincidence of position in the notches; and on this ground they are "double-acting." Now the teeth of the key are of irregular lengths, each having a length just suited for pushing the pin to the proper depth: any other lengths of teeth would fail to open the lock. There is a mechanism of springs and levers to shoot the bolt when the pins in the plate are rightly adjusted.

The arrangements in respect to the key are singular and somewhat awkward. The teeth that lock the bolt are not the same as those which unlock it, the user having to change ends and adjust the bit to a socket-handle. This is one among many examples in which a lock embodies several principles, the inventor having set himself the task of combining the excellence of many diverse locks.

In respect to the tumbler-locks generally, the simplicity of action, the strength of construction, and the non-liability of disarrangement, have given them a high place among safety-locks. The only danger seemed to be, that any person once obtaining possession of the key could take an impression from it, and thence form a key which would command the lock.

Attempts have been occasionally made to obviate this danger, by supplying the key with moveable bits that could be changed at pleasure, so as to constitute any number of effectively different bits in succession. But the locks being so constructed that the bolt could only be moved when the tumblers were in a certain position, the owner was placed in this predicament: that it was useless to alter the arrangement of the bits in the key, unless the tumblers were altered in a corresponding manner; and this would entail the removal of the lock from the door, and the rearrangement of the interior mechanism.

One of the great defects of tumbler-locks made previously to the last ten years was, that the tumblers, when lying at rest in the lock, presented at their ***bellies*** or lower edges precisely the same arrangement as the steps of the key. Indeed, in many locks of the present day, a good idea of the form of the key may be gained by feeling the bellies of the tumblers. The bellies are in fact cut out so as to compensate for the circular motion of the key, to allow them to remain at rest while the stump is passing through the gating. Even in tumbler-locks of the best construction, the tumblers will vibrate more or less during the motion of the key; a defect which must be provided against in adjusting the lock, or the stump will be caught in its passage through the gating.

Mr. Hobbs provides a simple remedy by enlarging the back part of the gating, the effect of which is as follows: when, in shooting back the bolt, as in unlocking, the key has got to its highest point, the stump enters the narrow end of the gating: but in shooting the bolt forward, as in locking, the stump enters the

gating before the key has got to its highest point, and to allow for the slight vibratory motion of the tumblers during the passage of the stump, the gating is widened.

The usual method of adjustment is to alter the forms of the bellies of the tumblers, thus greatly risking the security of the lock, a defect which was clearly perceived by Bramah, and was one of the reasons which induced him to construct locks with slides instead of tumblers.

American locks on the tumbler-principle, and the relation which all such locks bear to the Bramah lock, will be better understood after the details of the following chapter.

CHAPTER SIX: The Bramah Lock

MASTER EXHIBIT LIST

THE lock which was invented by the late Mr. Bramah deservedly occupies a high place among this class of contrivances. It differs very materially from all which has gone before it; its mechanical construction is accurate and beautiful; its key is remarkable for smallness of size; and the invention was introduced by the publication of an essay containing much sensible observation on locks generally. The full title of this essay runs thus:

"A dissertation on the Construction of Locks. Containing, first, reasons and observations, demonstrating all locks which depend upon fixed wards to be erroneous in principle, and defective in point of security. Secondly, a specification of a lock, constructed on a new and infallible principle, which, possessing all the properties essential to security, will prevent the most ruinous consequences of house-robberies, and be a certain protection against thieves of all descriptions." A second

edition of this *Dissertation was* published in 1815; but the work is now extremely scarce, and hardly attainable."

It is remarkable to observe the boldness and self-relying confidence with which Mr. Bramah, some sixty years ago, declared that *all* locks were, up to that time, violable; he felt that this was strictly true, and he hesitated not to give expression to his conviction. The following is from his *Dissertation:*

"It is observable that those who are taken in the desperate occupation of house-breaking are always furnished with a number and variety of keys or other instruments adapted to the purpose of picking or opening locks; and it needs no argument to prove that these implements must be essential to the execution of their intentions. For unless they can secure access to the portable and most valuable part of the effects, which in most families are deposited under the imaginary security of locks, the plunder would seldom recompense the difficulty and hazard of the enterprise; and till some method of security be adopted by which such keys and instruments may be rendered useless, no effectual check or opposition can be given to the excessive and alarming practice of house-breaking."

"Being confident that I have contrived a security which no instrument but its proper key can reach; and which may be so applied as not only to defy the art and ingenuity of the most skilful workman, but to render the utmost force ineffectual, and thereby to secure what is most valued as well from dishonest servants as from the midnight ruffian, I think myself at liberty to declare (what nothing but the discovery of an infallible remedy would justify my disclosing), that all dependence on the inviolable security of locks, even of those which are constructed on the best principle of any in general use, is fallacious."

"To demonstrate this bold and alarming proposition, I shall first state the common principles which are applied in the art of lock-making; and by describing their operation in instruments differently constructed, prove to my intelligent readers that the best-constructed locks are liable to be secretly opened with great facility; and that the locks in common use are calculated only to induce a false confidence in their effect, and to throw temptation to dishonesty in the way of those who are acquainted with their imperfections, and know their inefficacy to the purpose of security"

Tumblers had been so little thought of and used at the time

Bramah wrote, that his attention was almost exclusively directed to *warded* locks. The mysterious clefts in a key, connected with some kind of secret mechanism in the lock, had given the warded locks a great hold on the public mind, as models of puzzlement and security; and it was to show that this confidence rested on a false basis, that he to a great extent labored. The following is his exposition of the principle and the defects of the warded lock.

"Locks have been constructed, and are at present much used and held in great esteem, from which the pick-lock is effectively excluded; but the admission of false keys is an imperfection for which no locksmith has ever found a corrective; nor can this imperfection be remedied whilst the protection of the bolt is wholly confided to fixed wards."

"For if a lock of any given size be furnished with wards in as curious and complete a manner as it can be, those wards being necessarily expressed on what is termed by locksmiths the bit or web of the key, do not admit of a greater number of variations than can be expressed on that bit or web; when, therefore, as many locks have been completed of the given size as will include all the variations which the surface of the bit will contain, every future lock must be the counterpart of some former one, and the same key which opens the one will of course unlock the other."

"It hence follows that every lock which shall be fabricated on this given scale, beyond the number at which the capability of variation ends, must be as subject to the key of some other lock as to its own; and both become less secure as their counterparts become more numerous. This objection is confirmed by a reference to the locks commonly fixed on drawers and bureaus, in which the variations are few, and these so frequently repeated, from the infinite demand for such locks, that, even if it were formed to resist the pick-lock, they would be liable to be opened by ten thousand correspondent keys. And the same observation applies in a greater or less degree to every lock in which the variations are not endless."

"But if the variation of locks in which the bolt is guarded only by fixed wards could be multiplied to infinity, they would afford no security against the efforts of an ingenious locksmith; for though an artful and judicious arrangement of the wards, or other impediments, may render the passage to the bolt so intricate and perplexed as to exclude every instrument but its

proper key, a skilful workman having access to the entrance will be at no loss to fabricate a key which shall tally as perfectly with the wards as if the lock had been open to his inspection."

"And this operation may not only be performed to the highest degree of certainty and exactness, but is conducted likewise with the utmost ease. For the block or bit, which is intended to receive the impression of the wards, being fitted to the keyhole, and the shank of the key bored to a sufficient depth to receive the pipe, nothing remains but to cover the bit with a preparation which, by a gentle pressure against the introductory ward, may receive its impression, and thus furnish a certain direction for the application of the file."

"The block or bit being thus prepared with a tally to the first ward, gains admission to the second; and a repetition of the means by which the first impression was obtained, enables the workman to proceed, till by the dexterous use of his file he has effected a free passage to the bolt. And in this operation he is directed by an infallible guide; for, the pipe being a fixed center on which the key revolves without any variation, and the wards being fixed likewise, their position must be accurately described on the surface of the bit which is prepared to receive their impression."

"The key therefore may be formed and perfectly fitted to the lock without any extraordinary degree of genius or mechanical skill. It is from hence evident that endless variations in the disposition of fixed wards are not alone sufficient to the purpose of perfect security. I do not mean to subtract from the merit of such inventions, nor to dispute their utility or importance. Every approach towards perfection in the art of lock-making may be productive of much good, and is at least deserving of commendation; for if no higher benefit were to result from it, than the rendering difficult or impossible to many that which is still practicable and easy to a few, it furnishes a material security against those from whom the greatest mischief and dangers are to be apprehended."

There can be little doubt, in the present day, that Bramah did not over-rate the fallacies embodied in the system of wards for locks. He was sufficiently a machinist to detect the weak points in the ordinary locks; and, whatever may have been his over-estimate of his own lock (presently to be described), he was certainly guilty of no injustice to those who had preceded him; for their locks were substantially as he has described them.

To understand the true bearings of his Dissertation too, we must remember that housebreaking had risen to a most daring height in London at the time he wrote (about the middle of the reign of George III.); and men's minds were more than usually absorbed by considerations relating to their doors and locks.

"Mr. Bramah, after doing due justice to the ingenuity of Barron's lock, in which, if the tumbler be either *over*-lifted or *under*-lifted, the lock cannot be opened, pointed out very clearly the defective principle which still governed the lock. "Greatly as the art is indebted to the ingenuity of Mr. Barron, he has not yet attained that point of excellence in the construction of his lock which is essential to perfect security. His improvement has greatly increased the difficulty but not precluded the possibility of opening his lock by a key made and obtained as above described (by a wax impression on a blank key); for an impression of the tumblers may be taken by the same method, and the key be made to act upon them as accurately as it may be made to tally with the wards.”

“Nor will the practicability of obtaining such a key be prevented, however complicated the principle or construction of the lock may be, whilst the disposition of its parts may be ascertained and their impression correctly taken from without. I apprehend the use of additional tumblers to have been applied by Mr. Barron as a remedy for this imperfection."

Mr. Bramah thought that Barron had a perception of a higher degree of security, but had failed to realize it; because, by giving a uniform motion to the tumblers, and presenting them with a face which tallies exactly with the key, they still partake in a very great degree of the nature of fixed wards, and the security of the lock is thereby rendered in a proportionate degree defective and liable to doubt.

To show how this insecurity arises, Mr. Bramah illustrates the matter in the following way: "Suppose the key with which the workman is making his way to the bolt to have passed the wards, and to be in contact with the most prominent of the tumblers: The impression, which the slightest touch will leave on the key, will direct the application of the file till sufficient space is prepared to give it a free passage. This being accomplished, the key will of course bear upon the tumbler which is most remote; and being formed by this process to tally with the face which the tumblers present, will acquire as perfect a command of the lock

as if it had been originally made for the purpose. And the key, being thus brought to a bearing on all the tumblers at once, the benefit arising from the increase of their number, if multiplied by fifty, must inevitably be lost; for, having but one motion, they act only with the effect of one instrument."

It is worthy of notice, that even while thus showing the weak points of the Barron lock, Mr. Bramah seems to have had in his mind some conception of infallibility or inviolability attainable by the lock in question. After speaking of the defect arising from the bad arrangement of the tumblers, he says: "But nothing is more easy than to remove this objection, and to obtain perfect security from the application of Mr. Barron's principle."

"If the tumblers, which project unequally and form a fixed tally to the key, were made to present a plane surface, it would require a separate and unequal motion to disengage them from the bolt; and consequently no impression could be obtained from without that would give any idea of their positions with respect to each other, or be of any use even to the most skilful and experienced workman in the formation of a false key. The correction of this defect would rescue the principle of Mr. Barron's lock, as far as I am capable of judging, from every imputation of error or imperfection; and, as long as it could be kept unimpaired, would be a perfect security."

"But the tumblers, on which its security depends, being of slight substance, exposed to perpetual friction, as well from the application of the key as from their own proper motion, and their office being such as to render the most trifling loss of metal fatal to their operation, they would need a further exertion of Mr. Barron's ingenuity to make them durable."

It may perhaps be doubted whether the principle of Bramah's lock is not more clearly shown in the original constructed by him than in that of later date. In appearance it is totally different, but the same pervading principle is observable in both; and the cylinder lock can certainly be better understood when this original flat lock has been studied. The annexed woodcut is taken from the first and very scarce edition of Mr. Bramah's *Dissertation;* the description is somewhat more condensed, but perhaps sufficient for the purpose.

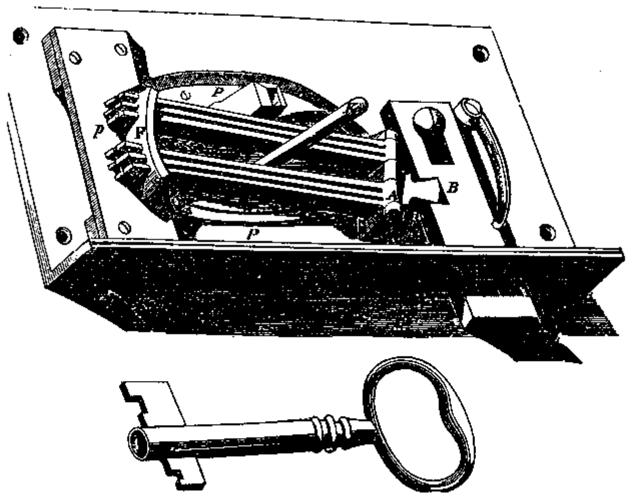

Figure 33 Bramah's first model.

The lock is supposed to be lying flat, with the bolt **B** half-shot. Ranged somewhat diagonally are six levers, turning on a horizontal joint or pivot at **A**, each lever having a slight extent of vertical motion independent of the others. Each lever rests on a separate spring of sufficient strength to sustain its weight, or, if depressed by a superior force, to restore it to its proper position when the force is withdrawn.

F *is* a curved piece of metal, pierced with six grooves or passages; these grooves are exactly equal in width to the thickness of the levers, but are of sufficient depth to allow the levers a free motion in a perpendicular direction. The ends of the levers are inserted in these grooves, and have this freedom of motion, whether lifted by the elastic power of the springs or depressed by a weight from above. In the bolt *B is* a notch to receive a peculiarly-shaped lever, which shoots or withdraws the bolt according as it traverses to the right or the left.

This lever, the six long levers, the springs beneath them, the bent piece **F**, and the pivot, all alike are fixed to a circular platform **P**, which turns on a center; so that if any force can make this platform turn partially round, the bolt must be shot or unshot by the lever which works in the notch.

The six long levers are the contrivances whereby the platform shall *not* be allowed to turn until the proper moving agent (the key) shall have been applied, the plate **p** being one of the assistants in this obstruction. This plate, which is hollow underneath, has six notches in one of its edges; the points of

the levers catch into these notches; and while so caught, the levers cannot move horizontally, and all the machinery is at a stand-still.

To enable the key to set the mechanism in action, other contrivances are necessary. Each lever has a notch at its extreme end, and the six are notched very irregularly in respect one to another. These notches must be brought all into one plane, to enable the levers to pass horizontally out of the notches in the plate, in the same way as the two prongs of a fork might traverse, one above and the other below the blade of a knife; and when the lever-notches are in this position, all in one plane and in the plane of the plate, the levers can be moved, and with it the stump which shoots the bolt.

To ensure this due pressing down of the levers, a key is used such as is shown in the cut, having six steps or bits to correspond with the six levers; this key, put upon the pin **K**, presses down all the levers to the exact distance necessary for bringing the notches into one plane, viz. the plane of the plate; the key then being turned round, turns the moveable platform **P**, and shoots the bolt.

It is evident at a glance, that unless the various steps of the key are so cut, that each shall press down its own lever to the proper extent, the ends of the levers cannot pass the notches in the plate, and the bolt can neither be locked nor unlocked.

It may be well to give Bramah's own words in relation to this lock: "I may safely assert that it is not in art to produce a key or other instrument by which a lock constructed on this principle can be opened. It will be a task, indeed, of great difficulty, even to a skilful workman, to fit a key to this species of lock, though its interior face were open to his inspection; for the levers being raised by the subjacent springs to an equal height present a *plane* surface, and consequently convey no direction that can be of any use in forming a tally to the *irregular* surface which they present when acting in subjection to the proper key."

"Unless, therefore, a method be contrived to bring the notches on the ends of the levers in a direct line with each other, and *to retain them in that position till an exact impression of the irregular surface which the levers will then exhibit can be taken,* the workman will in vain attempt to fit a key to the lock, or by any effort of art to move the bolt."

"And when it is considered that this process will be greatly impeded, and may perhaps be entirely frustrated by the action of the springs, it must appear that great patience and perseverance, as well as great ingenuity, will be required to give any chance of succeeding in the attempt."

"I do not state this circumstance as a point essential or of any importance to the purpose of the lock, but to prove more clearly what I have before observed upon its principle and properties; for if such difficulties occur to a skilled workman, as to render it almost, if not altogether impracticable to form a key when the lock is open to his inspection and its parts accessible to his hand, it pretty clearly demonstrates the impossibility of accomplishing it when no part of the movement can be touched or seen."

It is evident that Mr. Bramah had his thoughts directed to that mode of picking locks which depends on taking impressions of the moving parts, rather than to the *mechanical* or *pressure* method which has been developed in later times. There can be little doubt that a lock was, to his mind, a beautiful and admirable machine, far elevated above the level of mere blacksmith's work; and his name will ever be associated with what may be termed the philosophy of lock-making.

After the model-lock, which has just been described, was constructed, and found to corroborate the idea which was working in Mr. Bramah's mind, he proceeded to the construction of his barrel or cylinder-lock, embracing similar elements placed in more convenient juxtaposition. In his Essay he gives an engraving to illustrate the principle on which his lock acts, rather in the manner of a diagram than as depicting any lock actually made; his main object being to impart a clear notion of the action of the slides which form such a distinguishing feature in his lock.

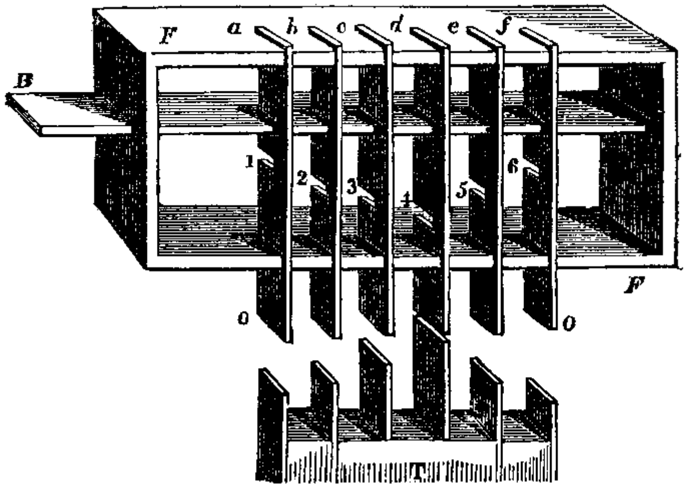

Figure 34 Diagram to illustrate the Bramah lock.

Viewed in this sense, therefore, simply as an illustrative diagram, the annexed cut may represent the action of the safety slides. **B** is a sliding bar or bolt, having a power of longitudinal motion in the frame **F**. This frame has six notches cut on each of its long sides, the two series being exactly opposite each other; and there are six similar notches cut in the bolt **B**.

The concurrent effect of all these eighteen notches is, that the six slides ***abcdef*** can move freely up and down across the bolt. When the slides are thus placed, the bolt cannot move, and may in this case be considered to be locked. There are six clefts or notches in the six slides, one to each (1, 2, 3, 4, 5, 6); and until all these are brought in a right line, the bolt cannot move through them. If a tally or key be prepared, as shown at **T** in the lower part of the cut, with six projections, and if these projections thrust up the six slides until their clefts rise to the plane of the bolt, then can the bolt be withdrawn or the lock opened. This serves to illustrate the relation between the slides and the key, as carried out in the way now to be described.

One peculiar peculiarity of the Bramah lock is, that from the essential part of the apparatus being a barrel or cylinder, much of the working can be conducted in the lathe; and this has given a beauty to the details generally and deservedly admired.

Mr. Bramah, when he worked out the theory of his lock, resolved to discard altogether the use of fixed wards, and also the use of tumblers working on a pivot at one end; substituting in their

stead a system of slides, working in a very novel way.

The body of a Bramah lock may be considered as formed of two concentric brass barrels, the outer one fixed, and the inner rotating within it. The inner barrel has a projecting stud, which, while the barrel is rotating, comes in contact with the bolt in such a way as to shoot or lock it; and thus the stud serves the same purpose as the bit of an ordinary key, rendering the construction of a bit to the Bramah key unnecessary.

If the barrel can be made to rotate to the right or left, the bolt can be locked or unlocked; and the problem is, therefore, how to ensure the rotation of the barrel. The key, which has a pipe or hollow shaft, is inserted in the keyhole upon the pin, and is then turned round; but there must be a very nice adjustment of the mechanism of the barrel before this turning round of the key and the barrel can be ensured.

The barrel has an external circular groove at right angles to the axis, penetrating to a certain depth; and it has also several *internal* longitudinal grooves, from end to end. In these internal grooves thin pieces of steel are able to slide, in a direction parallel with the axis of the barrel.

A thin plate of steel, called the locking-plate, is screwed in two portions to the outer barrel, concentric with the inner barrel; and at the same time occupying the external circular groove of the inner barrel. This plate has notches, fitted in number and size to receive the edges of the slides which work in the internal longitudinal grooves of the barrel.

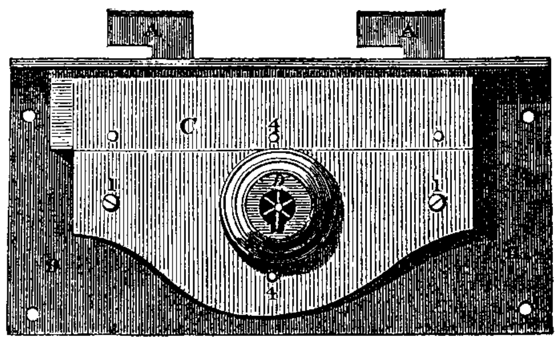
If this were all, the barrel could not revolve, because the slides are catching in the grooves of the locking-plate; but each slide also has a groove, corresponding in depth to the extent of this entanglement; and if this groove be brought to the plane of the locking-plate, the barrel can be turned, so far as respects that individual slide.

All the slides must, however, be so adjusted that their grooves shall come to the same plane; but as the notch is cut at different points in the lengths of the several slides, the slides have to be pushed in to different distances in the barrel, in order that this juxtaposition of notches may be ensured.

This is effected by the key, which has notches or clefts at the end of the pipe equal in number to the slides, and made to fit

the ends of the slides when the key is inserted.

The key presses each slide, and pushes it so far as the depth of its cleft will permit; and all these depths are such that all the slides are pushed to the exact position where their notches all lie in the same plane; this is the plane of the locking-plate, and the barrel can be then turned.



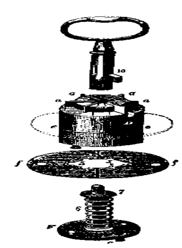


Figure 35 Exterior of a Bramah lock.

This is the principle which Mr. Bramah adopted; and we have now to trace it, step by step, by means of illustrative details. **Figure 35** represents the exterior of a box or desk lock, one among many varieties which the Bramah lock presents. **A A** shows the bolt, formed something like two hooks rising out of a bar of metal, which bar has a backward and forward motion upon the plate **B B.**

The upper edge of this plate is turned over at right angles, forming a small horizontal surface through which two openings are cut to receive the two hooked portions of the bolt. The movements of the bolt are otherwise guided by the edges of square holes through which it works; the holes being made in the edge-pieces of the lock, riveted to the main plate.

The bolt is further prevented from rising out of its place by means of a plate of metal **c**, which is secured to the edge pieces by two screws **1,l**, and by two steadying pieces. This plate has on its surface a cylindrical projection **D**, which contains in effect all the working mechanism of the lock.

The pins **4 4** are employed for securing a plate, which we shall have to describe presently. When such a lock is fixed upon a desk or box, the portion **D** projects to a small distance through a hole in the wood-work, forming in itself a very neat escutcheon, with a keyhole in the center

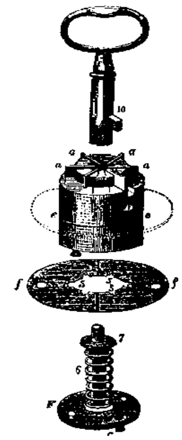

Figure 36. De

So much for the exterior. We must now proceed to examine the interior of the lock, especially the part contained within the cylinder. In **figure 36**, for convenience of arrangement, the several parts are exhibited separately, and as if the plane of the lock were horizontal, with the key acting vertically.

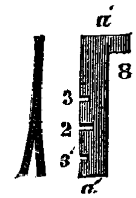

Figure 37

The essential part of the mechanism is a barrel or cylinder **E**, pierced or bored with a cylindrical hole down its center. The inside of the bore has six narrow grooves, cut parallel with the axis, and in the direction of radii; the grooves are not cut through the thickness of the cylinder, but leave sufficient substance of metal for strength.

In every groove is fitted a steel slide of peculiar form, such as is shown at ***a a*** in **figure 37**. Each slide is split in its thickness (seen in section), so that it may move up and down in its groove with a slight friction; the slides, thereby not falling simply by its own weight.

Each slide has three small notches (3, 2, 3), the use of which will presently appear. Reverting to **figure 86**, the lower part of the opening through the cylinder **E** is closed by a circular plate of metal, fixed to it by two screws; this plate is represented at **ii**, in the lower part of the figure.

This plate has a vertical pin rising from its center (also seen at **b**, **figure 39**), and serving as a key-pin on which the pipe of the key may work or slide; and it has also a short circular stud **e** projecting from its underside, and fitted to enter into a curved opening in the bolt presently to be described.

The point to be now borne in mind is this, that if the cylinder **E** turns round, the plate **F** will also turn round, and with it the stud **c**; and as this stud works into the peculiarly formed cavity **d** in. *a* portion of the bolt (**figure 38**), it causes the bolt to be shot backwards or forwards.

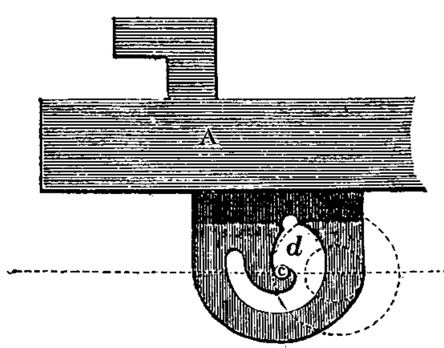

Figure 38 The bolt.

Now, in order to prevent this rotating of the cylinder unless the

proper key be employed, the following mechanism is introduced: the cylinder has a groove cut round its circumference at ***e e,*** extending sufficiently near to the internal bore to produce the desired effect without too much weakening the metal.

Into this notch is introduced the thin circular plate of metal **ff**, it being divided into two halves for this purpose; and when so placed, it occupies the position shown by the dotted portion ***e e.***

When this plate is screwed to the case of the lock by the screws **4, 4,** it cannot of course turn round; but the cylinder itself will or will not turn round according to the position of the slides. The plate ***ff*** has six notches, **5, 5, 5,** etc. in the inner edge or circle; so adjusted that, when the plate is in its place, the slides **a a** can move up and down.

The cylinder cannot move round in a circle without carrying the slides with it; and these cannot so move unless they are all depressed to such exact distances in their respective grooves, that the deep notch of each slider (shown at **2** in **figure 37**) shall come into the plane of the circular plate; when all are so brought, the cylinder can be turned.

If any one of the slides be pressed down either too low or not low enough, this turning of the cylinder cannot be effected, because the slides will be intersected by the edges of the notches **5, 5**; and it is the office of the key, therefore, to press all the six slides down to the exact distances required.

When the slides are not pressed upon by the key, they are forced upwards to the top of the cylinder by a spiral spring **6,** coiled loosely round the pin **b**; this pressure forces up a small collet, **7,** on which the upper part of the slides rest by a sort of step.

The first locks were made with a separate and independent spring to each slide; but it is a very great improvement, the introduction of one common spring to raise up the whole number; because if a person attempts to pick the lock by depressing the slides separately by means of any small pointed instruments, and by chance brings two or more of them to the proper depth for turning round, should he press any one too low, it is difficult to raise it again without relieving the spring **6,** which immediately throws the whole number of slides up to the top, and destroys all that had been done towards picking the lock.

Another improvement of this lock, and one which very much increased the difficulty of picking, and its consequent security, was the introduction of false and deceptive notches cut in the sliders, as seen at **3, 3**. It was found that in the attempt to pick this lock, an instrument was introduced by the keyhole to force the cylinder round.

At the same time that the slides were depressed by separate instruments, those slides which were not at the proper level for moving round were held fast by the notches **5, 5** in the plate **ff** against their sides; but when pressed down to the proper level, or until the notch **2** came opposite **ff** they were not held fast, but were relieved.

This furnished the depredator with the means of ascertaining which slides were pressed low enough, or to the point for unlocking. The notches **3, 3** in the slides are sometimes cut above the true notch **2**, sometimes below, and at other times one on each side (one above and one below).

They are not of sufficient depth to allow the cylinder to turn round, but are intended to mislead anyone who attempts to pick, by his not knowing whether it is the true notch or otherwise, or even whether the slider be higher or lower than the true notch.

We have not yet sufficiently described the key of the Bramah lock. One merit of the lock is the remarkable smallness of the key, which renders it so conveniently portable. The key, as shown in the upper part of the figure, has six notches or clefts at the end of its pipe or barrel; these clefts are cut to different depths, to accord with the proper extent of movement in the slides.

There is a small projection, **10**, near the end of the pipe, fitted to enter the notch **D** in the cylinder; this forces the cylinder round when the parts are all properly adjusted. The bolt of the lock, when properly shot or locked, is prevented from being forced back by the stud **c** on the bottom, **F**. of the cylinder coming into a direct line with its center of motion, as shown in **figure 39**; in this position no force, applied to drive the bolt back, would have any tendency to turn the cylinder round.

To facilitate the comprehension of this very curious and beautiful mechanism, the cylinder is shown in section in the annexed **figure 39**, the same letters and figures of reference being used as before. In the whole of this description, we have

spoken of six slides, and six only; but Bramah locks may be, and have been, constructed with a much larger number.

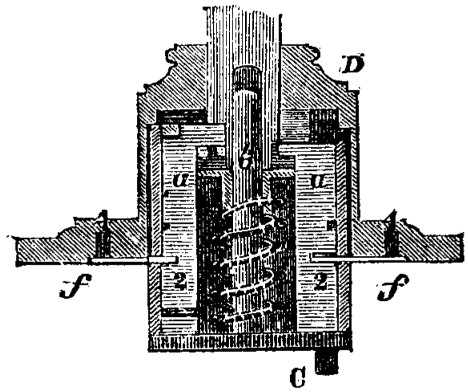

Figure 39 Section of the Bramah cylinder.

There have been several attempts made to modify the action of Bramah's lock, or to combine this action with that of some other inventor. It will suffice to describe one of these. The lock invented by Mr. Kemp of Cork, and for which a patent was obtained in 1816, is called by him the **Union lock**, as combining the principles of Barron's and Bramah's locks.

It contains two, three, or more sliders or tumblers, operated upon by two, three, or more concentric tubes. These concentric tubes are of different lengths, and are placed inside the barrel of the key; so that the barrel may, in fact, be conceived to consist of a series of concentric tubes. These tubes are made of such respective lengths as to push back the tumblers, sliders, or pins which detain the bolt; and this to the precise extent that will bring certain notches in all the sliders to the position which will allow the bolt to pass.

The inventor gives this lock its distinctive appellation because it combines something of the pushing motion which, Bramah gives to his key, with something of the tumbler-motion observable in Barron's locks. The principle of security is considered here to rest chiefly on the extreme difficulty of imitating the key.

Mr. Bramah calculates the number of changes of position of which the slides of his lock are capable of assuming before the right one would be attained. "Let us suppose the number of levers, slides, or other movables by which the lock is kept shut, to consist of twelve, all of which must receive a different and distinct change in their position or situation by the application of the key, and each of them likewise capable of receiving more

or less than its due, either of which would be sufficient to prevent the intended effect.

It remains, therefore, to estimate the number producible, which may be thus attempted. Let the denomination of these slides be represented by twelve arithmetic progressions; we find that the ultimate number of changes that may be made in their place or situation is 479,001,600.

By adding one more to that number of slides, they would then be capable of receiving a number of changes equal to 6,227,020,800; and so on progressively, by the addition of others in like manner to infinity.

From this it appears that one lock consisting of thirteen of the above-mentioned sliders, may (by changing their places only, without any difference in motion or size), be made to require the said immense number of keys, by which the lock could only be opened under all its variations."

CHAPTER SEVEN: American Locks

MASTER EXHIBIT LIST

Hobbs closed keyhole lock

THE lock-manufacture in America has undergone some such changes as in England. The insufficiency of wards to the attainment of security has been for many years known; and the unfitness of even tumblers to attain this end, without auxiliary contrivances, has been fully recognized for a dozen years back.

In this, and in other mechanical arts, the American machinists depended primarily on the invention of the artisans in the mother country, rather than on those of any continental European state. But the development of the art in the United States has not been wanting in originality; the varieties of locks have been very numerous, and many of them exceedingly ingenious. It is not necessary, however, to describe or depict any of those of simple form.

The warded locks of different countries very much resemble each other; the intricate warded locks made in France in the last century have long fallen into disuse, in consequence of the general conviction that no arrangement of wards, however intricate, can afford the degree of security required in a good lock. It will be more to the purpose, therefore, to proceed at once to a notice of those American locks that, during the last few years, have acquired some celebrity; first, however, noticing one of older date.

Stansbury's lock, invented in the United States about forty years ago, may be regarded as a modification of the Egyptian lock. It had a bolt, case, and keyhole somewhat similar to those of modern locks; but there were peculiarities of construction in other respects. There was a revolving plate, pierced with a series of holes, and having a bit or pin that moved the bolt. On the lock-case were a series of springs, each having a pin at one end; and the arrangement was such that, when the bolt was locked or unlocked, each pin would be pressed into some one of the holes.

Like as in the Egyptian lock (**figures 1 to 4**), each pin had to be pushed out, and all of them simultaneously, to allow the plate to turn and move the bolt. The key was made with a barrel and bit; and on the front end of the bit was a series of pins corresponding in position with the holes in the plate. The mode of locking or unlocking was as follows: the key was inserted in the keyhole, and turned to a certain position; it was then pressed in with some force, until the pins on the key met those in the plate; when the latter, yielding to the pressure, left the

plate free to turn and move the bolt.

Modifications of the Egyptian lock, more or less resembling this, have been brought out in some variety on both sides of the Atlantic; but scarcely any have equaled in simplicity the curious wooden relic of by-gone ingenuity in the art of lock-making.

A lock made a few years ago by Mr. Yale, in the United States, somewhat resembles the Bramah lock in having a cylinder or barrel, or rather two concentric cylinders, one working within the other. These cylinders are held together by pins that pass through them both into the keyhole. On the back of the inner cylinder is a pin that fits into a slot in the bolt, and moves it whenever the cylinder is turned.

The pins that hold the cylinders together are each cut in two; the pieces of the various pins differing in lengths as irregularly as possible. The key is so peculiarly formed, that, on inserting it in the keyhole, it thrusts the pins radially outwards; each pin being pushed just so far that the joint of the pin shall coincide with the joint between the two cylinders. The inner cylinder can then be turned, by which the bolt is locked or unlocked. If, by the use of a false key, any pin be pushed in too far, it will be as ineffectual in opening the lock as if it were not thrust in far enough; and some of these locks having been made with as many as forty pins, the chances are very numerous against the right combination being hit upon. There is a combination of something like the Egyptian with something like the Bramah lock, here attempted.

One of the principal constructions adopted in America a few years back for bank-locks is that of Dr. Andrews of Perth Amboy, in New Jersey. It was up to that time (1841) believed that the best locks, both of England and America, were proof against any attempts at picking derived from knowledge obtained by inspection through the keyhole; but there still remained the danger that the sight of the true key, or the possession thereof, for only a few minutes, would enable a dishonest person to produce a duplicate.

It was to contend against this difficulty that Dr. Andrews directed his attention; and he sought to obtain the desired object by constructing a lock, the interior mechanism of which could be changed at pleasure. The lock of his invention is furnished with a series of tumblers and a detector. The tumblers are susceptible of being arranged in any desired order; and the key has moveable bits that can be arranged so as to correspond

with the tumblers. When the lock is fixed in its place, no change can be made in the tumblers, and consequently only one arrangement of the bits of the **key** will suit for the shooting and withdrawing of **the bolt**.

The owner can, however, before the fixing of the bolt, adopt any arrangement of tumblers and bits which he may choose. But though the tumblers cannot be actually rearranged in any new order within the lock while the latter is fixed, yet by an ingenious contrivance the tumblers can be so acted upon as to render the lock practically different from its former self.

The purchaser receives with his lock a series of small steel rings, each ring corresponds in thickness with the thickness of some one of the bits of the key; so that, by suitable adjustment, any one of the bits may be removed from the key, and a ring be substituted in its place. The effect of this substitution is, that the particular tumbler that corresponds with the ring is not raised by it; it is drawn out with the bolt, as if it were part of the bolt itself.

Supposing the lock to be locked by this means, the original key would not now unlock it; for one of the tumblers has now been displaced, and can only be readjusted by the same ring which displaced it. If an attempt is made to open the lock by the original key, or by the key in its original adjustment, a detector is set in action, which indicates that a false key or other instrument has been put into the lock.

One, or more than one of the bits may be removed from the key, and rings be substituted, and consequently one or more of the tumblers may be disturbed in this peculiar way; so that the lock may change its character in all those permutating varieties which are so observable in most "safety-locks."

The shape of the tumblers is, of course, such as to facilitate this action; they have each an elongated slot, and also two notches; when a tumbler is raised by one of the bits of the key, one of the notches closes around a stump fitted into the case of the lock, and prevents the tumbler from being moved onward with the bolt; but when a ring has been substituted for a bit on the key, the tumbler cannot be raised at all; it is carried onward by a stump on the bolt.

Dr. Andrews is also the inventor of a lock that he terms the ***snail-wheel*** *lock.* In this lock a series of revolving discs, or

wheels, taking the place of the tumblers, are mounted on a central pin, on which the pipe of the key is inserted. Each disc has a piece cut out of it, into which the bit of the key enters, and in turning round moves the discs according to the various lengths of the steps on the key. On the outer edge of each disc is a notch, and by the turning of the key all these notches are brought into a line, so that a moveable tongue, or *toggle,* attached to the bolt, falls into the notches; the key is then turned the reverse way, by which means the bolt is projected.

About the time when Dr. Andrews invented his first lock, Mr. Newell, of the firm of Day and Newell of New York, constructed a lock which possessed the same distinctive peculiarity as that of Andrews, viz. that the key might be altered any number of times without rendering it necessary to remove the lock or change its internal mechanism. This was brought about, however, in a different manner. Instead of having, as in the Andrews lock, a two-fold movement to every tumbler, Mr. Newell employed two sets of tumblers, the one set to receive motion from the other, and having different offices to fill, to be acted upon by the key in respect to the first series, and to act upon the bolt in respect to the second.

Calling these two sets *primary* and *secondary,* the action of the lock may he briefly described as follows: A primary tumbler being raised to the proper height by the proper bit in the key, raises the corresponding secondary tumbler; the secondary tumbler is held up in a given position during the locking, while the primary becomes pressed by a spring into its original position. It results from this arrangement that the bolt cannot be unlocked until the primary tumbler has been raised to the same height as before, so as to receive the tongue of the secondary tumbler. And as this is the case in respect to any one primary and its accompanying secondary tumblers, so is it the case whether each set comprises four, five, or any other number. The key may be altered at pleasure, and will in any form equally well shoot the bolt; but the lock can only be unfastened by that arrangement of key that fastened it.

It is, however, desirable to trace the course of improvements more in detail, because every successive change illustrates one or other of the several properties required in a good lock. Messrs. Day and Newell's lock was not finally brought to an efficient form without many attempts more or less abortive.

Mr. Newell conceived the idea of applying a second series of

tumblers, so placed as to be acted upon by the first series. Each of these secondary tumblers had an elongated slot, such that a screw could pass through all of them; the screw having a clamp to overlap the tumblers on the inside of the lock. The head of the screw rested in a small round hole on the back of the lock, so placed as to form a secondary keyhole, to which a small key was fitted.

There was thus a double system of locking, effected in the following way: when the large key had been applied, and had begun to act on the primary tumblers, the small key was used to operate on the clamp-screw, and thus bind all of the secondary tumblers together, ensuring their position at the exact heights or distances to which the primary key had caused them to be lifted. The bolt was then free to be shot, and the first series of tumblers reverted to their original position.

But such an arrangement has obvious inconveniences. Few persons would incur the trouble of using two keys; and besides this, there were not wanting certain defects in the action and reaction of the several parts; for if the clamp-screw were to be left unreleased, the first series of tumblers would be upheld by the second series in such a way that the exact impression of the lengths of the several bits of the key could be obtained through the keyhole while the lock was unlocked or the bolt upshot.

To remedy one or both of these evils was the next object of Mr. Newell's attention. He made a series of notches or teeth in each of the secondary tumblers, corresponding in mutual distance with the steps or bits of the key; and opposite these notched edges he placed a dog or lever, with a projecting tooth suitable to fall into the notches when adjusted properly in relation to each other. When the key was used, the primary tumblers were raised in the usual way, and acted on the secondary tumblers; these latter were so thrown that the dog-tooth caught in the notches and held them fast, thereby rendering the same service as the clamp-screw and the small key in the former arrangement. No other relative position of the bits of the key could now unlock the lock.

Still, improvement as it was, this change was not enough; Mr. Newell found that his lock, like all the locks that had preceded it, was capable of being picked by a clever practitioner; and candidly admitting the fact, he sought to obtain some new means of security. He tried what a series of complicated wards would do, in aid of the former mechanism; but the result proved unsatisfactory.

His next principle was to provide a number of false notches on the abutting parts of the primary and secondary tumblers, with alterations in other parts of the apparatus. The theory now depended upon was this, that if the bolt were subjected to pressure, the tumblers would be held fast by false notches, and could not be raised by any lock-picking instrument. To increase the security, a steel-curtain was so adjusted as to cover, or at least protect, the keyhole. Great anticipations were entertained of this lock, but they were destined to be negatived. A clever American machinist, Mr: Pettit, accepted Messrs. Day and Newell's challenge (500 dollars to any one who could pick this lock); he succeeded in picking the lock, and thus won the prize.

Once again disappointed, Mr. Newell reexamined the whole affair, and sought for some new principle of security that had not before occurred to him. He had found that, modify his lock how he might, the sharp-eyed and neat-fingered mechanician could still explore the interior of the lock in such a way as to find out the relative positions of the tumblers, and thus adapt their means to the desired end. How, therefore, to shut out this exploration altogether became the problem; how to make a lock, the works of which should be ***parautoptic***, *to* coin a word from the Greek, which should signify *concealed from view.* The result of his labors was the production of the American bank-lock now known by that name. The details of this lock may now conveniently be given.

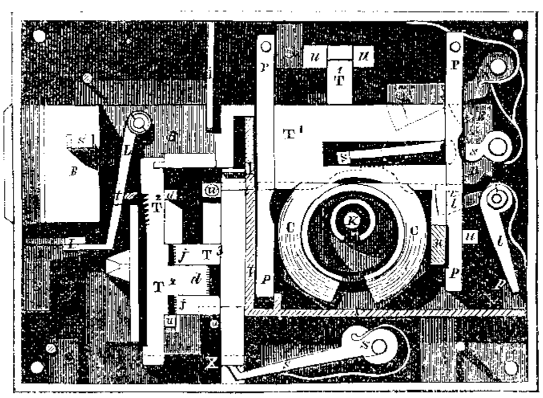

Figure 40 The American Parautoptic lock; bolt upshot.

In **figure 40** the lock is represented in its unlocked state, with the cover or top-plate removed; the auxiliary tumbler and the detector-plate are also removed. In **figure 41** it is represented as locked, with the cover and the detector-plate also removed, and the auxiliary tumbler in its place.

In these two figures, the same letters of reference apply to the same parts, unless otherwise stated. **BB** is the bolt; **T**^{1} are the first series of moveable slides or tumblers; **s** shows the tumbler-springs; **T**^{2} the secondary series of tumblers; and T the third or intermediate series—these latter coming between the first and secondary series; **PP** are the separating plates between the several members of the first series of tumblers; **s**^{1} are the springs for lifting the intermediate tumblers.

On each of the secondary tumblers **T**^{2} is a series of notches, corresponding in mutual distance with the difference in the lengths of the moveable bits of the key. It thence happens that, when the key is turned in the lock to lock it, each bit raises its proper tumbler, so that some one of these notches shall present itself in front of the tooth **t** in the dog or lever **LL**.

When the bolt **B** is projected by the actions of the key, it carries with it the secondary tumblers **T**^{2} and presses the tooth **t** into the notches; in so doing, it withdraws the tongues **d** from between the jaws ***jj*** of the intermediate tumblers ***T***^{3}*,* and allows the first and intermediate tumblers to fall to their original position. By the same movement, the secondary tumblers **T**^{2} become held in the position given to them by the key, by means of the tooth **t** being pressed into the **several** notches, as shown in the closed state of the lock (**figure 41**).

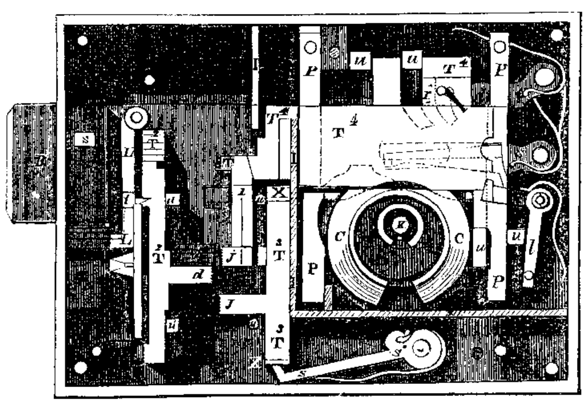

Figure 41 The same with the bolt shot.

Now let us see what results if any attempt be made to open the lock with any arrangement of key but that by which it has been locked. In such case, the tongues **d** will abut against the jaws ***jj*,** preventing the bolt from being withdrawn; and should an

attempt be made to ascertain which tumbler binds and requires to be moved, the intermediate tumbler **T^3** (which receives the pressure), being behind the iron wall **II**, which is fixed completely across the lock, prevents the possibility of its being reached through the keyhole; and the first tumblers **T** are quite detached at the time, thereby making it impossible to ascertain the position of the parts in the inner chamber behind the wall **II**. **K** is the drill-pin, on which the key fits; and **c** is a revolving ring or curtain, which turns round with the key, and prevents the possibility of inspecting the interior of the lock through the keyhole.

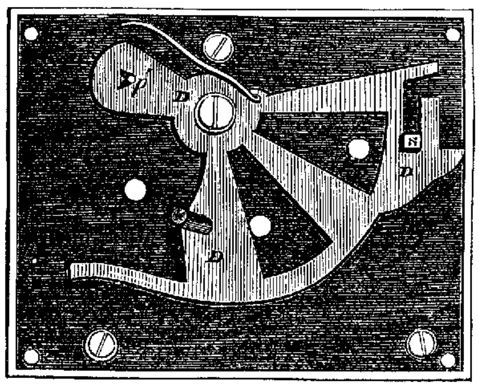

Figure 42 The detector plate of the Parautoptic lock.

Should, however, this ring be turned to bring the opening upwards, a detector-plate **D**, **figure 42**, is immediately carried over the keyhole by the motion of a pin **p^1** upon the auxiliary tumbler **T^4**, which is lifted by the revolution of the ring **c**, thereby effectually closing the keyhole.

As an additional protection, the bolt is held from being unlocked by the stud or stump **s** bearing against the detector plate; and, moreover, the lever **ll** holds the bolt, when locked, until it is released by the tail of the detector-plate pressing the pin **p^1**; **l^1** is a lever which holds the bolt on the upper side, when locked, until it is lifted by the tumblers acting on the pin **p^1**; **x** are separating-plates between the intermediate tumblers **T^3**; **uu**

x are separating-plates between the intermediate tumblers **T**^{3}; **uu** are the studs for preserving the parallel motion of the different tumblers.

Figure 43 Key of the Parautoptic lock.

Figure 44 End view of t

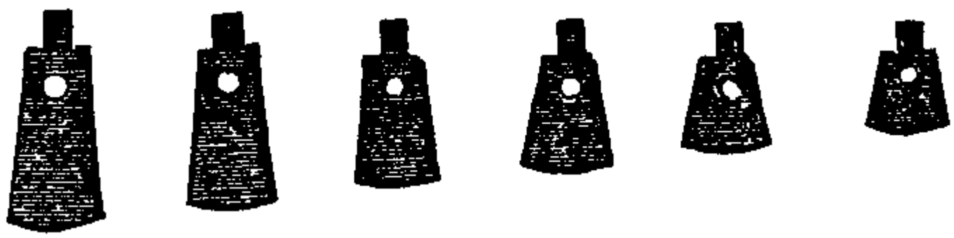

Figure 45 Separate bits of the key.

Figure 43 represents the key in two different forms, or with the bits differently arranged. Either form will lock the lock, but the other will not then unlock it. The end of the key is represented in **figure 44**, showing the screw which fixes the bits in their places. The bits for a six-bitted key are shown separately in **figure 45.**

In 1847 the parautoptic lock was exhibited at Vienna before the National Mechanics' Institute of Lower Austria; and towards the close of the year Mr. Belmont, Consul-General of Austria at New York, placed in the hands of Messrs. Day and Newell a letter, a diploma, and a gold medal, forwarded by the Institute. The letter was from the president of the Institute to Mr. Newell, and was couched in the following terms:

"The Institute of Lower Austria, at its last monthly session, has passed the unanimous resolution to award to you its gold medal, as an acknowledgment of the uncommon superiority of the combination lock of your invention; and this resolution was ratified in its general convention held on the 10th instant."

"Whilst I, as president of this Institute, rejoice in seeing the services which by this invention you have rendered to the locksmith's art thus appreciated and recognized, I transmit to you, enclosed, the said medal, together with the documents relating to it; at the same time availing myself of this opportunity to assure you of my esteem."

"COLLOREDO MANNSFELD

"Vienna, May 31st, 1847."

The diploma and the medal were similar to other honorary distinctions of the same class, and need not be described here; but the report of the special committee may be given, as it expresses the opinions of the Viennese machinists on the relative principles by which safety is sought to be obtained in different kinds of locks.

REPORT

Of a Special Committee on the new Parautoptic Permutation Lock of the American Newell, made known to the Lower Austrian Institute by the Councillor, Professor Reuter, and on the motions relating to it made by the same and accepted by the Institute. Presented at the monthly meeting, April 6th, 1847, by Mr. Paul Sprenger, Aulic Councillor on Public Works, &cc.

GENTLEMEN: --At our last monthly meeting, Mr. Reuter, Aulic Councillor and Secretary of the Institute, directed your attention to a newly invented lock of Mr. Newell, of North America, which was represented as excelling all other changeable combination locks hitherto known, and as being without a rival.

The Special Committee which was entrusted with the examination of this lock, and of the motions made by the said Secretary, and accepted by the Institute, has conferred on me the honor of making you acquainted with the results of its investigations.

The attention of your committee was chiefly occupied with the three questions proposed by the said Aulic Councillor in relation to the lock in question:

First: Whether the idea of Mr. Newell was of any practical value for already existing and still-to-be-imvented combination locks;

Secondly: Whether the idea was of sufficient importance to be published and minutely described in the transactions of the said Institute, and;

Thirdly: Whether the merits of the inventor were of sufficient importance to entitle him to a distinction from the said Institute.

The deliberations on the first question, viz. the newness of the idea, and of its practical value, would of necessity enlist the particular attention of your committee, especially since by far the greater number of its members are by their avocation called upon to be interested in the execution of all kinds of locks.

It is therefore the unanimous opinion of your committee) that the idea Of the American Parautoptic Combination Lock is entirely new and without example.

The combination locks with keys have, with few exceptions, such an arrangement that a determinate number of moveable parts (the so-called combination-parts) must by the turning of the key be raised or lifted into a certain position, if it is desired to project the bolt, or, what is the same thing, to lock it out; consequently these parts, or, as they are technically termed, tumblers, could not be transposed or changed, from the circumstances that the key-bit was one solid piece, with various steps or notches adapted to the several tumblers, and one impression from it destroyed the security of the lock.

In order, however, to add more security to such a combination lock and to make the key, in case it should be lost, or any counterfeit made from a wax impression, useless for an unlawful opening of the lock, another step was taken: the key-bit was made to consist of several bits or moveable parts, in such a manner that the owner of the lock was enabled to change the bits, and to forms as it were, new keys different from the former.

But since the bolt of the lock can only be projected whilst the combination parts or tumblers are in a certain position, which position depends upon the **order** of the bits in the key, it is evident that the owner, when changing the key, must at the same time make a corresponding change in the position of the tumblers in the lock itself, before the lock can be of any use for the newly changed shape of the key, which rendered it troublesome, and impracticable for the purpose designed, from the fact that no positive change could be made in the lock, without taking it from the door and then taking the tumblers out of the case, to change them in a suitable form for the key.

This principle of changing the lock is rarely adhered to, as few men understand the machinery of a lock sufficiently to undertake the task, and this circumstance rendered the lock quite as insecure as the former one described.

Another step toward the perfection of combination locks consisted in this, that the key remains unaltered whilst the combination parts of the lock can, before it is locked, be brought into different positions by means of moveable plates on the frame of the lock. These plates were arranged by hand to certain figures, and depended on the memory for adjustment at each time the bolt was to be locked out or in, the key operating only on the bolt, to move it back and forth when the plates were set in proper positions for the purpose; and should the owner forget the arrangement of the plates, after projecting the bolt, his key is of no use to him, and he must resort to the skill of the locksmith to gain access.

The same case may occur in the far less perfect ring-lock of **Reynier**, which is operated without keys, and is opened by means of the rings being turned in a particular position; on these rings are usually stamped letters which, by introducing some word readily suggested to the memory, thus point out the relative position of the rings.

But although in case of these ring-locks the owner is enabled to produce a change in the rings in such a manner that the opening of the lock can, as it were, only become possible by rightly arranging the altered position of the letters, still this lock of Reynier's does not possess that safety and perfection which could have insured it universal application.

M. Crivelli, formerly professor at Milan, has given a minute description of the imperfection of ring-locks generally, in the annals of the Imperial Royal Polytechnic Institute.

It is the unanimous conviction of your committee that the American Lock of Newell surpasses, in the ingenuity displayed in its construction, all other locks heretofore known, and more especially in this, that the owner can, with the greatest facility, change at pleasure the interior arrangement of his lock to a new and more complex one, at every moment of his life, simply by altering the arrangement of the bits in the key, and this is accomplished without removing the lock or any part of it from its position on the door.

Its operation is as follows: At the closing or locking of the lock, whilst the bolt is projecting, the moveable combination parts assume precisely the position prescribed to them by the key, according to the particular arrangement of its bits at the

time the key is turned.

The combination parts do not consist in one set of tumblers only, such as are found in all other locks, but there are three distinct sets or component parts fitting into each other. When the bolt is projected, it dissolves the mutual connection of the constituent pieces, and carries along with it such as are designedly attached to it, and which assume the particular positions given them by the key in its revolution. These parts are rendered permanent in their given form by means of a lever adapted for the purpose, while the parts not united with the bolt are pressed down by their springs to their original places.

If now the bolt is to be returned again, i.e. if the lock is to be unlocked, then the constituent pieces or tumblers which are in the original state must, by means of the key, be again raised into that position in which they were when the lock was closed, as otherwise the constituent parts attached to the bolt would not lock in with the former, and the bolt could not be returned. Nothing, therefore, but the precise key which had locked the lock can effect the object.

This idea in itself, considered by your committee, is as ingenious as it is new, and is accompanied by a perfection in its execution which reflects the highest honor on Mr. Newell, the inventor and manufacturer of the lock.

The lock is built strong and solid, and the several parts are admirably adapted to the functions which they are designed to perform. The walls of steel or iron which separate the security parts from the tumblers, and the cylinder which revolves with the key, present formidable barriers to all descriptions of pick-locks, and render the lock a most positive and reliable security, The tumblers consist of rolled very smooth steel plates, in which the fire-crust has not been filed away, partly in order that the lock might not need oiling, as all these parts are very smooth, and partly that the combination pieces might not easily rust, a thing the adhering fire-crust is not favorable.

The springs, which by the turning of the key must be raised together with the tumblers, are attached to levers, and press upon the latter at their center of gravity, in consequence of which all crowding towards either side is prevented, and the key can be turned with facility, in spite of the many combination parts which it has to raise; and the springs themselves are by their positions so little galled into action, that their strength

can never be impaired by use.

The lock has also another very complete arrangement in the detector tumbler, which is attached to the cap or covering of the lock. This tumbler, on turning the key either way, closes the keyhole, and not only prevents the use of false instruments in the lock, but detects all attempts at mutilating its interior parts.

This lock is especially useful for locking bank-vaults, magazines, country-houses and iron-safes, in which valuable effects, money, or goods are to be deposited for safe keeping. When it is considered that the bib of the key belonging to this lock can be transferred into every possible form within its limits, and since the construction of the lock admits of every combination of the slides resulting from the changes of the key, therefore the lock in question is, in every respect, deserving of the appellation given to it by the Secretary of the Institute, namely, the Universal Combination Lock; and justly so, when we consider that the ten bits attached to the key admit of three millions of permutations, and upward; consequently forming that number of different kinds of keys and locks.

If we consider further, that we need not be limited to the given bit, but that others can be applied, differing in their dimensions from the former; and again, if we consider that from every system arising from a difference in their relative dimensions, a large number of new keys differing from each other will result, and that this can be effected in a space scarcely occupying a square inch, then we cannot refrain from confessing that the human mind, within this small space, has shown itself to be infinitely great.

After this preliminary and general exposition, your committee can answer the three questions propounded to them the more briefly, as the locks heretofore known have all been noticed.

To question first. On the practical value of the invention of Mr. Newell, your committee were unanimous and positive that the principle on which it is based should be preserved.

To question second. For this reason the committee deemed it desirable that a drawing and description of the American lock in question should be published in the Transactions of the Institute of Lower Austria.

To question third. With regard to the claims of the inventor, Mr. Newell, to an honorary distinction from the Institute of Lower Austria, the committee recommends that he be presented with a Diploma of honorable mention and a Gold Medal.

The members of your committee, consisting mostly of fellow-tradesmen of Mr. Newell, experience great satisfaction in the fact that it has fallen to their lot to vote to their colleague on the other side of the ocean an acknowledgment of his successful ingenuity, and they close the Report with the request that the Institute will transmit to Mr. Newell of New York, in North America, the Diploma and Gold Medal, together with a copy of this Report, according to the motion of the Aulic Councillor and Professor Reuter.

[An exact copy of the original Report as preserved in the archives of the National Mechanics' Institute of Lower Austria.]

DR. SCHWARTZ,

Assistant Secretary of the Institute.

There are other circumstances connected with the American bank lock, in relation to events both in the United States and in England, to which attention will be directed in a subsequent chapter.

The English patent for Messrs. Day and Newell's lock, dated April 15, 1851 runs as follows:

"The object of the present improvements is the constructing of locks in such manner that the interior arrangements, or the combination of the internal moveable parts, may be changed at pleasure according to the form given to, or change made in, the key, without the necessity of arranging the moveable parts of the lock by hand, or removing the lock or any part thereof from the door. In locks constructed on this plan the key may be altered at pleasure; and the act of locking, or throwing out the bolt of the lock, produces the particular arrangement of the internal parts which corresponds to that of the key for the time being."

While the same is locked, this form is retained until the lock is unlocked or the bolt withdrawn, upon which the internal moveable parts return to their original position with reference to each other; but these parts cannot be made to assume or be brought back to their original position, except by a key of the precise form and dimensions as the key by which they were made to assume

such arrangement in the act of locking. The key is changeable at pleasure, and the lock receives a special form in the act of locking according to the key employed, and retains that form until in the act of unlocking by the same key it resumes its original or unlocked state. The lock is again changeable at pleasure, simply by altering the arrangement of the moveable bits of the key; and the key may be changed to any one of the forms within the number of permutations of which the pares are susceptible."

The "claims" put forth under this patent are the following:

1. The constructing, by means of a first and secondary series of slides or tumblers, of a changeable lock, in which the particular form or arrangement of parts of the lock, imparted by the key to the first and secondary series of slides or tumblers, is retained by a cramp-plate.

2. The constructing, by means of a first and secondary series of slides or tumblers, of a changeable lock, in which the peculiar form or arrangement of parts of the lock, imparted by the key, is retained by means of a tooth or teeth, and notches on the secondary series of slides or tumblers.

3. The application to locks of a third or intermediate series of slides or tumblers.

4. The application of a dog with a pin overlapping the slide or tumblers, for the purpose of holding-in the bolt when the lock is locked or unlocked.

5. The application of a dog operated on by the cap or detector-tumbler for holding the bolt.

6. The application of a dog for the purpose of holding the internal slide or tumbler.

7. The application to locks of curtains or rings, turning and working eccentrically to the motion of the key, for preventing access to the internal parts of the lock.

8. The application to locks of a safety-plug or yielding plate, at the back of the chamber formed by such eccentric revolving curtain or ring.

9. The application to locks of a strong metallic wall or plate, for the purpose of separating the safety and other parts of the lock from each other, and preventing access to such parts by means of the keyhole.

10. The application to locks of a cap or detective tumbler, for the purpose of closing the keyhole as the key is turned.

11. The constructing a key by a combination of bits or moveable pieces, with tongues fitted into a groove and held by a screw.

12. The constructing a key having a groove in its shank to receive the detector tumbler.

When the American locks became known in England, Mr. Hobbs undertook the superintendence of their manufacture, and their introduction into the commercial world. Such a lock as that just described must necessarily be a complex piece of mechanism; it is intended for use in the doors of receptacles containing property of great value; and the aim has been to baffle all the methods at present known of picking locks, by a combination of mechanism necessarily elaborate.

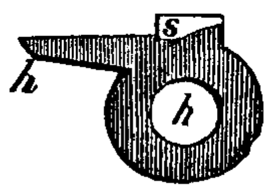

Figure 46 Moveable Stump.

Such a lock must of necessity be costly; but in order to supply the demand for a small lock at moderate price, Mr. Hobbs has introduced what he calls a ***protector lock.*** This is a modification of the ordinary six-tumbler lock. It bears an affinity to the lock of Messrs. Day and Newell, inasmuch as it is an attempt to introduce the same principle of security against picking, while avoiding the complexity of the changeable lock."

The distinction that Mr. Hobbs has made between secure and insecure locks will be understood from the following proposition, viz.

"that whenever the parts of a lock which come in contact with the key are so affected by any pressure applied to the bolt,

or to that portion of the lock by which the bolt is withdrawn, as to indicate the points of resistance to the withdrawal of the bolt, such a lock can be picked."

Figure 47 exhibits the internal mechanism of this new patent lock. It contains the usual contrivances of tumblers and springs, with a key cut into steps to suit the different heights to which the tumblers must be raised. The key is shown separately in **figure 48.**

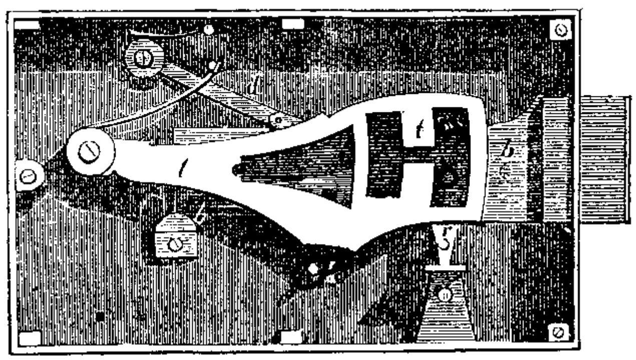

Figure 47 Hobbs's Protector Lock.

But there is a small additional piece of mechanism, in which the ***tumbler*** **stump** shown at **s** in **figures 46** and **47** is attached; which piece is intended to work under or behind the bolt of the lock. In **figure 47, b** is the bolt; **tt** is the front or foremost of the range of six tumblers, each of which has the usual slot and notches.. In other tumbler-locks the stump or stud which moves along these slots is riveted to the bolt, in such manner that, if any pressure be applied in an attempt to withdraw the bolt, the stump becomes pressed against the edges of the tumblers, and bites or binds against them.

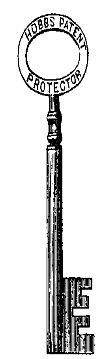

Figure 48

How far their bitting facilitates the picking of a lock will be shown further on; but it will suffice here to say, that the moveable action given to the stump in the Hobbs lock transfers the pressure to another quarter. The stump **s** is riveted to a peculiarly-shaped piece of metal ***h p*** (**figure 46**), the hole in the center of which fits upon a center or pin in a recess formed at the back of the bolt; the piece moves easily on its center, but is prevented from so doing spontaneously by a small binding spring.

The mode in which this small moveable piece takes part in the

action of the lock is as follows: when the proper key is applied in the usual way, the tumblers are all raised to the proper heights for allowing the stump to pass horizontally through the gating; but should there be an attempt made, either by a false key or by any other instrument, to withdraw the bolt before the tumblers are properly raised, the stump becomes an obstacle.

Meeting with an obstruction to its passage, the stump turns the piece to which it is attached on its center and moves the arm of the piece **p** so that it shall come into contact with a stud riveted into the case of the lock; and in this position there is a firm resistance against the withdrawal of the bolt.

The tumblers are at the same moment released from the pressure of the stump. There is a dog or lever **d**, which catches into the top of the bolt, and thereby serves as an additional security against its being forced back. At **k** is the drill-pin on which the pipe of the key works; and **r** is a metal piece on which the tumblers rest when the key is not operating upon them.

Another lock, patented by Mr. Hobbs in 1852, has for its object the absolute closing of the keyhole during the process of locking. The key does not work or turn on its own center but occupies a small cell or chamber in a revolving cylinder, which is turned by a fixed handle. The bit of the moveable key is entirely separable from the shaft or stem, into which it is screwed, and may be detached by turning round a small milled headed thumb-screw. The key is placed in the keyhole in the usual way, but it cannot turn; its circular movement round the stem as an axis is prevented by the internal mechanism of the lock; it is left in the keyhole, and the stem is detached from it by unscrewing.

By turning the handle, the key-bit, which is left in the chamber of the cylinder, is brought into contact with the works of the lock, so as to shoot and withdraw the bolt. This revolution may take place whether the bit of the moveable key occupy its little cell in the plate or not; only with this difference: that if the bit be not in the lock, the plate revolves without acting upon any of the tumblers; but if the bit be in its place, it raises the tumblers in the proper way for shooting or withdrawing the bolt.

It will be understood that there is only one keyhole, namely, that through which the divisible key is inserted; the other handle or fixed key working through a hole in the cover of the

lock only just large enough to receive it, and not being removable from the lock. As soon as the plate turns round so far as to enable the key-bit to act upon the tumblers, the keyhole becomes entirely closed by the plate itself, so that the actual locking is affected at the very time when all access to the interior through the keyhole is cut off.

When the bolt has been shot, the plate comes round to the original position; it uncovers the keyhole and exhibits the key-bit, occupying the little cell into which it had been dropped; the stem is then to be screwed into the bit, and the latter withdrawn.

It is one consequence of this arrangement, that the key has to be screwed and unscrewed when used; but through this arrangement the keyhole becomes a sealed book to one who has not the right key. Nothing can be moved, provided the bit and stem of the key be both left in; but by leaving in the lock the former without the latter, the plate can rotate, the tumblers can be lifted, and the bolt can be shot.

CHAPTER EIGHT: The Lock Controversy: Previous to the date of the Great Exhibition

IT must be evident, even on a cursory glance at the past history of the lock-manufacture, that the prime motive for the introduction of novelties and improvements in construction is the desirability of producing a lock which no one can open without the proper key. From the earliest and simplest lock, down to the latest and most complex, this object has been constantly held in view; and every clear proof or evidence that this object has not been attained has led to the invention of some new contrivance. It has been a succession of struggles to attain security, to show that this security has not been attained, to make a further and more ingenious attempt to detect the weak point in this renewed attempt, and so on.

We need not repeat here, what was stated in an early chapter, that benefit must ultimately result from a candid discussion of this question. When M. Reaumur proposed to explain how the locks

of his day could be picked or opened without the true key, his object was to show to persons who were not locksmiths how far they could depend upon the principle of security offered by locks. But before proceeding on his inquiry, the illustrious naturalist asks, "Ne craindra-t-on pas que nous ne donnions en mime tems des lecons aux voleurs?" And he replies, "Il n'y a pas grande apparence qu'ils viennent les chercher ici, et qutils en aient besoin; ils vent plus grands maltres que nous dans l'art d'ouvrir les Fortes. Apprenons donc l'art d'ouvrir les portes fermees, afin d'apprendre celui de les fermer d'une maniere qui ne laisse rien ou qui laisse peu a craindre."

Before treating of lock controversies and lock violability in England, it will be desirable first to refer to America, where this subject attracted much attention some years earlier than the Great Exhibition; an Exhibition which will always be associated in a remarkable manner with the history of locks.

Soon after the inventions by Dr. Andrews and Mr. Newell, in 1841 (described in a former chapter), the rivalry between the two locks ran high; each lock being "unpickable," according to the estimate of its inventor. Mr. Newell thought the best mode of showing the superiority of his own lock would be by picking that of his competitor; and after several trials, he succeeded in bringing into practical application that system of picking which we may designate the *mechanical,* as contradistinguished from the *arithmetical.*

Mr. Newell not only picked Dr. Andrews' lock, but he wound up the enterprise by picking his own. He was probably the first person who honestly confessed to having picked his own unpickable lock. This discovery led Mr. Newell, as has been noticed in a former page, to the invention of the triple-action or parautoptic lock.

The mechanical principle, as applied to the picking of a tumbler lock, is nearly the same whatever form of construction be made the medium of experiment. When a pressure is applied to the bolt sufficient to unlock it if the tumbler obstructions were removed, the edges of the tumbler bite or bind against the stump of the bolt, so as not to move up and down with such facility as under ordinary circumstances. By carefully trying with a small instrument each tumbler, and moving it until the bite ceases, the gating of that particular tumbler may be brought to the exact position for allowing the stump of the bolt to pass through it.

This violability is observable in the tumbler-locks under very

varied forms of construction. Mr. Newell, after he had picked his own lock, devised a series of complicated wards, to add to the difficulty of reaching the tumblers; but he could not thereby get rid of the importance of this fact, that wherever a key can go, instruments of a suitable size and form could follow: his wards did not render his lock inviolable.

His next contrivance was to notch the abutting parts of the primary and secondary tumblers, or the face of the stump and the ends of the tumblers; but this failed also. Mr. H. C. Jones, of Newark, N. J., added to all this a revolving pipe and curtain, to close as much of the keyhole as possible. But so far were all these precautions from being successful, that a lock provided with all these appendages, and affixed to the door of the United States Treasury at Washington, was picked.

The makers of locks have, each one for himself, contended against such difficulties as were known to them at the time of inventing their locks; and, mortifying as failure may be, it would be cowardly to yield up the enterprise whenever any new difficulty presented itself. Difficulties, in locks as in other matters, are made to be conquered.

To show how numerous are the sources of insecurity which have to be guarded against, to meet the skill often brought to bear upon this lock, we may adduce the reasons which led Mr. Newell to apply a curtain to the keyhole of his lock. Supposing the interior arrangement of the triple set of tumblers, and the metallic shielding wall, to be perfect, still, *if the first set of tumblers can be seen through the keyhole,* the following plan may be put in operation.

The underside of the tumblers may be *smoked,* by inserting a flame through the keyhole; and the key will then leave a distinct mark upon each tumbler the next time it is used, showing where it began to touch each tumbler in lifting it. This may be seen by inserting a small mirror hinged into the lock through the keyhole. There may even be an electric light used from a small portable battery, to illumine the interior of the lock.

By these and other means the exact length of each bit of the key may be determined; and from these data a false key may be made. It is to prevent this inspection of the works, or any other examination of an analogous kind, that the revolving curtain was applied; but, as stated in the last paragraph, even this did not suffice: ingenuity devised a mode of baffling the contrivance of

curtains as well as that of the wards and false notches in the tumblers.

When the parautoptic lock was completed, it was keenly criticized in America, owing to the long discussions respecting the merits of previous locks. In a matter of this kind, where a commercial motive would lead bankers and companies to apply a very severe test to the security of locks and similar fastenings to strong rooms and receptacles, any experiments made with their sanction became important.

Mere letters or certificates emanating from individuals, expressive of opinions concerning a particular lock, would be out of place in a volume relating to locks generally; but it is quite within the limits of the subject, and has indeed become part of the history of locks, to notice experiments and attempts of a more public character. We may therefore introduce a few paragraphs of this description, relating to the career of the American lock in America itself.

The principal bankers at Boston (U. S.) held a meeting to take into consideration measures for testing the security of bank locks. Consequent on this meeting, Messrs. Day and Newell deposited five hundred dollars with the cashier of the State Bank at Boston, to be by him paid to anyone who could pick the parautoptic lock: the trial was to be conducted under the auspices of the bank.

One of the locks was brought to the bank, and was minutely examined by two machinists on two afternoons, after which it was secured to an iron chest, and locked by a committee appointed by the bank. The key was to remain in the hands of the committee during the trial; and it was to be used at their discretion, in unlocking and locking the door, without the knowledge of either of the other parties, provided that in so doing no alteration was made in the combination-parts of the key.

Ten days were allowed to the operators for the examination and the trial; if they succeeded they were to have five hundred dollars; but if they injured the lock they agreed to forfeit two hundred, as a purchase price. At the end of the period the lock remained unopened and uninjured; and the two deposited sums were accordingly returned to the respective parties.

Messrs. Page and Bacon, of St. Louis, had a strong room lock made by one of the chief locksmiths of that city. To test its

security, the proprietors requested Mr. Hobbs to attempt to pick it; he did so, and succeeded. Whereupon the proprietors, having purchased one of the parautoptic locks deemed it no more than fair play to subject this lock to a similar ordeal, an additional zest being given by a reward of five hundred dollars offered by Day and Newell to the successful picker.

The maker of the former lock accepted the challenge; he was allowed to examine the new lock piecemeal, and was then allowed thirty days for his operations in picking. He failed in the enterprise. Of course, in this, as in all similar cases, the operator had no access to the true key.

It follows from the nature of this lock, as noticed in a former chapter, that when the bolt has been shot, if the bits of the key be rearranged in any other form, the look becomes to all intents and purposes a new lock, so far as that key is concerned, and cannot be unlocked unless the key reverts to its original arrangement.

To test this principle, a box with a parautoptic lock was placed in the room of the American Institute in 1845; it was locked; the bits of the key (12 in number) were then rearranged, and the key was placed in the hands of anyone who chose to try to open the lock, with the offer of a reward of five hundred dollars in the event of the lock being opened.

Here, instead of the operator being called upon to devise new pick-lock implements, he had the actual key placed in his hands, modified however in such a way that, though the modifier could restore the original arrangement (provided he had kept some kind of record), the operator had numerous chances against his success. The lock remained unopened notwithstanding this challenge.

We shall have occasion to show presently, that if the number of tumblers (and consequently the number of bits in the key) be small, not exceeding six, for instance, the possession of the *true* key gives any one the power of opening the lock, provided he has time and patience to go through a few hundred changes of the bits of the key; for, as some one arrangement must have been that by which the lock was locked, it must again occur if the user takes care to make *all* the arrangements in turn, and tries the lock after each.

Whether this constitutes picking a lock, each lock-owner will

decide for himself. All that it is at present meant to state is, that *without* access to the true key, the parautoptic lock has not hitherto been opened; and that *with* the true but altered key, the process of opening is possible, but is slow and tedious.

In 1846 the American Institute appointed a committee to examine into the merits of the parautoptic lock. On the 18th of September in that year the Committee made their report, signed by Professor Renwick and Mr. T. W. Harvey, as follows:

"The Committee of the American Institute, to whom was referred the examination of NEWELL'S PARAUTOPTIC BANK Lock, report that they have given the subject referred to them a careful and attentive examination, and have received full and complete explanations from the inventor. They have remarked in the lock a number of important advantages, and, in particular, very great improvements upon the permutation lock formerly submitted by him to the American Institute."

"Thus, while it retains the advantages of the permutation principle, combined with the property that the act of locking sets the slides to the particular arrangement of the bits in the skeleton key, the parts thus set are completely screened from observation, from being reached by false instruments, or from being injured by any violence not sufficient to break the lock to pieces."

"Having in the course of their inquiries examined the different existing modes in which locks may be picked, forced, or opened by false keys, the Committee have come to the conclusion that the parautoptic lock cannot be opened by any of the methods now practiced, unless by a person in possession of the key by which it was locked, in the exact form of combination in which it was used for the purpose, or in the almost impossible case of the bits being adjusted to the skeleton key by accident in that very form. As the chances of such accidental combination range according to the number of moveable bits, from several thousands to several millions to one, the Committee do not conceive that so small a chance of success would ever lead to an attempt to profit by it."

"In conclusion, the Committee feel warranted in expressing the opinion, that unless methods hitherto unknown or imagined should be contrived for the specific object, the lock in question may be considered as affording entire and absolute security."

The latest form that Messrs. Day and Newell have given to their challenge, after the experience of the last few years, is the following:

"First, a Committee of five gentlemen shall be appointed in the following manner: viz. two by the parties proposing to operate, and two by ourselves; and by the four thus appointed a fifth shall be selected."

"In the hands of this Committee shall be placed Two Thousand Dollars, as a reward to the operator if successful in picking the lock by fair means."

"We will place upon the inside of an iron door one of our best bank locks. The operator shall then have the privilege of taking the lock from the door, and have it in his possession for examination; it shall then be returned to the Committee for our inspection, so that we may be assured that it has not been mutilated or injured. The operator shall then, in the presence of ourselves and the Committee, place the lock upon the door in its original position; after which the Committee shall place upon it their seals, so that it cannot be removed or altered without their knowledge. The lock being thus secured to the door, we shall then be allowed to lock it up ourselves, upon any change of which it is susceptible."

"The time for operation to continue thirty days; and if at the end of that time he shall consider that he has made any progress towards picking the said lock, he shall have thirty days more in which to continue operations."

The Austrian report concerning the American lock was given in a former page, to which we may here refer; and then direct attention to England, and to the discussions which have lately been carried on respecting the safety of locks.

It is of course natural that each inventor of a new lock should, while describing the product of his ingenuity, point out what he conceives to be the imperfections of locks which have preceded: use has sanctioned the custom not only with regard to locks, but also in other important matters. Hence there have been many "lock controversies" in England during the last seventy years. We have seen how freely and justly the late Mr. Bramah criticized all the locks that preceded his own; and he was certainly not the man to shrink from criticism in his own case. Twenty years ago the Bramah lock was itself made the subject of criticism.

Mr. Ainger, in his lecture on the subject delivered at the Royal Institution, London, and afterwards in his article "Lock" in the *Encyclopedia Britannica,* thus narrates the circumstances which led to the adoption of the false notches in the Bramah lock as a means of security: "At length (after the original lock had acquired much celebrity,) an advertisement; appeared in the public papers, requesting those who had lost keys of Bramah's locks, not, as had hitherto been done, to break open their doors or drawers, but to apply to the advertiser, who would undertake to save this destructive process by picking. And it appeared that an individual of great dexterity could perform this operation almost with certainty.

The effect of this discovery on the demand for the locks may easily be imagined; but the effect it had in stimulating ingenuity to provide a remedy is one of the best illustrations of the proverb, that necessity is the mother of invention. Within a few days or weeks, Mr. Russell, who was at that time employed in Mr. Bramah's establishment, devised an alteration which at once, and without any expense, entirely overcame the difficulty, and converted the lock into one of perfect security. This contrivance is the most simple and extraordinary that ever effected so important an object; but before we describe it, we will endeavor to explain what has been called the *tentative* process of lock-picking, and which had been so successfully applied to Bramah's locks."

Mr. Ainger illustrates the subject by an engraving, not of an actual lock, but of a hypothetical arrangement of bolts and notches; and he then makes his reasoning apply to the actual process adopted by the picker of the real lock. "A tendency to revolve was given with some force to the barrel; then, by means of a pair of small forceps, the tumblers (sliders) were tried, and it was ascertained which one was most detained by the pressure against the locking-plate. That which offered most resistance was gradually depressed until its notch was felt to hang itself upon the locking-plate; and so on until the whole were depressed in succession, exactly as they would have been depressed simultaneously by the key."

Mr. Ainger then describes the contrivance which, in his judgment, seemed to render any further attempts to pick the Bramah lock hopeless. This consisted in cutting false notches in the sliders; so as to render it impossible for the picker to tell when he has brought a notch to the plane of the locking-plate, whether it is

a true notch, or one of shallower depth, unfitted to admit the movement of the plate."

This is a very interesting statement, for it shows that the mechanical or tentative method of opening was known in England long ago, although very little attention has been since paid to it. In a complex Bramah lock, and in locks on the combination principle, the difficulty of picking is almost insuperable, so long as what may be termed the arithmetical method is adopted. It is perfectly true, as has been so often stated, that the varied combinations in the arrangement of the slides amount to millions and even billions, when the slides are in any degree numerous; and if a person attempt to pick the lock by ringing the changes on all these combinations, it would very likely require the lives of a dozen Methuselahs to bring the enterprise to an end.

But by the mechanical method, sketched so clearly by Mr. Ainger, the exploit puts on a different aspect. The experimenter passes through the keyhole an instrument so arranged as to give a *tendency* in the bolt to withdraw in the wished-for direction; and a pressure produced in the slides by this tendency gives information concerning the state of the slides; and then comes the tentative process on the slides themselves.

Mr. Ainger was quite right in describing the false notches as an admirable addition to the safety of the Bramah lock; but he was not correct in stating that these notches rendered any further attempts on the lock hopeless. The false notches are not so deep as the true; they will permit the barrel to turn partially but not wholly round. But even supposing that the false notch had been hit upon in nearly every slide instead of the true, and that the barrel had been partially turned to the extent which these notches permitted, there would then be a binding action at the false notches different from that in the true, and this would guide the operator in his search for the true notches. It would not add a new principle different from the one before in action, but it would add to the time during which the search would have to be carried on.

We make these remarks in connection with Mr. Ainger's article, which was probably written twenty years ago. We now come to the year 1850.

At the meeting of the Institution of Civil Engineers, when Mr. Chubb's paper was read, many challenges and counter challenges were made, as to the possibility of picking certain locks. Mr.

Chubb described, among others, a lock on the patent of Mr. Davies, which, ingenious though it be, he considers not safe. Captain D. O'Brien differed from Mr. Chubb in this matter; he had had occasion to open from ten to twenty of Davies' cabinet-locks daily, during a period of two years, and he never once observed the locks to be out of order; in fact, they always appeared to afford great security. Mr. Chubb thereupon rejoined, that he was prepared to produce a workman who would pick any number of Davies' cabinet-locks, of different combinations, which he had never seen before, taking only half an hour for each lock.

As another instance, Captain O'Brien stated that, in his capacity as Inspector of Government Prisons, his attention had been much directed to the subject of secure locks; and he produced, among others, specimens of those in use at the Pentonville Prison; though not of first-rate workmanship, he characterized them as being safe, strong, and cheap. They were on Thomas's principle. The locks had been in use eight years, during which period not one had required to be replaced; and any trifling derangements had been made good whilst the prisoners were at exercise. Mr. Chubb, after making his offer concerning Davies's lock, stated that "he was willing to make the same offer with respect to the locks from the Pentonville Prison; and he might state that, in point of security, he considered them absolutely worthless; in proof of which he exhibited one of them, and a common burglar's tool, by which the lock could be opened with the greatest ease.

In respect to Bramah's lock, there was no particular challenge associated with the proceedings of the evening; but incidental observations were made as to the degree of security pertaining to it. Mr. Farey, after passing a high eulogium on the ingenuity of the principle and the beauty of the workmanship, considered it nevertheless objectionable that the sliders should be so completely exposed to view. He then proceeded to make the following observations: "It had been suggested, that a universal false key for Bramah's locks might be made, with the bottoms of its several notches formed by as many small steel sliders, extending beyond the handle of the key, so as to receive pressure from the fingers, for moving each one of the sliders within the lock, with a sliding motion in its own groove, independently of the other. During such sliding motion, a gentle force could be exerted, tending to turn the barrel round.

Under such circumstances, supposing that the motion of the barrel was prevented by any one slider only; that one, having to resist all the turning force, would be felt to slide more stiffly

endways in its groove, and therefore it could be felt when its unlocking notch arrived opposite the steel plate, and left some other slider to begin to resist the turning force.

“Such a circumstance (continues Mr. Farey) presumes a palpable inaccuracy in the radiating correspondence between the notches in the steel plate and the grooves for the sliders in the barrel, which could not happen with Bramah's workmanship.” He further remarked: "Unfortunately, if a Bramah's key fell into dishonest hands, even for a short time, an impression could be easily taken, and a false key as easily made. A turkey-quill, notched into the form of a key, had sufficed to open a Bramah's lock; and an efficient false key could be formed out of a pocket pencil-case. Such facility of fabrication was an invitation to dishonesty; and as an abortive attempt left no trace, the impunity was an encouragement to repeat the attempt until success is attained."

With respect to Chubb's locks, a discussion arose out of a statement made by Mr. Hodge. Mr. Chubb had himself stated it to be a general opinion that a skilful workman, furnished with impressions taken from the true key, in wax or soap, could make a false key to open any lock; and he considered that, in common locks, with the most elaborate wards, but with only one tumbler, as also in Bramah's locks, there was much truth in the notion.

In respect to his own lock, however, with six double acting tumblers, "a false key made ever so carefully from impressions would not be likely to open the lock, for want of exactitude in the lengths of the several steps; and if the key could not be made exact from the impressions, there would be no chance of rectifying it by trial in the lock, on account of the total uncertainty as to which part required alteration."

Mr. Hodge stated that, in America, he had repeatedly seen impressions taken of locks having twelve or fourteen tumblers, in consequence of the bellies of the tumblers, when at rest, coinciding with the form of the key. He also suggested a method of taking an impression of the bellies of the tumblers; but Mr. Chubb, Mr. Farey, Mr. Stephenson, and Mr. Whitworth, all expressed a disbelief that a Chubb's lock could be opened by the means indicated by Mr. Hodge.

Mr. Hodge admitted that he was not aware of any lock actually made by Messrs. Chubb having been picked in America; but that the locks to which he had adverted were such exact imitations, that

he had no doubt of the Chubb lock yielding to similar treatment. He further stated that there were persons in New York who would undertake to pick a real Chubb lock.

CHAPTER NINE: The Lock Controversy: During and since the time of the Great Exhibition

MASTER EXHIBIT LIST

Figure 49 Pipe key
Figure 50 Square eye

WE next come to the remarkable year 1851, which produced so many unexpected results in connection with the industrial display in Hyde Park, and conferred a lasting benefit on the useful arts and manufactures of the United Kingdom, by bringing their products into contrast and competition with those of other nations. It was to be expected that such a trial as this would afford evidences of national failure as well as of success; but probably no one suspected before the trial, that English locks, so celebrated over the greater part of the world for skilful mechanical design, beauty of workmanship, and perfect inviolability, would readily yield to a well-arranged system of lock-picking. Such, however, was the case; and we are bound to admit that Mr. Hobbs, the author of this system, is an engineer of great skill, and with a profound knowledge of the art of the locksmith.

The first step in the celebrated *lock controversy* of 1851 was taken by Mr. Hobbs himself, who declared to a party of scientific men in the Crystal Palace, that all the locks made in this country up to that date admitted of being very easily picked; and in order to explain to these gentlemen the principle upon which this was to be done, Mr. Hobbs picked one of Chubb's patent detector-locks in their presence in a few minutes.

The fairness of this experiment having been called in question by certain persons who were not present at the time when it was made, Mr. Hobbs, on July 21st, 1851, wrote a letter from the American department of the Great Exhibition, to Messrs. Chubb,

simply announcing that an attempt would be made, on the next following day, to pick a lock manufactured by them, and which was at that time on the door of a strong room in a house named by Mr. Hobbs. Messrs. Chubb were invited to be present at the operation; but no member of the firm attended.

What occurred on the day specified may best be given in the words of a letter written by those who witnessed the operation.

London, July 22 1851.

"We the undersigned hereby certify, that we attended, with the permission of Mr. Bell, of No. 34 Great George street, Westminster, an invitation sent to us by A. C. Hobbs, of the City of New York, to witness an attempt to open a lock throwing three bolts and having six tumblers, affixed to the iron door of a strong room or vault, built for the depository of valuable papers, and formerly occupied by the agents of the South-Eastern Railway; that we severally witnessed the operation, which Mr. Hobbs commenced at 35 minutes past 11 O'clock A.M. and opened the lock within 25 minutes. Mr. Hobbs having been requested to lock it again with his instruments, accomplished it in the short space of 7 minutes, without the slightest injury to the lock or door. We minutely examined the lock and door (having previously had the assurance of Mr. Bell that the keys had never been accessible to Mr. Hobbs, he having had permission to examine the keyhole only). We found a plate at the back of the door with the following inscription: 'Chubb's New Patent (No. 261,461), St. Paul's Churchyard, London, Maker to Her Majesty."

This letter was signed with the names and addresses of the following gentlemen—

Mr. Handley
Mr. T. Shanks
Mr. William Marshall
Colonel W. Clifton
Mr. W. Armstead
Mr. Elijah Galloway
Mr. G. R. Porter
Mr. Paul R. Hodge
Mr. F. W. Wenham
Mr. Charles H. Peabody
Mr. A. Shanks

Several of these names are well and publicly known in England and the United States.

This event gave rise to much newspaper controversy; and attempts were made to show that, as this was not a *test* lock, prepared expressly for challenge, the picking proved nothing as regards the finest of the manufacturers' locks. Two circumstances, however, have to be noticed: that the lock was of sufficient commercial importance to be placed on a door enclosing valuable papers, and that the makers had an opportunity to attend and witness, and comment on the trial, if they so chose.

We may here remark, that one of the ingenious contrivances of the Chubb lock, the *detector,* excited some doubt no less than fifteen years ago, as will be seen from the following. The writer of the article "Lock" in Hebert's *Engineers' and Mechanics Encyclopedia,* while speaking with much commendation of Chubb's locks, points out a curious feature, which seems to him to render somewhat doubtful the surety of the *detector* apparatus. "In Barron's and Bramah's locks," he observes, "the picker has no means of knowing whether the tumblers are lifted too high or not; but in Chubb's he has only to put the detector *hors de combat* in the first instance, by a correct thrust from the outside of the door (which might be accurately measured), so as to fix it fast in its place; the detector then becomes a stopper to the undue ascent of the tumblers, and the extent of their range is thereby correctly ascertained. Thus, it appears to us, the *detector* might be converted into a *director* of the means for opening the lock."

Much will depend on the view which is taken of the circumstance just noted. The object of the detector is not to prevent the lock from being picked, but to show that an attempt has been made to pick it; or, at least, to attain a given purpose by an indirect instead of a direct method. But if there be really any truth in the surmise that the detector actually guides a skilful hand in determining how high the tumblers should be raised, the supposed advantage will be purchased at rather a dear rate. As we are here, however, speaking of facts and not of mere opinions, it is proper to say, that the lock opened by Mr. Hobbs had the detector apparatus, but that it was not disturbed by him in picking the lock.

But instead of reiterating opinions, we will state the method by which most of the tumbler-locks made in England up to the date of the Great Exhibition can be opened or picked.

Bearing in mind the principle on which the picking of locks is said to depend, namely, that "**whenever the parts of a lock which**

come in contact with the key are affected by any pressure applied to the bolt, or to that portion of the lock by which the bolt is withdrawn, in such a manner as to indicate the points of resistance to the withdrawal of the bolt, such a lock can be picked," the first step is to produce the requisite pressure.

If the end of the bolt were exposed, this pressure might be applied by some force tending to shoot back the bolt; but as the bolt, whenever it is shot, is buried in the jamb of the door, or otherwise concealed from view, the pressure can in general only be applied through the keyhole. In order, therefore, to apply this pressure, the operator provides himself with an instrument capable of reaching the talon of the bolt, which in the case of the Chubb lock was a pipe-key of the form shown at *a b*, **figure 49**, furnished at the pipe-end with that portion of the bit of the key ***b c*** which moves the bolt (see **figure 32**, where the step which acts on the bolt is called the terminal step). The other end of the pipe-key is made square, as at ***a***, for the purpose of receiving the square eye **e** of the lever ***ef***, **figure 50**, to the further end of which **f** a weight **w** is attached by means of a string **s**.

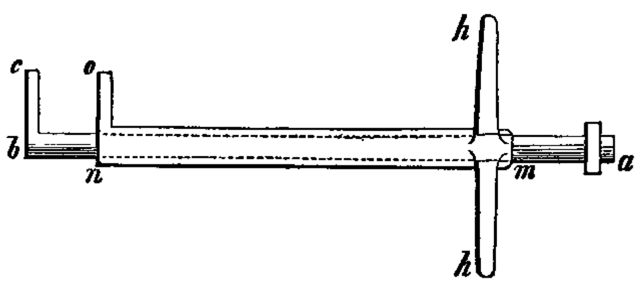

Figure 49

Now it is evident that if this pipe be introduced into the lock as far as it will go, and be turned round as in the act of unlocking, and the lever and weight be attached to the end ***a***, the bit ***b c*** of the pipe-key will maintain a permanent pressure on the bolt, which, if the weight be sufficient, will throw back the bolt as soon as the tumblers are raised to the proper height to allow the stump to pass.

The next step in the operation is to raise the tumblers to the pr
For this purpose a second pipe *mn* is made to slide upon the first

motion, and by means of the cross handle ***h h*** can be turned round or
backwards and forwards on the tube ***a b.*** This tube *m n is* also furnis
single projecting bit or step n o, corresponding with one of the
the Key, **figure 32**, and made of the proper length for entering the k

Now for the operation of opening a tumbler-lock with this simple apparatus. Referring to **figure 31**, it will be evident that if the pipe ***ab,*** **figure 49**, be passed over the pin of the lock and turned round towards the left, and the weight be attached, there will be a tendency in the bolt to shoot back, which tendency will bring the stump **s**, **figure 31**, up against the inner angle or shoulder of one or other of the tumblers, whichever happens to project, however slightly; or, as Mr. Hobbs expresses it, "one or more of the tumblers will bind."

By moving forward the pipe ***m n*** and turning round the bit **n o** in the lock, it is easy to ascertain, by delicate touch, which of the tumblers it is that binds. It may be found that all are free to move except one or two against which the stump is pressing with the force of the weight **w**, **figure 50.** The bit **n o** is therefore brought gently under the bellies of the tumblers which bind, and they are moved slightly upwards until they cease to bind.

As soon as they are set free another tumbler will bind; that is, the bolt will move through a small space, so as to bring the stump into contact with that particular tumbler which now projects; this in its turn is relieved, another tumbler binds and is relieved, and so on until the tumblers are, one by one, raised to the proper height for the stump to pass. When the last binding tumbler is raised to the proper height, the weight **w** being no longer resisted, shoots the bolt back and the work is done.

Now it must be evident that in this operation the detector apparatus need not come into operation. But if, as has been proposed, a detector-spring be added to each tumbler, it may be converted into a friend or a foe according to the use that is made of it. If the tumblers are lifted too *high,* they will be detained or detected in that position, and the operator will have to release them by turning the bit round in the opposite direction before he can begin his work again. The same force,

however, which detains the tumblers when they are lifted too high will obviously detain them when they are lifted only just high enough, and thus the detector-springs would really be of great assistance to the operator in picking such a tumbler-lock.

The apparatus which we have described for picking the tumbler-lock must be varied to suit the form of key employed in opening the lock; but it is not difficult, in the case of most locks, to ascertain this form through the keyhole, without examining the key itself

It is but fair to state in this place, that since the above method of picking tumbler-locks was made known, Mr. Chubb has added a series of teeth and notches to the stump and tumblers; the effect of which would evidently prevent the application of the above method of picking, because any permanent pressure applied to the bolt would send a tooth of the stump into a notch of the tumbler, and prevent all further motion. But recurring to the principle, that whenever the parts of a lock which come in contact with the key indicate the points of resistance when any pressure (whether *permanent or temporary)* is applied in attempting to withdraw the bolt, that lock can be picked, it follows, if this principle be admitted, that although the notches prevent the application of the form of instrument described, yet there is sufficient indication afforded by the pressure to enable a skilful operator, with proper instruments, to form a false key, as was done in the case of the lock referred to earlier.

We now proceed to the second stage in the lock controversy of 1851.

Soon after the picking of the Chubb lock in Great George street, and consequent on the excitement and discussion to which that operation led, a committee, consisting of Mr. G. Rennie, Professor Cowper, and Dr. Black, agreed to superintend the arrangements for a more severe testing of Mr. Hobbs's power to open locks. There had been for many years exhibited in the window of Messrs. Bramah's shop, in Piccadilly, a padlock of great complexity and beauty; to which an announcement was affixed, that a reward of two hundred guineas would be given to any person who should succeed in picking that lock.

This challenge was accepted by Mr. Hobbs; and the committee managed all the arrangements, as arbitrators between Mr. Hobbs on the one side and Messrs. Bramah on the other. The lock was removed to an upper room in Messrs. Bramah's establishment; where

it was placed between two boards, and so fixed and sealed, that no access could be obtained to any part of it except through the keyhole. The room was to be given up to Mr. Hobbs; he was not to be interrupted by the presence or entrance of any other persons; and he was allowed a period of thirty days for opening the lock. If the lock was not picked at the expiration of that period, Mr. Hobbs was to be considered as having failed in his attempt.

There was much negotiation and correspondence before and during Mr. Hobbs's operation on this lock. On July 2, he, with a view to this enterprise, applied for permission to take wax impressions of the keyhole. This permission being given, and the parties having met to discuss the necessary arrangements, an agreement was signed on the 19th, reciting the terms of the challenge and providing that thirty days should be allowed to Mr. Hobbs to effect his enterprise; that the lock should be secured in a certain specified way; and that the key should remain in the possession of Messrs. Bramah, who were to retain the right of using it in the lock when Mr. Hobbs was not at work. Messrs. Bramah subsequently relinquished this last mentioned privilege, in order that the trial might be perfectly fair; and it was agreed that the key should be sealed up during the whole period, beyond the reach either of Mr. Hobbs or Messrs. Bramah; and that the keyhole should be secured by an iron band, sealed, when Mr. Hobbs was not at work. These and other conditions were embodied in the agreement noticed in the last paragraph.

Mr. Hobbs commenced his labors on July 24th. After a few visits to the lock, Messrs. Bramah wished to have the privilege of inspecting it, or else that such an inspection should be made by the arbitrators; and, during a correspondence which arose out of this request, the operations were suspended. Mr. Hobbs resumed his work on August 16. On the 23d, Messrs. Bramah drew the attention of the arbitrators to the challenge, that the reward of two hundred guineas was offered to the artist who should make an instrument that would pick or open the lock; that he was to be paid the money on the production of the instrument; and that, unless some person were present, it was impossible that any one could know that the lock had been opened by the instrument which might be produced. This letter was not allowed by the arbitrators to affect the arrangements made. We may now consistently give the "Report of the Arbitrators."

"Whereas for many years past a padlock has been exhibited in the window of Messrs. Bramah's shop, in Piccadilly, to which was appended a label with these words: 'The artist who can make an

instrument that will pick or open this lock shall receive two hundred guineas the moment it is produced'; and Mr. Hobbs, of America, having obtained permission of Messrs. Bramah to make trial of his skill in opening the said lock, Messrs. Bramah and Mr. Hobbs severally agreed that George Rennie, Esq., F.R.S., of London; and Professor Cowper, of King's College, London; and Dr. Black, of Kentucky; should act as arbitrators between the said parties."

"That the trial should be conducted according to the rules laid down by the arbitrators, and the reward of two hundred guineas be decided by them; in fine, that they should see fair play between the parties."

"On July 23 it was agreed that the lock should be enclosed in a block of wood, and screwed to a door, and the screws sealed, the keyhole and the hasp only being accessible to Mr. Hobbs, and, when he was not operating, the keyhole was to be covered with a band of iron and sealed by Mr. Hobbs, that no other person should have access to the keyhole. The key was also sealed up, and was not to be used until Mr. Hobbs had finished his operations. If Mr. Hobbs succeeded in picking or opening the lock, the key was to be tried; and if it locked and unlocked the padlock, it should be considered as a proof that Mr. Hobbs had not injured the lock, but had fairly picked or opened it, and was entitled to the two hundred guineas."

"On the same day, July 23, Messrs. Bramah gave notice to Mr. Hobbs that the lock was ready for his operations."

"On July 24, Mr. Hobbs commenced his operations; and On August 23, Mr. Hobbs exhibited the *lock opened* to Dr. Black and Professor Cowper (Mr. Rennie being out of town). Dr. Black and Mr. Cowper then called in Mr. Edward Bramah and Mr. Bazalgette, and before them the lock was opened; they [the last-named two gentlemen are of course meant] then withdrew, and Mr. Hobbs locked and unlocked the padlock in presence of Dr. Black and Mr. Cowper."

"Between July 24, and August 23, Mr. Hobbs's operations were for a time suspended; so that the number of days occupied by Mr. Hobbs was sixteen, and the number of hours he was actually in the room with the lock was fifty-one."

"On Friday, August 29, Mr. Hobbs again locked and unlocked the padlock in presence of Mr. G. Rennie, Professor Cowper Dr.

Black, Mr. Edward Bramah, Mr. Bazalgette, and Mr. Abrahart."

"On Saturday, August 30, the key was tried, and the padlock was locked and unlocked with the key, by Professor Cowper, Mr Rennie, and Mr. Gilbertson; thus proving that Mr. Hobbs had fairly picked the lock without injuring it. Mr. Hobbs then formally produced the instruments with which he had opened the lock."

"We are, therefore, unanimously of opinion, that Messrs. Bramah have given Mr. Hobbs a fair opportunity of trying his skill, and that Mr. Hobbs has fairly picked or opened the lock; and we award that Messrs. Bramah and Co. do now pay to Mr. Hobbs the two hundred guineas."

GEORGE RENNIE, *Chairman*. EDWARD COPPER. J. R. BLACK.
Holland Street, Blackfriars, Sept. 2, 1851."

"It may be here stated, in reference to the space of time during which the operations were being conducted, that the actual opening of the lock occurred much earlier, so far as concerned the principle involved, though not in a way to meet the terms of the challenge. On his fifth visit, Mr. Hobbs succeeded in adjusting the slides and moving the barrel, preparatory to withdrawing the bolt; but the instrument with which the barrel was to he turned round, being too slight, slipped, and defeated the operation. Mr. Hobbs had then to readjust the barrel, and to make a new instrument to aid him; this new instrument, when completed, enabled him to open the lock in the space of an hour or two."

"On the same day Messrs. Bramah addressed a letter to the arbitrators, stating the reasons which induced them to think that, though Mr. Hobbs had succeeded in opening the lock, the manner of doing so did not come within the meaning of the challenge originally made by them. The arbitrators, however, were unanimous in their award, and Messrs. Bramah bowed to it."

"In an article written in one of the daily newspapers immediately after the opening of the lock, the following notice was given of the lock and its production: "We were surprised to find that the lock which has made so much noise in the world is a padlock of but 4 inches in width, the body of it 1 ¼″ thick, and its thickness over the boss, 2 ¾″."

"Upon opening the outer case of the lock, the actual barrel enclosing the mechanism was found to be 2 ¼″ in length and 1 ½″

in diameter. The small space in which the works were confined, and its snug, compact appearance was matter of astonishment to all present. The lock and key were made forty years since by the present head of the eminent firm of Messrs. Maudslay and Co., Mr. Maudslay being at that time a workman in the employ of Mr. Bramah."

We may here remark, as indeed has been remarked in former pages, that the Bramah lock is, and will probably continue to be, deservedly celebrated for the amount of mechanism contained in a small space, as adverted to in the last paragraph. The cylindrical form is well calculated for this concentration of power within narrow limits; and the smallness of the key is a great merit.

The objections made by Messrs. Bramah to the award of the committee were embodied in the following letter to Mr. Rennie, dated 9th September:

"DEAR SIR, WE beg to acknowledge your letter of yesterday's date, and will not trouble you to attend here tomorrow, but beg to hand you the 210£ awarded by the arbitrators to Mr. Hobbs. We need scarcely repeat that the decision at which the arbitrators have arrived has surprised us much; and we owe it to ourselves and the public to protest against it. We do so for the following reasons:

1. Because the arbitrators, having been appointed to see fair-play, and that the lock was fairly operated upon, did not, although repeatedly requested in writing to do so, once inspect or allow anyone to witness Mr. Hobbs's operations during the sixteen days he had the sole custody of the lock and was engaged in the work.

2. Because the arbitrators did not once exercise their right of using the key, although repeatedly requested in writing to do so, until after Mr. Hobbs had completed his operations; and then, instead of applying at once to prove that no damage had been done to the lock, allowed him twenty-four hours to repair any that might have occurred.

3. Because the lock being opened by means of a fixed apparatus screwed to the woodwork in which the lock was enclosed for the purpose of experiment (which it is obvious could not have been applied to an iron door without discovery), and the addition of three or four other instruments, the spirit of the challenge has

evidently not been complied with.

4. Because from the course adopted an opportunity of some good scientific results has been taken from us; as neither arbitrators nor anyone else saw the whole or even the most important instruments, by which it is said the lock was picked, actually applied in operation, either before or after the lock was presented open to the arbitrators.

5. Because during the progress of Mr. Hobbs's operations, and several days before their completion, we called the attention of the arbitrators to what we considered the interpretation of the challenge, begging at the same time that they would apply the key and appoint someone to be present during the residue of the experiment; feeling that whatever might be the result in a scientific point of view, the reward could not be awarded.

"We would add, that we think that several points which appear in your minutes should not have been mentioned in your award; more especially that Mr. Hobbs on the 2nd of June took a wax-impression of the lock, and had made, as far as he could, instruments therefrom between that date and the commencement of his operations.

"We are, dear sir, Your obedient servants,
BRAHAM AND CO."

In order that the opinions of Messrs. Bramah and others may be given with as much fairness as possible, on a matter which they could not feel but otherwise than important to them, we may state, that among the letters to which the picking of the Bramah lock gave rise in the public journals, was the following addressed to the *Observer* newspaper on 10th October:

"SIR, This controversy having excited an unusual degree of public attention for some time past, perhaps you will be good enough to allow us to state in your journal, that the lock on which Mr. Hobbs operated had not been taken to pieces for many years, and it was only on examining it (after the award of the committee) that we discovered the startling fact, that in no less than three particulars it is inferior to those we have made for years past. The lock had remained so long in its resting-place in our window that the proposal of Mr. Hobbs somewhat surprised us. After his appearance, however, no alteration could of course be made without our incurring the risk of being charged with preparing a test-lock for the occasion. We were therefore bound

in honor to let the lock remain as Mr. Hobbs found it when he accepted the challenge.

No one inspected his operations during the sixteen days he had the sole custody of the lock and was engaged at the work. We are therefore compelled to advertise another 200 guineas, in order that we may see the lock operated upon and opened, if it be possible; and thus gain such information as would enable us to use means that would defy even the acknowledged skill of our American friends.

We believe the Bramah lock to be impregnable; and we cannot open it ourselves, with the knowledge Mr. Hobbs has given us. We have fitted up the same lock with such improvements as we now use, and some trifling change suggested by the recent trial, and restored it with its challenge to our window. We have not done this in a vain, boasting spirit; on the contrary, we feel it rather hard that, from the way in which the former trial was conducted, we are driven to adopt this course. Had anyone inspected Mr. Hobbs's operations during that trial it would not have been necessary.

"We are, sir, &c.,
BRAMAH AND CO."

Messrs. BRAMAH are well entitled to offer any explanation concerning the relative perfection of the lock in question, and of one that they could now produce with certain improvements in some parts of the working mechanism; but if these improvements do not involve any new invention, patented or otherwise, that is, if the lock be really a carrying out of the contrivances already made public, it is difficult to see why it should not yield to the same treatment as the other. It is true that, shortly after the decision of the arbitrators, Messrs. Bramah exhibited a new lock in their window, and repeated their challenge in the same terms as before, with the single addition, that applications were to be made in writing only. We have reason to know that an application was made, and that the consequence was the withdrawal of the challenge. In respect to the actual contest, however, the character and position of the arbitrators ought surely to hold Mr. Hobbs justified in his proceedings. They were not all Americans (supposing nationality to give a bias in the matter); two were Englishmen, both of distinguished rank in respect to mechanical knowledge; and as Mr. Hobbs was as much bound by their decision as Messrs. Bramah, he was entitled to claim any advantage resulting from a favorable decision.

The following is a description, so far as can be given in words, of the mode in which Mr. Hobbs operated on the Bramah lock. The first point to be attained was to free the sliders from the pressure of the spiral spring; the spring was very powerful, pressing with a force of between 30 and 40 lbs.; and until this was counteracted, the sliders could not be readily moved in their grooves. A thin steel rod, drilled at one end, and having two long projecting teeth, was introduced into the keyhole and pressed against the circular disc between the heads of the sliders; the disc and spring were pressed as far as they would go. In order to retain them in this position, a curved stanchion was screwed into the side of the boards surrounding the lock, and the end brought to press upon the steel rod, a thumb-screw passing through the drilled portion of the instrument and keeping it in its place. The sliders being thus freed from the action of the spring, operations commenced for ascertaining their proper relative positions.

A plain steel needle, with a moderately fine point, was used for pushing in the sliders; while another with a small hook at the end, something like a crochet-needle, was used for drawing them back when pushed too far. By gently feeling along the edge of the slider, the notch was found and adjusted, and its exact position was then accurately measured by means of a thin and narrow plate of brass, the measurements being recorded on the brass for future reference. The operator was thus enabled, by this record, to commence each morning's work at the point where he left off on the previous day. The lock having eighteen sliders, the process of finding the exact position of the notch in each was necessarily slow.

Mr. Hobbs employed a small bent instrument to perform the part of the small lever or bit of the key; with this he kept constantly pressing on the cylinder which moved the bolt. He thus knew that if ever he got the slide-notches into the right place, the cylinder would rotate and the lock open. He could feel the varying resistance to which the sliders were subjected by this tendency of the cylinder to rotate; and he adjusted them one by one until the notch came opposite the steel plate. The false notches added, of course, much to his difficulty; for when he had *partially* rotated the cylinder by means of the false notches, he had to begin again to find out the true ones.

This description accords pretty nearly with that given in a former page; but we reproduce it here to show not merely what might be the process adopted, but what really *has been* done. One

circumstance ought at least to be noted in these transactions: there is no mystery; the method adopted is the result of a process of reasoning candidly and openly explained.

In justice to Messrs. Bramah we thought it our duty to give them an opportunity of stating what improvements they had made in their locks since the date of the Great Exhibition; and accordingly, on the 28th April, 1853, our publisher addressed to Messrs. Bramah a note, stating that a *Rudimentary Treatise on the Construction of Locks* was being prepared, and inviting them to contribute thereto. The following is a copy of their reply:

"124 Piccadilly, May 2nd, 1853.

"SIR, Pressure of business has prevented our sending an earlier reply to your favor of the 28th July.

"The lock on which Mr. Hobbs operated during the Great Exhibition had been made nearly forty years, and when taken to pieces the sliders were found to be in iron, instead of steel; and the keyhole of the lock being three times larger than it ought to have been, enabled the operator to fix down the spring of the lock, and yet leave himself ample space to turn and bend the sliders (being in iron) at pleasure."

"The barrel of the lock in which the sliders act, instead of being whole length from front to back of padlock, was not quite half its proper length; a serious oversight in the workman who put the lock together, as the barrel being short, the sliders were necessarily so, which diminished the number of notches in the sliders full one-half, and to that extent diminished the security of the lock, and increased the facility of the operator."

"We send for your inspection a box of guards, which will show you the barrel and sliders of our Bramah lock. You will observe several notches in each slider, only one of which will turn on the locking-plate, the others being what are termed false, or security ones. These notches being out only the exact width of the locking-plate, require the most perfect accuracy to carry each down to its proper distance."

"In the lock on which Mr. Hobbs operated, in addition to the sliders being so short, and only half the number of security-notches in each, the notch which passed round the locking-plate was found to be cut twice the width it ought to

have been. The whole of these defects have been corrected since the Exhibition."

We are, Sir, yours respectfully,
"BRAMAH and Co." per J. Smyth.
"To John Weale, Esq., 59 High Holborn.'

In the Jury Report of the Great Exhibition, Class XXII., are the following remarks: "On the comparative security afforded by the various locks which have come before the jury, they are not prepared to offer an opinion. They would merely express a doubt whether the circumstance that a lock has been picked under conditions which ordinarily could scarcely ever, if at all be obtained, can be assumed as a test of its insecurity." The conditions here alluded to probably refer to the free access which Messrs. Bramah allowed Mr. Hobbs to have to their lock during a period of thirty days, and we are hence led to infer that the burglar is denied any such facilities. On this point we would refer to the opinion of a high authority.

In a paper "on the History and Construction of Latches and Locks," by Mr. Chubb, read before the Society of Arts, 22d. 1851, the following graphic passage occurs:

"In order to show the absolute necessity of secure locks and safe depositories for property, especially in banking establishments, it may not be out of place to trace the systematic care and great sagacity with which the large burglaries are planned. You will bear in mind that an unsuccessful attempt is seldom made where the booty is of any magnitude. The first-rate 'cracksmen' always know beforehand where to go, when to go, and what they are going for."

"When a 'plant,' as it is termed, is made upon a house or a bank, precise information is gained, if possible, as to the depository of the valuables; and if it is found that the safeguards are too strong in themselves, and that the locks are invulnerable, the affair is quietly dropped. But if otherwise, then no expenditure of time or misapplied ingenuity is spared to gain the desired end."

"The house is constantly watched, the habits of its inmates are observed, their ordinary times of going out and coming in are noted; the confidential servants are bribed or cajoled, and induced to leave the premises when their employers are absent, so that impressions may be taken from the locks, and false keys

made. When all the keys required are made, one or two men who have not been previously initiated are generally called in, and receive their instructions to be ready at a certain hour on the following day to enter the house. A plan of the premises is put into their hands, they are cautioned to step over a certain creaking stair or plank, and the keys of the different doors are given them. The day or evening is chosen when it is known that the inmates will be from home; the servant, taking advantage of their absence, fulfils a long-standing engagement with his new and liberal friends. A signal is given—the two confederates enter—the so-called safe is swept of its contents, all the doors are carefully relocked and not until the bank is opened for business next morning is the robbery discovered."

In an article in *Frazer's Magazine* for November 1852, the following observations were made on the Exhibition Jury Report on Locks: "This jury seems to have consisted of the only persons in England who did not hear of the famous 'lock controversy' of last year; for one can hardly imagine that, if they had heard of a matter of so much consequence to the subject they were appointed to investigate, they would have altogether abstained from saying anything about it."

"They may be excused for not knowing, because very few people did know, fortunately for our safes and strongboxes, that the mode of picking Bramah's and Chubb's locks, by which the transatlantic Hobbs gained so much glory, was suggested and explained in the *Encyclopedia Britannica* nearly twenty years ago. But it does seem very strange that they, or at least their reporter, should not have known, long before the Report finally left his hands, that Hobbs had picked both of those locks, and taught every lock-picker in England how to do it, if he possesses the requisite tools and fingers."

"Of course, however, the reporter did not know it, as nobody could read any newspaper last autumn without knowing it. And this jury did exercise their judgment to the extent of declaring that Hobbs's own lock (under the name of Day and Newell) 'seems to be impregnable.' Notwithstanding all which, they express their inability to 'offer any opinion on the comparative security afforded by the various locks that have come before them.'"

"The only discrimination which they venture to make is, that the keys of Bramah's and Chubb's locks are of convenient size, while Hobbs's is ponderous and bulky, and his lock complicated; and they might have added (without any very painful amount of

investigation), enormously expensive, in consequence of its complication, and probably also more likely, on the same account, to get out of order and stick fast, and so become rather inconveniently impregnable, on the money door of a bank, for instance, than the other two locks, especially Bramah's."

"In relation to the opinion just given, it may be remarked that the American lock has shown no tendencies to get out of Order; if well constructed (and good construction is a *sine qua non* in such mechanism), the parts work into and upon each other with very little friction. In respect to expense, and to the size of the key, a bank-lock is not one in which economy would be much studied, security being the great desideratum."

"No attempt is made to produce a parautoptic lock of small size or for cheap purposes. The lock, therefore, must be judged of with reference to what it undertakes to perform. And this brings us to notice the attempts made in England to pick the parautoptic or American bank-lock."

"The following were the circumstances connected with Mr. Garbutt's attempt to pick the American lock. It is of course known that a challenge was affixed to the American lock in the Great Exhibition, and it was this challenge which Mr. Garbutt accepted. Mr. Garbutt, it may be here observed, was a working locksmith and engineer; he had been entrusted by Messrs. Fox and Henderson with the care and adjustment of the metal check-tables at the pay-places of the Crystal Palace; he had at a previous period been in the employ of Messrs. Bramah."

"We mention these facts only on account of an erroneous rumor at the time that he was an agent of Messrs. Bramah in respect to the acceptance of the American challenge; whereas we believe he acted independently, by and for himself."

"On Sept. 10th, 1851, Mr. A. H. Renton, Mr. E. H. Thomson, and Mr. W. F. Shattuck, the first an engineer, and the other two American exhibitors, were appointed arbitrators to superintend the arrangements, and they met Mr. Garbutt and Mr. Hobbs at the house No. 20 Knightsbridge."

"The following conditions were agreed to: That a Newell lock should be selected, and should be screwed to a wooden box; that Mr. Garbutt should have access only to the keyhole of the lock, through which keyhole all his operations for picking the lock should be conducted; that Mr. Garbutt should have uninterrupted

and exclusive access to the box, between the hours of nine in the morning and nine in the evening for thirty days, beginning on the 11th of September, he having during that time the privilege of introducing one associate, and the arbitrators reserving to themselves the right of inspecting the seals placed by them on the box; that, in order to afford every information concerning the internal arrangement of the lock, the trial-lock should be taken to pieces in presence of all the parties; that it should be examined by Mr. Garbutt; that it should be locked and unlocked with the proper key by him and by Mr. Hobbs; that it should be fastened to a box, and the fastenings sealed by the arbitrators; that the key, when the lock was finally locked, should be sealed up by the arbitrators and delivered to Mr. Hobbs, who would retain it until required by the arbitrators to hand it over to them."

"That at the expiration of the thirty days, or earlier in case either of the success or the abandonment of the attempt, the arbitrators should examine the lock. And, finally, that if Mr. Garbutt should have succeeded in picking the lock (that is, in withdrawing the bolt without injuring the lock), the sum of 200£ should be paid to him by Mr. Hobbs."

"In accordance with the above agreement, Mr. Hobbs produced a parautoptic lock, with ten tumblers marked No. 8560. The key and the lock were examined by Mr. Garbutt. The lock was again put together, affixed to a box, and sealed. Mr. Hobbs set the bits of the key (ten in number) to an arrangement chosen by himself, and the lock was then locked by all parties in succession; the key, after the final locking, being sealed up and returned to Mr. Hobbs. Mr. Hobbs at the same time delivered to Mr. Garbutt a similar but smaller lock, which he was to be allowed to retain during the whole period of the trial, to assist in rendering him familiar with the construction of both locks."

"On the 11th of October, the day on which the prescribed period expired, the arbitrators met at the house in question, when Mr. Garbutt delivered up to them the lock uninjured, but *unopened.* The award of the arbitrators was thereupon given in the following terms: "We therefore hereby certify that Mr. Garbutt having had uninterrupted and exclusive access to the lock during the period of thirty days, and, availing himself of the conditions of the agreement, had every facility for opening the lock that could be obtained without possession of the true key, has delivered up the same into our hands unopened and uninjured; and the said lock has been delivered by us to Mr. Hobbs."

It will of course be understood that it was one condition of this enterprise, that the particular combination of bits in the key wherewith the lock was finally locked should not be seen by Mr. Garbutt. The key was in the first instance tried by Mr. Garbutt and by the members of the committee, and was found to turn readily in the lock; Mr. Hobbs then left the room; and rearranged the bits of the key so as to produce a new combination; he then returned to the room, and locked the lock with the key in its altered form; he allowed all present to feel the key turn freely, and then, without allowing anyone to see the combination, wrapped the key up in paper, in which it was sealed as above described. Whether Mr. Garbutt, or anyone, could have succeeded better by a momentary glance at the arrangement of the key, was not at that moment the question: the terms of the challenge were that he should *not* see it. What are the circumstances likely to occur if the operator really has access to the key (provided the bits are not very numerous) we may shortly explain.

It is necessary to draw a distinction between *picking of a lock* and ringing *the changes on a permutating key;* otherwise some of the late occurrences connected with locks can hardly be understood.

After the reading of a paper by Mr. Hobbs before the Society of Arts, a discussion arose, in which it was stated that the Newell lock had been picked in London. Mr. Hobbs deemed it necessary to refute this statement. The report was circulated in many of the London newspapers; and Mr. Jeremiah Smith, the operator in question, supported it by his own statement. Under these circumstances Mr. Hobbs, on April 2, 1852, addressed a letter to the editor of the *Observer;* of which the following paragraph was intended to point out the distinction above mentioned between "picking" and "ringing the changes."

"Early last autumn I lent to Mr. Potter, of South Molton Street, one of my locks, for the purpose of giving him an opportunity to make himself acquainted with its principle and construction. After he had had the lock in his possession several weeks, a report reached me that one of Mr. Potter's workmen had picked my lock. I immediately called on Mr. Potter to ascertain the fact. Mr. Potter informed me that for the purpose of testing the possibility of opening the lock by means of an impression taken, or a copy being made of the true key, Mr. Smith had made a copy of the key by means of a transfer instrument, which instrument he showed me at the time. After the key was made, it

was tried, and found to lock and unlock the lock as readily as the original key. Mr. Potter then sealed the screws of the lock, changed the combination of the key, and locked it."

"Mr. Smith then took the lock, and with the key that he had made by copying the original, hit the combination, and unlocked it. The lock was of the smallest size, having but six tumblers; the number of changes that could possibly be made were 720. The time occupied by Mr. Smith, according to his own statement, was six hours and fifty-five minutes; this, allowing one minute for each change, would give him time to have made 415 out of the 720 changes before hitting the right one. I asked Mr. Smith why he did not use the original key instead of making a copy? His answer was, that 'he could change the one he made faster, as he did not have to screw the bits in.' Any person will readily understand the difference between ringing the combination of a key and picking a lock."

In other words, the process was this: the operator had the true key, and might have used either this or one which he made from it. This would have sufficed for opening almost any lock ever constructed instantly; but in the American lock he had to find out which of 720 combinations was the right one, and he was employed almost seven hours in doing this. The exploit showed patience, but had little bearing on the practical subject of lock-picking.

In March 1852, Mr. Smith put forth an offer to accept the challenge made by Mr. Hobbs in respect to the Exhibition lock. Mr. Hobbs agreed to the offer, and chose, as arbitrators on his part, Mr. Hensman, Engineer to the Bank of England, and Mr. Appold, inventor of the centrifugal pump which attended so much attention at the Great Exhibition.

Mr. Hobbs requested Mr. Smith to appoint arbitrators on his side also; but this was not done. Mr. Smith, at a meeting held by the four persons named, expressed a wish that an ordinary commercial lock should be the one experimented on, instead of the more complicated test-lock which had been at the Great Exhibition.

This was a departure from the terms of the original challenge; but Mr. Hobbs waived his objection on this point, and offered to substitute a bank-lock with ten tumblers for the Exhibition lock with fifteen, the former being similar in construction but less complex. Another meeting was agreed upon, but Mr. Smith did not attend; and the matter was, by himself, brought to a sudden

termination.

To show the effect of difference in the number of tumblers and key-bits, we may state that, while, at a minute per change, it would take twelve hours to go through all the combinations with a six-bitted key, it would require seven years with a ten-bitted, and 2,500,000 years with a fifteen-bitted key! So much for power of combination, in the arithmetical mode of picking.

We now proceed to notice the violability of sundry minor locks. It might at first appear that the *letter-lock is* exceedingly difficult to pick; and so it unquestionably is, as long as we merely attend to the chance medley trials by turning the rings round and round until we happen to hit upon the right combination. But there is another mode of solving the riddle, mechanical rather than arithmetical. A piece of common wire, bent in the form of the shackle, is put in between the ends of the lock; the spring or elasticity of the wire tends to force the ends apart; this causes the pins or studs on the rod to press against the inner edges of the rings.

By trying all the rings in succession, some one of them will be found to bind or cling more than the others; this is turned round until the cessation of the bind shows that the notch in the ring has been brought into its right position relatively to the pin on the rod. Then another ring which binds more than the rest is treated in a similar way; until at length all the rings seem to be so far liberated as to indicate that the notches are in the right positions. In the dial-lock, similarly, when a pressure has been brought to bear upon the bolt in the right direction, a trial of the pointers will soon bring the notch in each wheel to the required position.

Some short time after the events in London connected with the lock controversy, Mr. William Brown of Liverpool described the letter-lock noticed in a former page, characterizing it as a lock which he believed no one could pick. An incident in the history of this lock was thus narrated in one of the Liverpool newspapers. "Mr. Hobbs was taken by Mr. Milner to the office of Messrs. Brown, Shipley, and Co., and shown this lock. The safe-door was closed and locked by the cashier at Mr. Brown's request; and then Mr. Hobbs began to illustrate his views of the construction of the lock by manipulation and explanation, with which the subject of them appeared to sympathize so entirely and promptly that the door opened in a few minutes."

In respect to the picking of the Egyptian lock, the main difficulty would be in obtaining any false key that would correspond with the pins of the lock; but this might be accomplished in a way analogous to that which is practiced in many other cases. If a small piece of wax be laid on a blank key, the key inserted into the lock, and the blank pressed upwards against the pin-holes, there would be left an impression of those holes on the wax; this impression would furnish a guide to the fabrication of a false key. There is also very little difficulty in picking this lock by one of the ordinary instruments.

For the Yale lock, combining something like the pin-action of the Egyptian with the cylinder-action of the Bramah locks, the picking requires the use of an instrument that will fit between two of the pins, and to the outer end of which is attached a lever and weight; by this means a pressure is exerted upon the cylinder in the right direction for it to turn, and the pins are made to bind.

Then, with another instrument, the pins are felt, and each one moved until it seems to be relieved from the bind: this indicates that the joint in the pin coincides with the joint between the two cylinders; and when all have been similarly treated, the weight acting on the inner cylinder will turn it. It is evident that this method is the same in principle as the one applicable to the Bramah lock.

CHAPTER TEN: Effects of the Great Exhibition of 1851 in Improving English Locks

MASTER EXHIBIT LIST

Parnell's Lock
Denison's Lock
Chubb Barrel and curtain lock
Chubb tumbler-bolt lock
Chubb bank-lock

Aubin's lock
Hobbs Protector lock
Saxby lock
Yale lock

WE have now to refer to the effects of the lock controversy. It was no doubt annoying to be told, on good authority, that the machines on which we so much prided ourselves were wrong in principle; and that our locks, in order to afford the degree of security which are expected of such contrivances, must be reconstructed. The grumbling with which the first part of this proposition was received would alone have sufficed to lead to a suspicion of its truth, if the large number of new locks that have actually appeared had not confirmed it. Whether the second part of the proposition has been fairly carried out, is a point that must now be considered.

One of the first locks produced during or immediately after the lock controversy was Mr. Parnell's, to which the bold term *of patent defiance lock is* attached. This lock is said to depend for its security on a mode of arrangement which may best be described in the inventor's own words:

"Viewing the lock from its exterior, it presents nothing remarkable; but, upon removing the plate, it will be seen that all possible access to the mechanism with false or surreptitious keys is effectually prevented by a solid cylinder of *hardened [?] brass,* with protecting wards extending the whole depth of the lock, and having in the center the aperture for the key, which fits to a mathematical nicety so exact as to preclude the possibility of any second instrument being used to open it."

"This protecting cylinder must revolve with the key to get to the works; and the moment it passes from the keyhole in going round to lock or unlock, the solid portion moves into its place, and so completely closes that aperture that the point of a pin, or a fine steel-pen, has failed to be inserted between it and the outer plate or cap, to say nothing of the utter hopelessness of perforating the metal."

"The cylinder or protecting cap, though it revolves by the action of the key somewhat in the same way as the cylinder of the Bramah lock, appears to be intended rather for closing or protecting the keyhole than for governing the movements of the bolt."

"The internal arrangements of the lock are as follow: Supposing the bolt to be shot, and to be about to be unlocked, the key, by the time it has made about one-third of a rotation, meets with a forcible resistance in the shape of an upright spring-bolt or detector of strong steel acting on the revolving cylinder. The key passes this detector, and arrives at the levers or tumblers. In the bolt-stud which works in the slot of these tumblers there is a small deep serrated notch on one side, corresponding to similar notches on each of the tumblers; if, therefore, the bolt be forced, these notches would lock into each other in a similar manner to the catch on a ship's windlass or a hoisting crane."

"There is also a double-action tumbler-bolt, so adjusted, that if any of the tumblers be over-lifted, this little appendage becomes thrust down at one end into the bolt of the lock, where it wedges all fast until the tumblers become properly readjusted. The double-action tumbler-bolt also falls into the lock-bolt when the latter is locked or shut, thereby imparting an additional strength to the lock."

"The key has a power of expansion or enlargement while turning in the lock; it meets with an eccentric plate which draws out the bits somewhat; so that, at the moment of acting on the tumblers, they protrude farther from the pipe of the key than when the key entered the keyhole. The key is, in fact, larger when in than when out of the lock. There is connected with the works of the lock a detention-cap so formed that, in the event of a false key being used, a powerful bolt instantly locks into the revolving cylinder, and holds fast the surreptitious instrument."

Such is, in substance, the account which Mr. Parnell has given of his own lock. It must, however, be stated, that the points of security or novelty claimed by Mr. Parnell for his lock were patented by previous inventors. The revolving cylinder or curtain was claimed by Mitchell and Lawton in the patent of 7th March, 1815, as noticed earlier in this book. The expanding key-bit was claimed by Mr. Machin of Wolverhampton in 1827, and by Mr. Mackinnon; while the serrated notches in the tumbler were used by many lock-makers long before the date of Mr. Parnell's patent. The detention-cap for catching and holding a false key when put into the lock was also patented by Mitchell and Lawton.

We come now to notice a lock lately invented by Mr. E. B. Denison (the author of the *Rudimentary Treatise on Clocks* in this series), which has the merit of combining considerable novelty in

construction with security. After the details given in the two preceding chapters, it will certainly be no small praise when we express our conviction that in the present state of the art of lock-picking, this lock may be considered as secure. Mr. Denison has furnished us with a description of his lock, which we insert almost in his own words.

Mr. Denison claims for this lock the following advantages:

1. **That a very large and strong lock on this construction only requires a very small key.**
2. **That no key is required to lock it, although it is free from the inconvenience pertaining to spring-locks, viz. that the door cannot be shut without locking itself. Moreover this lock is more secure than any spring-lock can be.**
3. **That it cannot get out of order from the usual causes of the tumblers sticking together or their springs breaking, inasmuch as the action of the tumblers does not depend on anything but the key and the handle, and there are no tumbler-springs.**
4. **That for the same reason, the parts of this lock do not require any polishing or delicacy of execution.**
5. **That the keyhole being completely closed by a curtain, except when the key is in, the lock is protected from the effects of the atmosphere and dust entering at the keyhole.**
6. **That this lock is secure against any known mode of picking; the smallness of the keyhole prevents the insertion of any instrument strong enough to open the lock by violence.**
7. **That this lock, from the simplicity of its construction, admits of being made at small cost.**

These objects are accomplished as follows:

In **the large sized** locks, such as would be used for safes and large doors, the tumblers **T. figure 51**, are made of pieces of hoop-iron, six or seven inches long and twelve inch wide: these tumblers are supported by and turn on a pin **a**, placed at about the middle of their length; so that being balanced on the pin, or nearly so, and having their separating plates **p** between them which cannot turn, the tumblers will stand in any position indifferently; and in order to secure sufficient friction to keep them steady, one or more of the separating plates **P** is bent a

little, so as to act as a spring when the cap of the lock is screwed down.

The lock is shown in **figure 51** as locked, the bolt **B** having been shot by the fantailed piece **f** on the handle, and the tumblers sent down, so that the stump s cannot enter their jaws by the other piece of the handle; and it is evident that the handle cannot draw the bolt back again until the tumblers have all been raised by the key to the proper position to allow the stump s to enter their jaws.

It will be observed that in the position shown in the figure, the stump does not touch the tumblers; and consequently, so long as the bolt is kept in the position represented, no pressure of the stump against the tumblers can be felt, although by means of a false key or pick-lock the tumblers can be raised to any height.

No implement, however, can be pushed into the keyhole without first pressing in the curtain **x**, which is held up against the cap of the lock by the two spiral springs **c c** on each side of the keyhole; and at the back of the curtain there is a square plug **p** which goes through a hole in the back of the lock, and has a notch in it through which the bolt can pass when the curtain is up, closing the keyhole, but at no other time.

In other words, the act of pushing in the key sends down the curtain plug, the effect of which is to hold the bolt fast in the position in which the stump cannot be made to touch the tumblers. If the proper key is used and turned about half round to the right, it will bring the tumblers to the proper height for the stump to pass. The key is then taken out; for so long as it is in the lock, the bolt cannot be moved; and then turning the handle to the right, the bolt is drawn and the door opened.

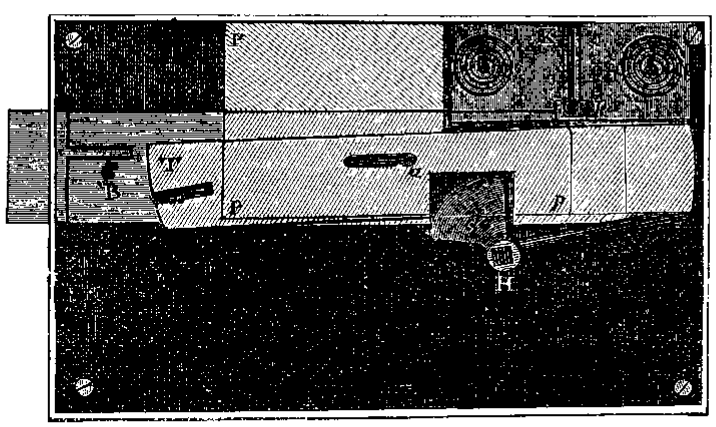

Figure 51 Mr. Denison's large lock.

The handle **H** should be so made, that as soon as the fantailed piece has sent the bolt just clear of the tumblers, the other arm to the right of **H** may begin to move the tumblers; but the fantail need not send the stump above one-sixteenth of an inch beyond the tumblers; and the curtain-plug and bolt must be so adjusted that the curtain cannot be pushed in until the bolt is so far out that the stump is this one-sixteenth of an inch beyond the tumblers.

The curtain **K** need only be a thin piece of steel, and the bolt **B** must be thick enough for the curtain to go down just to the level of the thin plate **P** between the bolt and the first tumbler **T.** The curtain-plug **p** is made as long as the keyhole and rather broader, and of the shape represented, partly for the sake of steadiness in pushing in the curtain, and also for more completely protecting the keyhole; for if an attempt be made to pick the lock by drilling into the keyhole, the drill will pass into the inside of the door and not into the inside of the lock.

It is true that iron safes have been made for some years in which any number of large bolts are shot by a handle and then locked by a very small key. But in such locks the key must be used in locking, and this leads to certain objections, viz. the key must occasionally at least be confided to some person whose duty it is to lock up the safe after the owner has left the place; there is also the temptation to leave the key in the lock, since it will be wanted in locking up; and thus there is the danger of some dishonest person taking an impression of the key. Besides this, the real strength and security of such safes is only that due to the small lock which locks into the main bolt; whereas in Mr. Denison's lock the security and strength are those due to the lock itself, with its large and strong tumblers, and other provisions peculiar to its construction; and the key for a lock of the largest size, which was lately exhibited at the Society of Arts by Messrs. S. Mordan and Co., the makers, only weighs a little more than a quarter of an ounce. It may be mentioned that for large, locks the key may be solid, although in the small ones it is more convenient to have a pipe-key, on account of the different construction of the curtain.

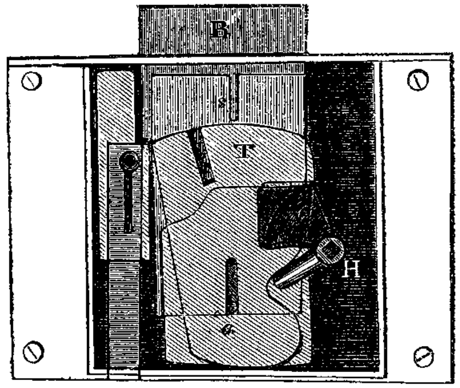

Figure 52 Mr. Denison's small lock.

The arrangement of the small lock for drawers, etc. is somewhat different from that of the large ones, and will be understood by referring to **figure 52**. The action of the handle **h** on the bolt **B** and on the tumblers **T** is sufficiently clear from the figure. The curtain in this case has no plug, but is only a flat plate held up by a thin spring behind it, and moving up and down on the drill-pin of the key, and kept from turning by having one edge against the side of the lock.

The bolt has a kind of second stump, only coming up so high as to be able just to pass under the corner of the curtain when it is up, but not able to pass when the curtain is at all pressed down by anything inserted in the keyhole. In a drawer lock the key has only to be turned a quarter round in order to raise the tumblers. In small locks, the friction of the tumbler-plates is quite enough to keep them in any position, without putting the pin in the middle so as to balance them, as in large locks with heavy tumblers.

In the making of these locks the key must be made first, with proper provisions to prevent the repetition of the same pattern; a kind of pattern or model for locks of each size should be made; the tumblers put on the pin with plates of the intended thickness between, and when raised by the key to the proper height they should be clamped down; and the jaws for the stump of the bolt may then be cut by a circular saw moving in a slit in the model corresponding to the place of the stump. The tumblers for large locks may be cut off from a strip of hoop-iron to the proper lengths by a stamping cutter, giving them the proper circular end, and a punch might at the same time make the pin-hole in the middle. The tumblers for small locks should be stamped out of sheet brass or iron.

It will thus be evident that from the general simplicity of construction, and the small amount of finish required in the working parts, this lock can be made at small cost. We may also add that this lock is as creditable to the public spirit as to the mechanical skill of the inventor; for the lock is not patented, patents being, in Mr. Denison's estimation, obstructions to the progress of science.

The next result of the "lock controversy" which we have to notice is the production of not less than three improved locks by Messrs. Chubb. We thought it our duty to invite the attention of this celebrated firm to the preparation of this *Rudimentary Treatise,* and in answer to the application of our publisher we received the following communication from Messrs. Chubb, which we insert verbatim:

"It will not be necessary to describe the lock as originally made, as a description of it will be found in Mr. Chubb's paper read before the Institution of Civil Engineers."

Lock No. 1. The first of the improvements introduced consists of a barrel, to which a circular curtain is attached, revolving round the drill-pin in the lock; so that if any instrument is introduced to attempt to pick it, the curtain immediately closes up the keyhole, and prevents the introduction of any auxiliary instruments, there being several required in action at once to produce any effect.

"If by any means these several instruments can be introduced simultaneously, the barrel keeps them all confined in a very small space, preventing their expansion, and renders it impossible to work them independently of each other; therefore they are of no avail, being incapable of acting as more than a single pick, which is perfectly useless. The barrel and curtain have each been previously used *separately* in locks, but until patented by Mr. De la Fons in 1846, they had not been used *in combination.* Neither of them, used separately, is of much use, but when combined they afford a very great security."

Locks have been, and still are shown, containing either the barrel or curtain *singly,* and as these have been picked, it has been asserted that the improvement now introduced in Chubb's lock is equally insecure; but a slight examination of the difference in their construction will prove the contrary. Mr. Chubb has purchased the patent-right of this part of Mr. De la Fons'

invention, and applies it to all his locks.

Lock No. 2. The next improvement, recently patented by Mr. Chubb, is based upon the assumption that there may be a possibility of overcoming the security of the barrel and curtain as already described (although this assumption is not in the slightest degree admitted), and consists in applying what is called a 'tumbler-bolt,' working on a hinge connected with the main bolt. The web of the key does not in any case touch the main bolt in unlocking, but acts only on the tumbler-bolt.

All the tumblers must first be lifted, each to its proper position, before the tumbler-bolt will act. Should any pressure be applied to either bolt before the tumblers are all at their exact position, the effect would be to throw the bolts out of gear, and thus effectually to stop the stump of the main bolt from passing through the racks of the tumblers. None of the many plans of picking which have been suggested, such as smoked key-blanks, thin key-bits, etc., would be of the least avail against a lock made on this principle. Different kinds of detectors may be applied to these locks.

It is submitted that this lock, retaining all the simplicity and durability which have distinguished Chubb's lock for so many years, and combining with them these important improvements, affords a complete security against all surreptitious attempts of any nature. Locks on the same principle are being made on the permutation plan, with any number of tumblers, and any number of changes in combination that may be desired.

It has been suggested that the 'detector,' instead of giving additional security to Chubb's lock, affords a partial guidance to a person attempting to pick it. This objection holds good to a certain extent in these locks as originally made, in which all the tumblers had an *equal* bearing against the detector stump; but in the locks as now constructed this objection is entirely obviated, by giving the tumblers an *unequal* bearing, whereby, if an operator feels the obstruction of the detector stump, he cannot tell whether the tumbler which he is lifting is raised too high, or not high enough.

"LOCK No. 3. For banks, Mr. Chubb has introduced what he particularly calls his 'bank lock.' It contains a barrel with a series of curtains. While the keyhole is open, all access to the tumblers from the keyhole is completely cut off by two sliding pieces of solid metal, which fit closely on either side of the

barrel. These pieces are acted upon by an eccentric motion, so that when the key is applied to the lock, and turned in it, the keyhole is shut up by the revolution of the curtains, and then only do the sliding pieces of metal move aside to allow the key to act upon the tumblers."

"These pieces return to their position when the key has passed; therefore, while the key is lifting the tumblers, all communication is cut off from the exterior of the lock by these sliding pieces and the series of curtains. The bolt is made in two pieces, the main bolt never being in contact with the key, which acts only on the talon bolt, and by it transmits the motion to the main bolt."

"After the action of locking, the talon-bolt is partly repelled, and a lever or 'dog' connected with it locks into a series of combinations arranged upon the front parts of the tumblers, and holds them securely down, so that none of them can be lifted in the least degree until the talon-bolt is thrown forward to release them. If, therefore, any pressure be applied to this talon-bolt to endeavor by its help to ascertain the combinations of the tumblers, it will only the more tightly lock them down, and render the attempt ineffectual."

"By another contrivance it is rendered impracticable to move a pick or picks round in the lock more than a small distance, unless the tumblers could previously be all lifted to their right positions, which can only be done by the right key. Should one or more of the tumblers be surreptitiously raised by any possible means, they cannot be detained in this uplifted position, for the action of turning back the pick to try to raise another tumbler sets in motion a lever which allows the tumblers already raised to drop to their former position, leaving the operator just as far from the attainment of his object as at the outset."

Such is the statement with which Messrs. Chubb have favored us respecting their three new locks. We are willing to admit the enterprising spirit which has led to their production, and the ingenuity which has been bestowed on their construction; but whether they mark a step in advance in the art of lock-making may perhaps admit of doubt.

With respect to the lock No. 1, we would remark, that locks with the barrel and curtain combined were made by Mr. Aubin of Wolverhampton in 1833, and that a specimen of such a lock was exhibited on his stand of locks in the Great Exhibition. Locks

with the combined barrel and curtain were also made and sold by Mr. Jones of Newark, N.J.

With respect to the lock No. 2, the object of the *tumbler-bolt is* evidently intended to produce the same effect as the *moveable stump* in Mr. Hobbs's protector-lock, **figure 47**; but with greater complexity in the construction, there is less efficiency in the action of this part of Mr. Chubb's lock as compared with that of Mr. Hobbs, inasmuch as a pressure of the stump against the tumblers, corresponding with the strength of the spring which holds the bolt in its place, can always be produced, thereby giving friction, and affording indication as to which tumbler it is that is in tight contact with the stump.

With respect to the barrel and curtains of lock No. 3, and all similar contrivances, the object of which is said to be to prevent the entrance into the keyhole of all instruments except the proper key, we would offer the self-evident remark, that the same aperture which admits the key will also admit some other instrument. In the case of Mr. Chubb's "bank lock," it may be questioned whether the revolving curtain, etc. give it any advantage over the other locks already referred to which are furnished with similar contrivances.

The effect of the *talon-bolt* in this lock appears to be the same as that of the false notches, namely, to hold the tumblers in the position in which they were placed when the pressure was applied. Hence, a pressure applied to the talon-bolt affects the parts which come in contact with the key in the act of locking and unlocking; and this circumstance brings the lock under the application of the principle stated earlier, and thus, if this principle be admitted, may render the security of the lock somewhat questionable.

Various other locks have been brought out since the date of the "lock controversy" in the year 1851. We would gladly notice them all, did they show novelty of design and mark an advance in the art of the locksmith. We must, however, admire the ingenuity with which Mr. Hobbs's moveable stump has been more or less adopted; but in the attempts to imitate it the objection has not been removed, that it is possible to produce on the tumblers a pressure or friction equal to the strength of the spring which holds the tumblers down.

There is, however, a lock which has lately been introduced to the public, which calls for special notice, on account of the high

honors which have been bestowed upon it. We refer to the prize lock of the Society of Arts, London, the invention of Mr. H. J. Saxby of Sheerness, who has received the Society's medal and the sum of ten guineas as the reward of his ingenuity.

The interior of this lock consists of a cylinder with four pins or slides radiating from the center and pressed into the keyhole by means of spiral springs. The pins project beyond the periphery of the wheel or cylinder, and into slots in a ring that is affixed to the case of the lock, thereby preventing the cylinder from being turned. On each pin is a notch, so placed that when the proper key is inserted into the keyhole, the notches on the several pins will be brought into a position such as will allow the cylinder to turn. The turning of the cylinder in this, as in the Bramah lock, shoots the bolt.

A lock on precisely the same principle, but more secure in its construction, was described by Mr. Hobbs in a paper read by him before the Society of Arts in January 1852, when diagrams illustrative of the same were exhibited. This paper was not reported at any length in the journal of the Society's proceedings; but the same paper was read by Mr. Hobbs, March 1, 1852, before the Liverpool Polytechnic Society, and a full report thereof, and a description of the lock in question, is given in the "Transactions" of that Society, from September 1849 to December, 1852 (8vo, Liverpool 1853). This lock is no other than the Yale lock already noticed in this text, and is thus described at page 196 of the " Transactions:"

"Another description of cylinder-lock was invented, a few years since, by a Mr. Yale of the State of New York, U.S.A."

"The Yale lock has two cylinders, one working within the other; and they are held together by a series of pins reaching through the cylinders into the keyhole, which is in the center. On the back of the inner cylinder is a pin that fits into a slot in the bolt, and moves it as the cylinder is turned. The pins that hold the cylinders together and prevent the inner one from turning are cut in two at different lengths. The key is so made, that by inserting it into the keyhole the pins are moved, so that the joint in the pins meets the joint between the cylinders, and allows the inner one to be turned. But, as with the slides of the Bramah lock, should any one of the pins be pushed too far, the cylinder is held quite as firmly as though it had not been touched. Some of these locks have been made with as many as forty pins; and to a person unacquainted with the principles on which

locks are picked, they would seem to present an insurmountable barrier."

"**Figure 1** represents the case of the lock containing the bolt **A**, having a groove **B**, to receive the pin c on the cylinder. **Figure 2** shows the cap or top-plate of the lock, and the cylinders; **D D** is the outer cylinder, that is stationary, being fastened to the plate; **EE** the inner or moving cylinder; **FF** the four rows of pins, being cut in two at different lengths, and reaching through the cylinders into the keyhole; **G G** are the springs that press the pins to their places; **c** the pin that fits into the groove and moves the bolt. **Figure 3** is an end view of the key, showing four grooves. **Figure 4** is a side view, showing the irregular surface of the grooves by which the pins are adjusted."

"For the purpose of picking the lock, an instrument is made that will fit between two of the pins; to that is attached a lever and weight, thereby getting a pressure on the cylinder and causing the pins to bind; then with another instrument the pins are felt, and as they are found to bind, they are pressed in until they are relieved (as they will be when the joint comes to the right place), thereby easily opening the lock. There is a great similarity in the operation and security of this and the lock manufactured by Mr. Cotterill of Birmingham."

In the *Society of Arts Journal* for the 24th June, 1853, is a letter from Mr. Hobbs on the subject of the prize lock, which it appears, he picked, "in the presence of parties connected with the Society, in the short space of three minutes."

CHAPTER ELEVEN: The Lock and Key Manufacture

MASTER EXHIBIT LIST

THE manufacture of locks and keys, considered as a department of working in iron, is one that requires, and indeed admits of, very little description. The hammer, the file, the drill, the fly-press, are the chief instruments employed; the iron itself being brought to something like the desired state and form by rolling or casting, or both. But the manufacture is interesting in its social features, in its relation to the persons employed and the buildings occupied.

One by one, several departments of industry have progressed from the *handicraft* to the *factory* system, from that system in which a man and a few apprentices work in a small shop in the lockmaker's garret or kitchen, to that in which organization is maintained among twenty or fifty or a hundred men. Locks have scarcely yet passed out of the first stage, but there is no good reason whatever why they should so remain; there are as many reasons for progress in this as in other arts, and indications are not wanting that some such progress will be made.

So far as England is concerned, the neighborhood of Wolverhampton is the great storehouse whence locks are obtained. Eminent lock-makers reside in London and in other principal towns; but Wolverhampton is regarded by all as the center of the trade. This is not a modern localization, for we have information respecting the locks of Wolverhampton a century and a quarter ago. Among the Harleian Manuscripts is an account of "The Voyage of Don Manuel Gonzales (late merchant), of the City of Lisbon in Portugal, to Great Britain: containing an Historical, Geographical, Topographical, Political, and Ecclesiastical Account of England and Scotland; with a Curious Collection of things particularly rare, both in Nature and Antiquity."

This work appears to have been written about 1732; it was translated from the Portuguese, and printed in Pinkerton's Collection of Voyages and Travels. With reference to Wolverhampton, Gonzales says: "The chief manufacturers of this town are locksmiths, who are reckoned the most expert of that trade in England. They are so curious in this art, that they can

contrive a lock so that if a servant be sent into the closet with the master key, or their own, it will show how many times that servant hath gone in at any distance of time, and how many times the lock has been shot for a whole year; some of them being made to discover five hundred or a thousand times. We are informed also that a very fine lock was made in this town, sold for 20£, which had a set of chimes in it that would go at any hour the owner should think fit."

If Gonzales was correct in these descriptions, they indicate an exercise of considerable ingenuity in lock-construction, especially in reference to the lock which keeps a registry of the number of times it has been opened. There is abundant evidence that the old lock-makers were very fond of these knick-knack locks, which would do all sorts of strange and unexpected things; and this may in part account for the great favor in which locks have been held by amateur machinists.

The lock-manufacture in South Staffordshire is of a remarkable character, comprised as it is within so small an area. Although Wolverhampton is known commercially as the chief depot of the English lock trade, yet it is at Willenhall, three or four miles eastward of that town that the actual manufacture is chiefly carried on. When the Commission was appointed a few years ago to inquire into the condition of children employed in trades and manufactures, Mr. R. H. Horne was deputed to examine the Wolverhampton district; and his report is too curious, and too closely connected with our present subject, to be passed unnoticed. We here give an abstract of such parts of his report as bear reference to the lock-makers of Willenhall.

Almost the entire industry of Willenhall is in the three articles of currycombs, locks and keys, and articles connected incidentally with locks, such as bolts and latches. At the time Mr. Horne wrote, in 1841, there were among the master manufacturers 268 locksmiths, 76 key-makers, 14 bolt-makers, and 13 latch-makers; besides many small masters living in such out-of-the-way corners that they escaped enumeration.

In the *Post-Office Directory* of that district, of later date, there are entries of rather a curious character. In the first place it is observable that different kinds of locks are made by different persons, each manufacturer confining his operations apparently to one kind of lock; one is a *rim-lock* maker, another a *trunk-lock* maker, a third a *cabinet-lock* maker, a fourth a *padlock* maker, a fifth a *mortise-lock* maker, and so on.

But a much more singular feature is, that lock-making is combined with retail dealing of a totally different kind; thus among the occupations put down opposite the names of individuals are, "key-stamper and beer-retailer," "door-lock maker and beer retailer," "grocer and trunk-lock maker," "Malt-Shovel tavern-keeper and rim-lock maker," "lock-maker and provision dealer," "grocer and key-maker," "cabinet-lock maker and Woolpack tavern," "key-stamper and registrar of births, etc.," "Hope and Anchor and cabinet-lock maker," "auctioneer and locksmith," "rim-lock and varnish maker," and so forth. It is probable that in some of these cases the wife attends to the retail shop, while the husband attends to the workshop.

Among all the lock-manufacturers of the town there are scarcely half a dozen in what may be termed a large way of business; there are many who employ from five to fifteen pairs of hands, but the great majority are small masters who are themselves working mechanics, and are aided by apprentices from one to four in number, perhaps two on an average.

Mr. Horne thinks that there were not fewer than a thousand boys at work in the town, chiefly upon locks and keys. The children and young persons are employed at all ages, from seven up to manhood; from the earliest age, indeed, in which they are able to hold a file. It is a characteristic fact, where so many of the male inhabitants are employed at the bench from such early years, that a certain distortion of figure is observable; the right shoulder-blade becomes displaced and projects, and the right leg crooks and bends inwards at the knee, like the letter K, it is the leg which is hindermost in standing at the vice. The right hand also has frequently a marked distortion. "Almost everything it holds takes the position of the file. If the poor man carries a limp lettuce or a limper mackarel from Wolverhampton market, they are never dangled, but always held like the file. If he carry nothing, his right hand is in just the same position."

The hours of labor among the small masters are scarcely brought within any system at all; for all the work is piecework, not paid for by the day or hour; and each man works as long as he likes, or as long as his business impels him. Some will file away from four or five in the morning till eleven or twelve at night. In the larger shops, where there are many hands employed, they come to work when they like, leave when they like, and do as much work as they like when there; this freedom of action being spread over a working-day of perhaps sixteen hours.

The masters say that the men prefer this system, or want of system, to anything more precise and regular. In the beginning of the week there is often much idleness and holiday-keeping; and the Willenhall men make up for this by a day of sixteen, eighteen or even twenty hours work towards the end of the week. In the beginning of the week, men and boys have defined hours and definite periods for meals; but towards the end of the week, when hurry and drive are the order of the day, they eat their meals while at work, and bolt their victuals standing.

"You see a locksmith and his two apprentices, with a plate before each of them, heaped up (at the best of times, when they can get such things) with potatoes and lumps of something or other, but seldom meat, and a large slice of bread in one hand; your attention is called off for two minutes, and on turning round again, you see the man and boys filing at the vice."

In the processes as carried on at Willenhall, they are applied chiefly to the manufacture of mortise, box, trunk, rim, cabinet, case, bright, dead, closet, and padlocks. Except some of the parts of the brass-work, which are *cast,* these locks are *made by forging, pressing,* and filing. The forging is a light kind of smith's work, aided by a light hammer and a small pair of bellows; children and young persons are largely employed in this process.

Pressing is a kind of work by which certain parts of the lock are pressed or stamped out. The presses are of various sizes, but all require much strength to work them; the press has a horizontal lever, crossing the top of a vertical screw, and there is generally an iron weight at the end of each arm or half of the lever to increase the power; one of the lever arms is grasped in the right hand of the presser, and whirled round with a jerk; while the fingers of the left hand place the metal in its proper position, and remove it when it has been stamped or pressed.

There is, of course, a die or cutter attached to the press, to cut the metal in the proper form. Sometimes the press has only one arm to the lever, and no weight at the end of this, so that the labor of working is much increased. Children and youths are employed at this process, so far as their strength will admit. The last process, *filing is* that by which the separate pieces are shaped and smoothed for adjustment in their proper places; here children and youths are almost exclusively employed; they stand upon blocks so as to be able to reach the vice, and then work

away with the file, unrelieved by any change in the nature of the process.

In key-making the processes may be said to comprise *forging, stamping, piercing, end fling.* The forging differs very little from that required in making the pieces for a lock. The stamping is effected by placing the end of an iron wire, taken red-hot from the forge, into one half of a key-mold made in a block or kind of anvil; a heavy weight is then raised between an upright framework, in the grooves of which it runs by means of a cord; the cord is drawn by both hands, with the assistance of one foot in a stirrup attached to the end of the cord; at the bottom of the weight thus raised is the other half of the key-mold. Such being the nature of the stamping apparatus, the process is thus conducted: the foot in the stirrup being suddenly raised, and the cord loosed, the weight falls upon the red-hot wire, and the blow stamps it into the two molds or half-molds, which are brought accurately together by means of the slides or side-grooves in the framework.

The rough key is also trimmed and cleared by the pressing apparatus; that is, the surplus metal all round is cut off by a single blow; and the metal which fills up the ring or handle of the key is cut or pressed out in the same way. This is a heavy part of the key-work, for which the labor of men rather than that of boys is required.

The process of *piercing* the key consists in making the pipe or barrel, required for most keys, except those which are intended to open a lock for both sides; the pipe is drilled by a small machine worked with the foot like a lathe; it is a process requiring more skill than strength, relatively to other parts of the manufacture.

The fling of a key is important; for not only is the whole key made bright, but the wards are cut by the file and chisel. Boys and youths are employed in filing the common keys; but those of better quality are entrusted to men.

The apprenticeship system is carried on to a remarkable extent among the lock and key makers of Willenhall. The small masters take apprentices at any age at which they can work. Some of them employ only apprentices, never paying wages for journeymen, but always taking on a new apprentice as soon as a former one is out of his time. The boys are mostly procured from other towns, and they bring with them a small apprenticeship-fee and a suit or two

of clothes. They are bound to the masters by legal indenture or contract; and the masters board and lodge and clothe them during their apprenticeship.

One consequence of this system is that when the apprentice has served his time, he is almost driven to become a small master himself from want of employment as a journeyman; and he then takes apprentices as his master did before him. This accounts for the fact that in Willenhall there are few large manufacturers and few journeymen; while there is a constantly-increasing number of small masters and of apprentices.

The Willenhall makers nearly all look to the Wolverhampton factors or dealers for a market for their wares, for at least as concerns locks and keys; there are some other articles which they sell more frequently to Birmingham houses. The master and an apprentice, or perhaps two, generally trudge off to Wolverhampton on a Saturday, bearing the stock of locks which he may have to sell; and the money receipts for the locks or keys sold are usually in part spent at the large market of Wolverhampton previous to the homeward journey.

The Willenhall men take contracts at so low a price as to prevent the competition of other places; it is stated, that whatever be prices elsewhere, nothing can come below the Willenhall prices for cheap locks. The men work hard for small returns, and yet they have a strong yearning for their own town. A Willenhall girl will seldom marry except to a townsman; and thus they intermarry to an extent which maintains their characteristics as a peculiar community.

As an example of their disinclination to leave their own town, Mr. Horne states the following circumstance: "Some years ago a factor, who had projected a manufactory in Brussels, engaged some five-and-twenty Willenhall men, whom he was at the expense of taking over. He gave them all work, and from hard-earned wages of from 9s. to 15s a-week, these 'practiced hands' found themselves able to earn 3£ per-week and upwards.

But they were not satisfied, and began to feel uncomfortable; first one left, and returned home; then another; then one or two; until, in the course of a few weeks, every man had returned to Willenhall, there to work harder and earn less.

It is just possible that the application of the factory system to lock-making may first become important by making the *best* locks

cheaper than they can be made by the handicraft method; for there seems not much probability, at least for a great length of time to come, that any new system will be able to compete with Willenhall in the common locks, those of which more thousands are sold than there are tens of the better locks. In this, however, it would not do to predict rashly. Hand-loom weaving is cheap enough, unfortunately for those who practice it; but yet the factory system comes down as low as the lowest hand-loom weaving.

The editor of Hebert's *Encyclopedia,* after noticing the facilities for opening most locks by copying the key, makes the following announcement: "It affords the editor of this work much satisfaction to state, that he has in his possession a lock, the key of which *cannot be copied,* a locksmith possessing no tools by which an exactly similar one can be made; the machine by which the original one was made is so arranged as to be deprived of the power of producing another like it. The lock is very simple, very strong, and can be very cheaply made. The cost of a complete machine to make them would be about 100£; with that they might be manufactured at one-half the expense of any patent lock. The inventor is desirous to have the subject brought before the public under a patent; but want of time to devote himself to such an object at present obliges him to lay it aside."

The invention not being patented, the editor of course gave no diagram or engraving of the lock or machine; nor does there appear to have been a patent obtained during the sixteen or eighteen years which have elapsed since the above notice was published. There are, however, mechanical principles sufficiently well known to lead to a belief that such a machine is practicable; a ticket-printing or numbering machine will, in printing 100,000 tickets, produce such variations that no two impressions shall be identical; and a key-making machine might, after fashioning a particular part of each key, modify the arrangement of certain wheels and pinions so far as to produce a slightly different result when the next key is to be operated on.

In the manufacture of locks and keys generally there is no reason why the factory system should not, to a certain extent, be applicable. By this will be understood, the production of similar parts by tools or machines, graduated in respect to each other with more care than can be done by the hand method.

If we suppose that a lock of particular construction comprises twenty screws and small pieces of metal, and that there are required, for general disposal in the market, five sizes of such

a lock; there would thus be a hundred pieces of metal required for the series, each one differing, either in shape or size, from every one of the others. Now, on the factory or manufacturing system, as compared with the handicraft system, forging, drawing, casting, stamping, and punching, would supersede much of the filing; the drilling machine would supersede the drill-stock and bow, and other machines would supersede other hand-worked tools.

This would be done, not merely because the work could be accomplished more quickly or more cheaply, but because an accuracy of adjustment would be attained, such as no hand-work could equal, unless it be such special work as would command a high rate of payment. For any one size in the series, and any one piece of metal in each size of lock, a standard would be obtained which could be copied to any extent, and all the copies would be like each other.

To pursue our illustration, the manufacturer might have a hundred boxes or drawers, and might supply each with a hundred copies of the particular piece of metal to which it is appropriated, all so exactly alike that any one copy might be taken as well as any other. Ten pieces, one from each of ten of these boxes, would together form a lock; ten, one from each of another ten boxes, would form a second lock, and so on; and there would be, in the whole of the boxes, materials for a thousand locks of one construction, a hundred of each size.

Now the advantage of the machine or factory mode of producing such articles is this, that they can be made in large numbers at one time, whenever the steam-engine is at work; and that when so made, the pieces are shaped so exactly alike, the screws have threads so identical, and the holes are bored so equal in diameter, that any one of a hundred copies would act precisely like all the others, thereby giving great advantages to the men employed in putting the lock together.

These principles are being applied by Messrs. Hobbs and Co. in their London establishment. A number of machines, worked by steam-power, are employed in shaping the several pieces of metal contained in a lock; and all the several pieces are deposited in labeled compartments, one to each kind of piece. The machines are employed, in some cases to do coarse work, which they can accomplish more quickly than it can be done by men; and in other cases to do delicate work, which they can accomplish more accurately than men; but so far is this from converting the men into lowly-paid automatons (as some might suppose), that the

manufacturers are better able to pay good wages for the handicraft labor necessary in putting the locks together, than for forming the separate parts by hand; just as the "watchmaker," as he is called, who puts the separate parts of the watch together, is a better-paid mechanic than the man who is engaged in fabricating any particular parts of the watch.

It may be observed that the system of manufacturing on a large scale, by many men engaged in one large building, is more nearly universal in the United States than in England. The workshop system, as pursued at Willenhall by the lock makers, is very little practiced in America. Being comparatively a new community, and being at liberty to select for imitation or for improvement whichever of the usages or systems in the old country they may prefer, the Americans have preferred to adopt the factory system rather than the workshop system, and to carry out the former to an extent not yet equaled in England; not yet equaled, we mean, in the number of trades to which it is applied.

CHAPTER TWELVE: English Patents for Locks-Aubin's Lock Trophy

WE propose to conclude this small work with a few details respecting the various patented inventions in locks, and concerning Mr. Aubin's remarkable lock trophy. These two subjects relate to locks in general, rather than to any specified constructions in particular, and can on that account more conveniently be given here than in connection with any of the foregoing chapters.

Mr. Chubb, in the appendix to his paper on LOCKS and KEYS read before the Institution of Civil Engineers, gave a useful list of all the patents taken out in England in relation to this subject, down to the year 1849. We here transcribe this list:

List of Patents for Locks and Latches granted since the Establishment of the Patent Laws.

AS no complete list of the patents granted for locks from the time of James I. has hitherto been published, it is believed that the following list, which has been very carefully drawn up, and which comprises all patents from the year 1774, when the first patent for a lock was granted, to the present time, will be found useful as a reference {for all who are interested in the Subject).

1774	**May**	**27**	**Black, George, Berwick-on-Tweed.**
1774	**May**	**27**	**Barron, Robert, London.**
1778	**May**	**29**	**Martin, Joshua Lover, Feet-street, London.**
1779	**May**	**28**	**Henry, Solomon, Swithin's-lane, London.**
1780	**March**	**4**	**Campion, J. Newcastle-court Strand, London.**
1782	**January**	**18**	**Hutchinson, Samuel, Marylebone, London.**
1784	**January**	**18**	**Bramah, Joseph, Piccadilly, London.**

1789	July	7	Cornthwaite, Thomas, Kendal, Westmoreland.
1790	February	23	Rowntree, Thomas, Surrey-streot, Blackfriars London.
1790	October	29	Bird, Moses, Wardour-street, London.
1791	July	19	Ferryman, Rev. Robert, Gloucester.
1791	November	3	Antis, John, Fulneck, near Leeds.
1797	November	18	Langton, Daniel.
1798	May	3	Bramah, Joseph.
1798	December	8	Turner, Thomas.
1799	April	11	Davis, George.
1801	February	10	Scott, Richard, Lt. Colonel.
1801	June	24	Holemburg, Samuel, London.
1801	June	24	Roux, Albert, Switzerland.
1805	May	18	Stansbury, Abraham Ogier, New York.
1805	December	29	Thompson, William, Birmingham.
1815	March	7	Mitchell, William, Glasgow; and Lawton, John, London.
1816	May	14	Ruxton, Thomas, Esq., Dublin.
1817	February	8	Clark, William, Esq., Bath.
1818	February	3	Chubb, Jeremiah, Portsea.
1819	October	18	Strutt, Anthony Radford, Mackeney.
1820	April	11	Jennings, Henry Constantine, Esq., Middlesex.
1820	December	14	Mallett, William, Dublin.
1823	July	10	Fairbanks, Stephen, Middlesex.
1823	November	13	Ward, John, Middlesex.
1824	June	15	Chubb, Charles, Portsea.
1825	May	14	Young, John, Wolverhampton.
1828	May	17	Chubb, Charles, London.
1829	June	1	Gottlieb, Andrew, Middlesex.
1830	January	18	Carpenter, James, and Young, John, Wolverhampton.
1830	January	26	Arnold, John, Sheffield.
1831	April	14	Rutherford, William Jedburgh N.B.
1831	May	23	Barnard, George, Bristol.
1831	July	27	Young, John, Wolverhampton.
1832	December	20	Parsons, Thomas, London.
1833	December	3	Parsons, T., Newport, Salop.
1833	December	20	Chubb, Charles, London; and Hunter, E. Wolverhampton.
1834	September	6	Longfield William, Otloy.
1834	October	11	Audley, Lord Barron Stafford.
1835	March	18	Hill, H., Birmmgham.
1835	December	16	Warwick, J., London.

1836	February	21	Fenton, Rev. S., Pembroke.
1838	June	30	Uzielli M., London.
1838	November	13	Thompson, S., London.
1839	February	21	Uzielli M., London.
1839	June	12	Sanders, J. Stafford.
1839	July	3	Cochrane, A., Strand, London.
1839	July	20	Schwieso J. C., London.
1839	August	1	Williams, W. M., London.
1839	December	2	Guest, J., jun., Birmingham.
1840	February	27	Williams, W. M., London.
1840	March	20	Gerish, F. W.
1840	May	2	Pearse, W., Hoxton, Middlesex.
1840	June	13	Wolverson, J., and Rawlott, W., Stafford.
1840	October	22	Clark, T.
1840	December	23	Baillie, B., London.
1841	March	29	Tidesley and Sanders, Willenhall and Wolverhampton.
1841	May	6	Hancock, James, Sidney-square, Mile End.
1841	July	14	Berry, Miles, Chancery-lane.
1841	September	28	Strong, Theodore Frederick Goswell-road.
1841	November	9	Smith, Jesse, Wolverhampton.
1842	January	15	Poole Moses, Lincoln's-inn.
1842	May	24	Duce, Joseph, Wolverhampton.
1842	June	13	Williams, W.M., 163 Fenchurch-street.
1842	December	29	Rook, Joseph, jun., Birmingham.
1843	November	25	Tann, E.E. and J., Hackney-road.
1843	November	25	Rock, Joseph, jun., Birmingham.
1844	July	30	Fletcher, Rev. William, Moreton House, Buckingham.
1845	April	15	Carter, George, Willenhall.
1845	July	12	Ratcliff, Edmund, Birmingham.
1845	December	4	Poole, Moses, Lincoln's-inn.
1845	December	22	Smith, Philip, High-street Lambeth.
1846	July	6	De la Fons, John Palmer, Carleton-hill, St. John's Wood.
1846	July	15	Thomas, William, Cheapside.
1846	December	14	Chubb, John, St. Paul's Churchyard.
1847	January	11	Chubb, John, and Hunter, Ehenezer, sen., St. Paul's Churchya
1847	April	15	Collett, Charles Minors, 62 Chancery-lane
1848	September	28	Newell, Robert Stirling, Gateshead.
1849	May	8	Wilkes, Samuel, Wednesbury-heath, Wolverhampton.

Mr. Chubb also gave a list of such papers in the Transactions of the Society of Arts as refer to locks and keys.

List of References to the "Transactions of the Society of Arts," on the subject of Locks.

vol	page.	
1.	317	Mr. Moore.
2.	187	Mr. Cornthwaite
3.	160	Marquis of Worcester.

Among the most curious mechanical productions in the Great Exhibition of 1851, was one that attracted very little notice, viz. that forwarded by Mr. C. Aubin of Wolverhampton. Whether it was that attention, so far as regards locks, was too much absorbed by the "lock controversy," or whether there was a deficiency of descriptive cataloging, no juror or newspaper critic, as far as we are aware, took notice of the production in question. In the *Official Illustrated Catalogue* it is entered simply as "Specimens to illustrate the rise and progress of the art of making locks, containing forty-four different movements by the most celebrated inventors in the lock trade."

This trophy of lock ingenuity (for such it may be justly considered to be) is now in the possession of Mr. Hobbs. Springing from a hexagonal base-piece is a central axis, about three feet in height, supporting four horizontal circular discs, placed at different parts of its height. Each of the vertical faces of the base-piece contains a lock, which is worked by its respective key. Each disc contains a number of locks: sixteen on the lowest, twelve on the next above, nine on the third in height, while a Bramah lock surmounts the whole.

All the locks on the discs are so arranged that their bolts shoot outwards, or radially away from the axis of the machine. Every lock has its own proper key inserted in the keyhole; and as the locks lie down horizontally, the shaft of each key is of course vertical.

There are delicate pieces of mechanism contained within the central axis and within the discs, consisting of levers, racks, and pinions; and the Bramah lock is contrived so ingeniously, that the Bramah key, by acting upon that lock, acts upon all this mechanism. The Bramah barrel, in rotating horizontally under the action of its key, gives a rotary movement to a rod passing vertically through the center of the whole apparatus; this rod, at the levels of the several discs, acts upon racks and pinions, and these in turn act upon the key-pins of the several locks.

When, therefore, the Bramah key is turned, the whole of these key-pins rotate, each exactly in the same way as if the lock were being closed or opened, and the bolts shoot in or out accordingly. The Bramah key, although it acts as a master key, is not such as usually obtains that designation; it is simply a means of putting in action certain rack-and-pinion mechanism, which does not belong to lock-work considered *per se.*

All the locks are faithful representatives of the several patents or modes of construction to which they severally refer; and each exhibits the works sufficiently open to display the principle on which it is arranged. Each lock is numbered, and is referred to in an accompanying description. The works are finished with the utmost care and polish; and the trophy being somewhat tastefully arranged, and kept under a glass shade, forms a really elegant specimen of mechanical skill.

For an account of the locks themselves that constitute this trophy, we cannot do better than avail ourselves of the description given in the article "Lock" in Tomlinson's *Cyclopedia of Useful Arts,* adding a few further details in respect to some of the locks of the series. The locks are arranged and numbered according to their similarity of construction; and it is instructive to remark the evidence here afforded, that many patentees would have caved much time and money if they had better known the productions of their predecessors. In describing these locks we shall do so briefly, sufficient to show their relative principles of construction; many of them having been described more or less fully in former chapters.

No. 1 on the list is called a *Roman lock; it* consists of a single bolt, with a binder-spring for holding the bolt in any position in which it may be placed until a sufficient force is applied to overcome it: it embodies the simple principle on which thousands of common locks are annually made.

No.2, called a *French lock* (all such designations are of rather doubtful correctness), resembling No. 1 in everything except having the addition of a friction-roller. The bolt of either of these two locks can easily be forced back by pressing on the end.

No. 3 is marked *Ancient;* it is a bolt-lock, and was found in an ancient building. It exhibits an improvement on both the former specimens, in so far as the bolt requires, before it can be shot, to be pressed down, in order to release it from a catch at the back end of the bolt; this release cannot be effected without the aid of a key or some other implement applied through the keyhole, and thus the bolt answers the purpose both of bolt and tumbler.

No. 4, also marked *Ancient, is* in principle a single-acting tumbler-lock; that is, one in which the tumbler may fail to be lifted high enough, but cannot be raised too high, to release the bolt: whereas a double-acting tumbler, being susceptible both of too much and too little ascent, must be raised to one definite and precise height to attain the required object.

No. 5, an *old English lock,* exhibits a great advance in principle, being provided with the double action just described AS being wanting in No. 4.

No. 6, *modern English* (no maker's name), is a single-acting tumbler-lock.

No. 7, by *Mace* is a double-acting tumbler, but without exhibiting any peculiarities of construction.

No. 8 is *Somerford's first patent.* It is a double-acting *draw* tumbler-lock; that is, there is a tumbler which is drawn down instead of being lifted, as in most locks.

No. 9, designated, we know not on what grounds, an *Indian* lock, has a single-acting tumbler with a pin.

No. 10, patented by Thompson in 1805. In this lock there are two tumblers, one of which is single and the other double-acting.

Next follow a considerable number of locks, which differ one from another too slightly to render any formal description necessary. No. 11, by *Daniells,* is a single-acting tumbler, differing only in form from those previously used. No. 12 is by W*alton.* No. 13 is *Barron's* first patent, taken out in 1774. No. 14 is by *Bickerton.* No. 15 is a *Dutch* lock. No. 16 is by *Duce* senior. No. 17, by *Sanders, is* a lock with four double-acting tumblers. No. 18, patented by *Cornthwaite* in 1789, is so nearly like Sanders's, brought before public notice in 1839, as to corroborate what we have said concerning the identity, or at least close resemblance, of inventions widely asunder in point of time. No. 19 is by *Richards and Peers.*

No. 20 is *Somerford's* second patent; a lock which seems to embody the principle of Hr. Tann's "reliance-wards," patented many years later. No. 21 is *Rowntree's* lock, patented in 1790. No. 22 is the first patent lock of *Duce* junior, dated 1823. No. 23 is *Parsons'* first patent, of 1832. No. 24 is *Bickerton's* second. No. 25, patented by Price in 1774; this, so far as at present appears, was the first lock ever constructed with four double-acting tumblers, bearing a closer resemblance than would generally be supposed to those patented by other persons in more recent years. No. 26 exhibits a somewhat similar coincidence. It was introduced by Aubin in 1830, and is furnished with a *revolving curtain* for the purpose of closing the keyhole during the revolution of the key. Other inventors have since then adopted the revolving curtain; and in a patent taken out so recently as 1852, this appendage is claimed as part of the patent.

No. 27 *is Barron's* second patent, dated 1778; a lock which has perhaps been the model for a larger manufacture of plain simple tumbler-locks then any other. No. 28 is by Bird, 1790. No. 29 is the second patent of *Duce* junior. No. 30 is *Ruxton's,* 1818. No. 31 is *Chubb's* simplified lock, 1834. No. 32 is by *Marr.* No.33, by *Tann, is* the "reliance-ward" lock adverted to above as having been anticipated, in respect to its leading principle, by *Somerford's* second patent. No. 34 is by *Hunter,* 1833. No. 35 is *Parsons'* second patent, of the same year. No. 36 is by *Lang,* 1830. No. 37 is *Lawton's* dated 1815. No. 38, patented by *Strutt* in 1839, has an arrangement for holding the tumblers, in the event of a pressure being applied to the bolt; an arrangement bearing a considerable resemblance to one recently adopted in Chubb's bankers' lock. No. 39 is by *Scott,* 1815. No. 40, *Chubb's* patent of 1818, is the original detector-lock of this maker. Most

of the detectors since patented by various persons are little other than variations of Chubb's original.

No. 41, *Parsons'* third patent of 1833, is a *changeable* lock of peculiar construction. The elevation of the tumblers is regulated by an adjusting-screw passing through the lock to the inside of the door; this screw changes the positive but not the relative positions of the tumblers; so that the same difference in the steps of the key must be retained, the change being made only in the length of the bit: the number of changes for each lock is very limited.

No. 42, invented by *Pierce* in 1840, seems to be a carrying out of the plan suggested by the Marquis of Worcester in his *Century of Inventions,* where he says that "a lock may be so constructed that if a stranger attempteth to open it, it catches his hand as a trap catcheth a fox; though far from maiming him for life, yet marketh him so, that if once suspected he might easily be detected."

In Pierce's lock a steel barb or sharp arrow-head is concealed below the keyhole, in such a manner that if any person in attempting to open the lock should over-lift the tumbler, the barb would be thrust by a spring into his hand. It is said that the patentee himself experienced the efficacy of this invention, by receiving the barb into his own hand.

No. 43, by *Burton,* patented in 1816, is furnished with a tell-tale, so arranged that if the tumbler be over-lifted in an attempt to pick the lock, a pin or catch is thrown out from the lock, which would be visible on opening the lock with the proper key. This invention preceded Chubb's detector by two years, and would be entitled to some of the honors of originality were not Chubb's arrangement much more simple and effective.

No. 44 is *Bramah's* patent of 1784, and the crowning lock of the trophy, by which all the others are opened. Similar locks by *Russell* and *Mordan* are applications of the Bramah principle, with little or no variation.

No attempt has been made in these pages to describe every variety of lock that has been introduced. Several forms of puzzle locks, known as *Russian* and *Chinese Locks,* have the forms of various animals, and they are locked and unlocked by pressing upon or moving some portion of the body of the animal: the security of such locks depends in many cases upon keeping the part to be

pressed or moved secret.

There are also various forms of alarm locks; but these do not greatly differ from common locks, except in having certain appendages, such as a pistol, which if loaded and properly adjusted, will be fired on any attempt being made to open the lock, either with its own key or some other instrument.

Some locks are furnished with a bell or a rattle, which is rung or sprung on attempting to open the lock, and in this way the inmates of the house are informed of the attempt to effect an entrance. It will, however, be evident to anyone who has read the preceding pages that devices of this kind do not add to the security of the lock; they rather tend to degrade the art of the locksmith to that of the toy-man. The locksmith, in common with every other artist, can only improve in his art by studying the principles upon which it rests, and illustrating them by the most approved examples which the constructive genius of his predecessors or contemporaries has furnished.

APPENDIX.

CHAPTER THIRTEEN: On an Improved Construction of Lock and Key

*By J. Beverley Fenby, Mechanical Engineer, of Birmingham. Extracted chiefly from the Proceedings of the Institution of Mechanical Engineers, 1866.

THE simple fixed-guard or *warded* lock is SO utterly worthless for security, no matter what amount of good workmanship be bestowed upon it, that it demands but short notice. It was contrived with the intention of making the passage to the bolt intricate; but it will be seen at once that this intricacy does not really offer any security. The wards of a lock are circular arcs of thin metal, so arranged as to require a key of peculiar pattern to pass amongst them, the shape of the cuts in the key being a

section of the wards. The fixed-guard or warded lock was the one in general use in the middle ages.

To make a really complicated box of wards, and to cut keys which shall accurately fit their sweep is a matter requiring considerable manual dexterity; and some warded locks are therefore expensive. But even with the best of them, all that it is necessary to do for opening the lock is to take a blank key which will properly fit the keyhole, coat it with wax, and then inserting it in the lock, press it round against the wards, which will cause them to leave an accurate impression of their section on the key.

The parts impressed are then cut out with small files, drills, and saws, and the occasional use of fine cross-cut chisels. The key will then pass those wards which impressed themselves upon it; and if these are the only wards, it will go completely round and open the lock. If there are also other wards in addition, not brought up flush with the first wards, the key is waxed again and pressed against them, and then further cut out as before. This process is evidently one of absolute certainty, and the key so made is in all respects as capable of mastering the lock as the original key.

These warded locks are however easily opened with merely a piece of bent steel wire, bent into such a sweep as will reach right round the wards instead of passing amongst them, thus escaping all chance of being obstructed by them. Such an instrument *is* called by burglars a "twirl."

The next kind of lock is the *tumbler* lock, in which the bolt is moved backwards and forwards by the key as usual, but these movements cannot take place until a small lever with a stump on one side be lifted. This lever and stump form the tumbler, which is held down by a spring; and in the tail of the bolt are two notches, into one of which the stump fits when the bolt is shot, and into the other when it is withdrawn. All that is necessary to effect the picking of this lock is to lift the tumbler high enough for clearing the stump out of the notch, and then draw back the bolt. The tumbler may be lifted with one pick, and the bolt drawn back with another; but generally one pick will suffice for both purposes.

In the Barron tumbler lock the principle of double-action was introduced. The next improvement was the *lever* lock properly so called, under which designation the majority of the modern locks

may be classed.

The Bramah lock was an admirable contrivance with remarkably beautiful mechanism contained in a small compass; and since its invention there have been several ingenious modifications of the same principle in different radial locks, such as the Yale lock, in which the slides move radially instead of axially. One advantage in these radial locks is the greater difficulty in copying the keys, in comparison with the flat keys of ordinary lever locks: this difficulty however is not an insurmountable one.

A very ingenious addition was made to the action of the lever lock in Newell's American lock, which was shown in the 1851 Exhibition, and described within this present volume.

Though locks such as those already referred to exhibit great dissimilarity of construction, yet there is one point in which they all agree, and that is in the possession of a direct passage from the outside to the works. Although various locks have been devised with the object of having no direct passage to the works from the outside, one consideration shows the inevitable existence of such a passage; namely, that without it the key could not possibly at one and the same time touch the hand of the operator and the works of the lock. It therefore follows that any instrument which can pass in the same space as the key may be brought to bear on the works, whatever may be their construction.

It can now be shown that, if picking instruments are thus brought to bear on the works through the keyhole, there is a regular tentative system whereby the picking of any lock with an open keyhole can sooner or later be effected.

From the foregoing observations it is evident that there are two important defects in the principle of the previous lever locks, which being defects in principle are fatal to their security; namely, the means of access to the works of the lock through the keyhole, allowing of a series of attempts being made to open the lock by picking instruments; and also the facility afforded for repeating the trial of a false key made from a wax impression of the true key, and thus perfecting it by successive alterations after trial.

In consequence of the possibility thus allowed of making these successive attempts either by picking instruments or by a false key, it has been shown by the cases that have occurred of locks

of the best makes which have been falsely opened, that, however numerous and complicated may be the secondary impediments introduced into these locks, there can be no real security against the ultimate success of sufficiently numerous and persevering attempts, except by the adoption of some new principle of construction specially meeting the above two defects.

In the invention of the Improved Lock and Key now to be described, and which has been termed the ***adytic*** lock, the writer's object has been to meet this requirement. In **figure 53** is shown an elevation of this lock, such as is made for an iron safe; two of the front cover plates being removed to show the construction.

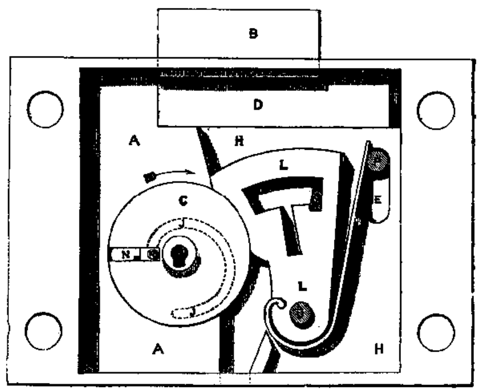

Figure 53

The head **B** of the main bolt is of such a thickness as to be flush with the face of the levers **L** and guard **A;** and the strap or tail **D** of the bolt is thin, and passes behind the levers and guard, and also behind the plate **H H.** The part of the tail **D** which would lie under the levers **L** and cylinder **c** is removed, as seen in **figure 54**, and replaced by a separate flat plate or stump-bolt, carrying the stump **S.** This stump bolt has a projection **K** upon it, let into a recess in the tail **D** of the main bolt, but with 1/10th inch vertical play in the recess. A spring in the tail of the main bolt presses the stump-bolt downwards, keeping the stump **s** in the notches of the levers **L**, as shown in **figure 54.**

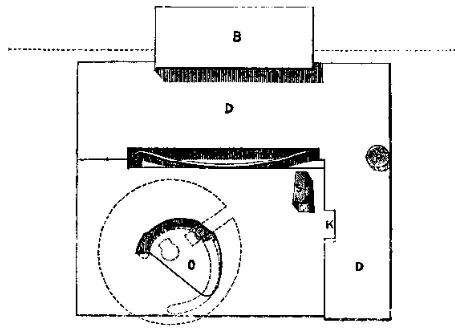

Figure 54

The stump-bolt can thus descend 1/10th inch at first without moving the main bolt, and this amount of vertical movement is sufficient to carry the stump in and out of the notches in the levers; but the stump-bolt cannot descend further without taking the main bolt with it.

Immediately in front of the bolts come the fixed plate **H H.** in which is cut the cam groove shown by the dotted line **J J**; and also the vertical slot **E** for the pin **P** to work through, together with another vertical slot in which the stump s fits and works. This plate carries the center pin **u** on which the levers **L** turn.

The levers are six in number, though any other number may be used; and they occupy collectively 3/8ths inch thickness. In front of the plat **H** is fixed the guard **A**, which is made of iron or steel, and has the brass cylinder **c** ground into it.

The guard is made a shade thicker than the levers **L** in order to prevent the back plate **H** and the corresponding front plate from being so tightened on the levers as to impede their freedom of movement. The cylinder **c** is the same thickness as the levers, excepting the center boss **F**, which projects from the back of the cylinder and works in a bearing in the back plate **H** and also projects in front through the thickness of the two front cover plates.

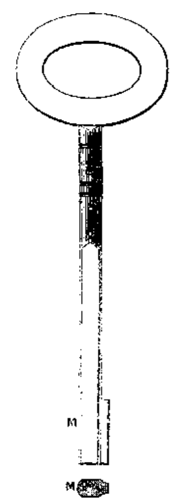

Figure 55

The small keyhole in the center of the boss goes only a short distance into the cylinder **c**, being merely for the purpose of enabling the stem of the key **M figure 55**, to turn the cylinder; the bit of the key is a separate piece, **N. figure 57**, which is inserted through a separate keyhole into the radial slot of the

revolving cylinder **c**, as shown at **N** in **figure 53**.

This radial slot is cut in the side of the cylinder **c** that is furthest from the levers when the cylinder is in the position shown in **figure 53**; and in the slot fits the slide block **R** which is a steel block having a pin projecting on each side. The back pin enters the guide groove ***J J*** in the back plate **H.** as shown by the dotted line, and the front pin enters the corresponding guide groove in the front cover plate, which is shown removed. The back pin of the slide block projects through the back plate **H.** as shown in **figure 56**, and works in the cam groove **o** in the tail of the stump-bolt **s**, **figure 54**, which is so shaped that as the slide block travels round the guide groove ***J J.*** shown by the dotted lines, it moves the stump-bolt vertically as may be required according to the position of the bolts and levers.

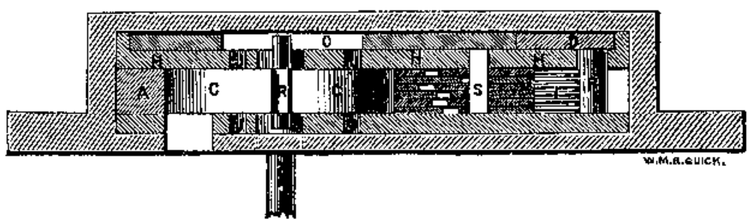

Figure 56

In the position of the lock shown in **figure 53**, the bit **N** has been inserted into the vacant space of the radial slot in the cylinder **c**, in front of the slide block **P**. The size of this vacant space is 3/8ths inch long by 1/8th inch wide and 3/8ths inch deep; and in the two front cover plates of the lock, and also in the door to which the lock is attached, a hole is made of the same shape. In the door there is no bearing for the center boss **F** but only a small keyhole corresponding in size with that in the boss **F** for
inserting the stem of the key.

In the position of the parts shown in **figure 53**, it will be seen that the levers **L** are held pressing down against the circumference of the cylinder **c** by their springs **I** bearing against the pin **P**. In this position also the bolt spring between the main bolt and the stump-bolt, **figure 54**, presses the stump **s** down into the notches of the levers, so that the levers are completely locked by the stump, as seen in **figure 53**.

In order to unlock the lock, which in **figure 53** is shown with the

bolt shot, it is necessary that all the gatings **G** in the levers should be brought precisely under the stump **s**. Through the center keyhole **F** there is no communication possible at any time with the levers **L** nor will any instrument, however slender, if passed into the radial slot through the aperture at **N** be able to reach them, whether the cylinder **c** be in the position shown in **figure 53** or turned round into any other position. For the only difference made by turning the solid cylinder **c** is that the radial slot in it is carried away from the aperture in the external plates, and the solid part of the cylinder is brought opposite to the aperture, which is thereby completely closed against the insertion of a picking instrument.

This construction accordingly not only precludes the possibility of opening this lock with an ordinary key, in which the part that acts on the levers is attached to the stem of the key, but it also renders it an absolute impossibility to introduce a pick of any form, as nothing can reach the levers except a detached piece of such a size and shape as to be capable of traveling round in the vacant space left in front of the slide block **R** in the radial slot of the cylinder **c**.

For the purpose of unlocking the lock, the bit **N**, **figure 57**, is used This bit is of such a size as to fit into the vacant space of 3/8 x 3/8 x 1/8 inch in the radial slot of the cylinder **c**; and the indent at **v** is merely for the purpose of ensuring the insertion of the bit in the right direction, the external aperture for the bit being made with a corresponding projection to fit the indent in the bit. This bit being inserted through the aperture in the door, is pushed in by means of the key stem **M**, which is flattened on two sides for that purpose, as shown in **figure 55**; and the bit is thus pushed home into its place in the radial slot of the cylinder, as shown at N, **figure 53**.

The key stem **M** is now inserted into the center keyhole **F**, and the cylinder is turned round by it in the direction shown by the arrow, carrying round the slide block **R** and the bit **N**. The slide block **B**, while moving through the concentric portion at the commencement of the guide grooves ***J J***, does not affect the bit; but by means of the cam groove **o** in the tail of the stump-bolt, **figure 54**, it moves that bolt so far as to lift the stump **s** completely out of the notches in the levers **L** which are thereby left free to be raised. On continuing to turn the cylinder **c**, the eccentric part of the guide grooves **J J** causes the slide block **R**

to move outwards along the radial slot, pushing the bit **N** before it; and the bit is thus made to project beyond the circumference of the cylinder, which it can then do, being no longer confined by the guard **A**.

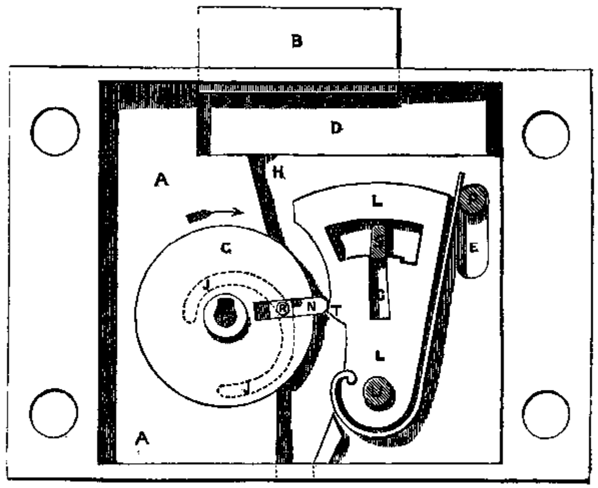

Figure 58

The further projection of the bit as the cylinder revolves causes the steps in the bit to lift their respective levers; and the steps in the bit are so arranged that, when the cylinder arrives at the position shown in **figure 58**, all the gatings **G** are brought simultaneously opposite the stump **s**, which is instantly shot down through the distance of the 1/10th inch play by the bolt spring. The bit **N** remains in contact with the extreme part ***T*** of the levers while the stump **s** is entering the gatings, the action of the bolt spring being so rapid that the bit cannot move through any appreciable distance during the time.

In other locks a spring action of this kind would greatly facilitate the picking, inasmuch as it would afford the gentle uniform pressure desired upon the levers. In other locks, therefore, the bolt is caused to move, and the stump to enter the gatings, by the direct contact of the key with the bolt, instead of by a spring; but as the key, while moving the stump into the gatings, is also altering its position under the levers, a slight tremulous motion of the levers is thereby occasioned, which no care in manufacture can obviate.

This tremulous motion is aggravated by the circumstance that, as the keyhole is open to inspection, it is necessary to make all the levers fit flush with one another when down, in order to

avoid affording any clue to the shape of the key from the positions of the levers; but as the various steps of the key, being of different lengths, describe different arcs, the curves of the levers when raised are of necessity in error to them all.

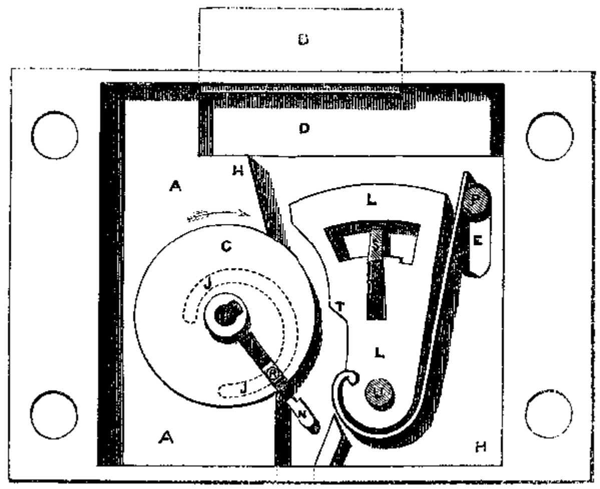

Figure 59

The result of these combined faults is that the gatings have to be made wider than the stump, to allow a sufficient amount of play, thus introducing a fatal element of insecurity in the construction of the lock, since the security is of course enhanced in proportion as the gatings fit the stump accurately.

In the new lock, on the contrary, the arc ***T*** **figure 58**, in each lever, can be shaped truly to its own proper radius, independent of all the rest of the levers; and as the action of the stump is instantaneous in catching the gatings as soon as they are all brought simultaneously under it, the stump and gatings can be made to fit one another with the most perfect accuracy, and without the slightest play.

On turning the cylinder **c** further round, the bit **N** passes from under the levers, which remain held back by the insertion of the stump in the gatings; and just before reaching the position shown in **figure 59**, the slide block **R** has pushed the bit completely out of the radial slot, and the bit falls down as shown in **figure 59**, and drops through a hole into the inside of the safe that is locked.

At this point the back pin of the slide block comes in contact with the lower side of the cam groove **o** in the stump-bolt, **figure**

54; and by turning the cylinder **c** onwards to the position shown in **figure 60**, the withdrawal of the bolt **B** is completed, bringing the parts into the position shown in **figure 60**.

In these drawings only one lever **L** is shown; but there are altogether six levers, as shown in the sectional plan, **figure 56**. The pin **P** is fixed in the tail **D** of the main bolt, so as to travel with the bolt; and by this means the springs **I** are released from strain, as shown in **figure 60**, as soon as the bolt is withdrawn.

From the nicety with which the various parts of this lock are constructed, it is evident that the levers must be very accurately lifted by the bit of the key in order to withdraw the bolt; and therefore any error in the bit, such as would occur with a false bit, will effectually prevent the lock from being opened. This may be illustrated by supposing the false bit to be so close an imitation as to have five of its steps absolutely correct, and the sixth only slightly wrong: though it is almost impossible that such a near approach to correctness could be attained in practice.

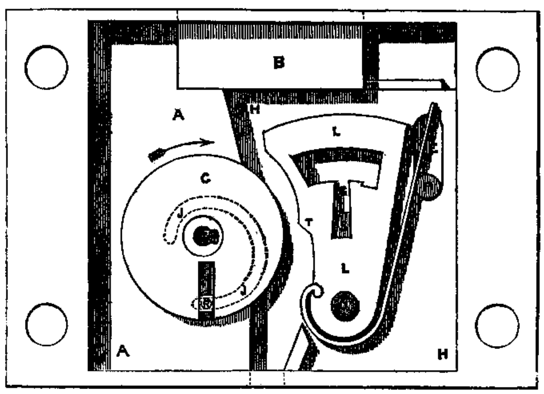

Figure 60

The counterfeit bit being inserted in the lock, and the cylinder turned round, all will go on the same as with the true bit, up to the time when the false bit reaches the point **T** of the levers, as previously shown with the true bit in **figure 58**. Here a change of action takes place; but what is the nature of the change the operator has no means as yet of ascertaining. In the case supposed, where five of the steps in the bit are right, but the sixth is wrong, the gating of the sixth lever does not precisely coincide with the others, nor with the stump **a**; and the consequence is that, at the critical moment when the stump ought

to spring into the gatings and hold back the levers from falling forwards, it will be prevented from entering the gatings, owing to the entrance being partly blocked up by the one lever, which stands more or less across it.

The fact, however, that the stump cannot enter the gatings does not become known to the operator until the cylinder c has been turned further round, so as to bring the slide-block pin in contact with the lower side of the cam groove **o** in the stump-bolt; and before this point has been reached the false bit has already passed clear of the levers, which, not being retained by the stump, are instantly thrown forwards again by their springs, and locked in their original position by the stump entering the notches. At the same time the false bit has dropped into the inside of the safe in the same manner as the true bit, as shown in **figure 61**.

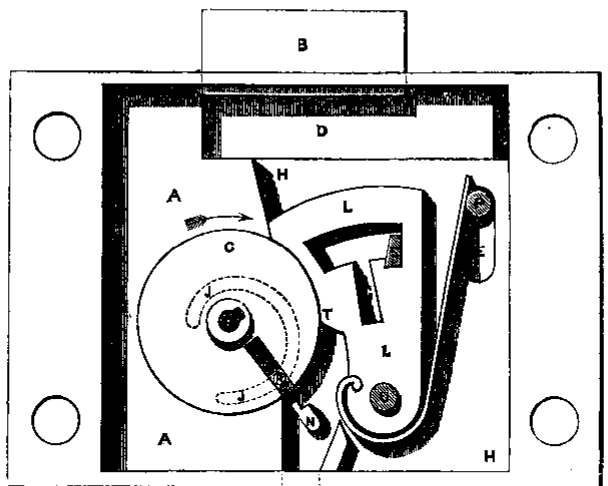

Figure 61

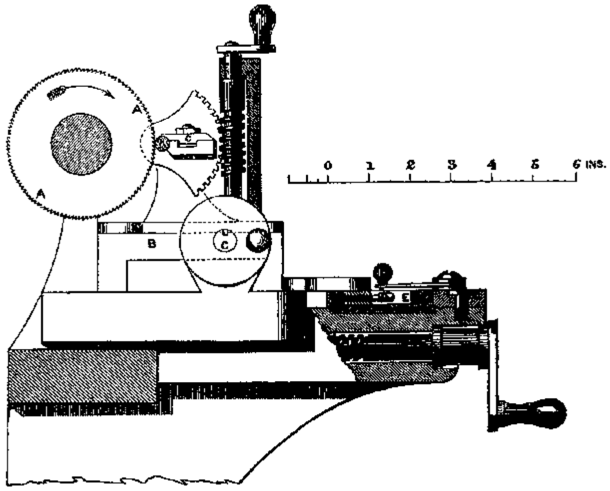
Hence a person putting a false bit into one of these locks will not only infallibly lose it at the very first trial, but will do so without gaining any information as to the nature of its inaccuracy; for as the gatings of the levers cannot be seen or felt, all that can be told about the action of a false bit is, that it has failed to open the lock. In fact, a counterfeit bit passes under the levers, and through the lock, just like the true bit; and it is only the stoppage afterwards met with of the bolt that indicates the failure of the false bit, which is by that time gone beyond recovery. Whatever amount of labor therefore, may have been spent on the fabrication of a counterfeit bit, this bit can only be tried once, so that no alteration can afterwards be made in it.



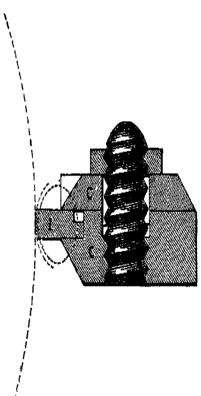


Figure 62

Nothing that can be inserted into the radial slot of the cylinder **c** through the aperture in the front plates can do any injury to the lock; and a charge of gunpowder inserted in that way would only blow out again at the orifice without damaging the lock, both the apertures for the key being merely blind holes with parallel sides.

For the manufacture of the bits for the keys of this lock a self-acting machine is employed, in which the height and width of the several steps in the bit are regulated by adjustments of very great accuracy, and admitting of an almost endless variety of figure for the bits. This key-cutting machine is shown in **figures 62 to 64**, and consists of a small circular saw **A**, running vertically, of the same thickness as each step in the bit **I**, which is brought up to the saw by the slide-rest **B**. The bit **I** is fixed in the holder **c**, which rocks upon a center so as to give the required curvature to the edge of each step in the bit when cut by the saw, as shown in the full-size section of the bit-holder, **figure 63**.

Figur

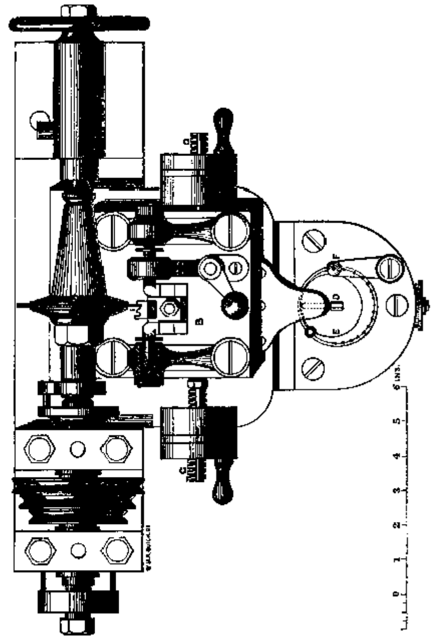

Figure 64

The adjustment of the depth of cut is effected by the setscrew **D** upon the slide-rest. Coming up against the eccentric ring **E** upon the bed of the slide-rest; this ring is turned round by hand, and set to sixteen different positions by means of the catch-pin **F** and the sixteen holes on the circumference of the ring, allowing of sixteen different depths of cut.

The lateral adjustment for the pitch between the successive steps of the bit is effected by the two bed-screws **G G** acting on the slide-rest **B**, having a dividing plate on the head, and such a pitch of thread that one turn of the screws traverses the slide-rest through the exact distance of one step in the bit.

The occurrence of any play or backlash is entirely prevented by having the screws placed one at each end of the slide-rest; so that by slacking back one screw through one or more turns, and then advancing the other through the same number of turns, the slide-rest is always held with perfect steadiness between them, filling exactly the space between the ends of the two screws.

The number of changes admissible in this key-cutting machine, if used for making keys for locks having six levers, is the number of permutations that sixteen terms are capable of when taken six together, which is upwards of sixteen millions. Some of these changes are so slight that too great accuracy of workmanship

would be required to make the locks accordingly; but of those changes that differ from one another so far that no lock could be opened by any other than its own key, more remain than could be used up by all the locks in the world.

The writer may observe that it was the study of the circumstances of the great gold robbery on the 15th of May, 1855, by Agar and his confederates (when two of the best lever locks were picked, and gold stolen weighing upwards of 200 lbs., while in transit on the South-Eastern Railway from London to Paris, packed in three sealed iron-bound boxes, enclosed in a bullion safe, secured by those locks), and of the various modes of picking locks, which led him to turn his attention to the achievement of what had been so long and perseveringly sought after, namely, an unpickable lock.

The principle of a detached bit has been previously tried, in so far as that locks have been made in which the bit of the key was deposited in the lock by unscrewing the key stem, and then withdrawn by screwing in the stem again. But inasmuch as the detached bit, even though it failed to open the lock in the case of a counterfeit key, could always be brought back again to the keyhole and removed, this admitted of a repetition of attempts with successive alterations of the one counterfeit key, without the certainty that any warning would be given by the lock of such attempts having been made.

In another still more complicated lock with a detached bit there were two keyholes, into one of which the bit of the key was put, and the stem being then unscrewed from the bit, was put into the second keyhole and turned round so as to close the first keyhole over the bit; a separate handle was then turned to work the lock, six separate operations being required for either opening or closing the lock.

Further, a kind of retainer has been attempted by so arranging the lock that, if any key was put in but the right one, it was held in the keyhole in such a manner that it could never be got out. In this case, however, if the false key would not open the lock, neither would it let even the right one do so, and it would be necessary to break open the door secured by the lock.

In the new lock here described, the special points that have been aimed at are the following:

Firstly, in no position of the lock is there any access to the

works from the outside through the keyhole. This access through the keyhole is more or less a defect in all other principles of lock, as it admits of feeling and manipulating the works for the purpose of getting information for picking the lock in the absence of the right key; whereas in the new lock there is no opening whatever at any time, except the two plain parallel recesses into which the key and the bit are fitted.

From the moment the turning of the lock commences both these recesses are effectually blocked up: the one for the bit being conveyed bodily away from the keyhole, and its place taken by the solid metal of the cylinder; while the other is completely filled by the key, which cannot be withdrawn except by turning it back to the original position.

In consequence of this construction, no injury can be done to the lock by explosion of gunpowder in the keyhole, the only openings from the outside being parallel at their sides, and not communicating with any portion of the interior of the lock; and the simplicity and solidity of construction are such that the revolving cylinder is made practically air-tight within its bearing. This effectually prevents all attempts to open the lock by picklocks, and leaves no alternative but the attempt to make a sufficiently accurate copy of the true key.

Secondly, as no clue whatever can be obtained from the outside of the lock respecting the key required, the attempts upon the lock are thus limited to the chance of obtaining a wax impression of the true key. The difficulty of making a counterfeit key sufficiently correct by this means for opening one of the best of the previous constructions of lock is very great; but in the new lock this difficulty is greatly increased by the fact of the levers remaining absolutely stationary while the stump enters the gatings in consequence of which the gatings are made so close a fit to the stump that an exceedingly minute error in the lifting of any of the levers is sufficient to prevent the lock being opened.

This extreme delicacy of construction can be carried out practically without objection in the new lock, because there is no possibility of putting a strain from the key upon the stump, so as to cause injury by forcing it at the moment of entering the gatings, for the only force acting upon the stump at that time is the uniform pressure of its own spring.

In addition to this source of increased safety, there is the

still more important circumstance that only a single trial can be made of each counterfeit bit; because, if carried forwards far enough to try its effect in opening the lock by passing the levers, the bit is inevitably lost by falling through the lock and inside the door. Thus not only is all chance prevented of a second trial with the same key, but the bit retained inside the door gives warning of the attempt having been made, and shows how near the counterfeit key has approached to the original.

The numerous cases that have occurred of attempts to open locks by counterfeit keys, such as the remarkable instance previously referred to, show that even with the most practiced hands it is next to impossible to make from a wax impression a key that will serve for opening a good lock the very first time it is tried; and the striking importance is therefore seen of this arrangement in the new lock, which prevents more than a single attempt being made with a counterfeit.

Thirdly, another advantage to be named in this lock is that the stem alone of the key is required to lock it, but it can only be unlocked by the complete key. The stem, therefore, can be left by the principal of an establishment for locking up by a subordinate; but the bit, which is the essential part of the key required for opening the lock, need never be used or seen by any one but the principal himself.

As the hole in the external door-plate for the stem of the key has a notch on one side only to admit the key stem, and the cylinder is prevented from making a complete revolution, the stem of the key cannot be withdrawn from the lock except when the bolt is shot; so that its absence from the keyhole serves as a proof that the bolt is shot.

Fourthly, one other advantage in this lock is its simplicity and solidity of construction. It contains no more parts than the simpler forms of lever lock having the same number of levers, and the total number of separate pieces in the complete lock is only sixteen. The principle of security, therefore, upon which the new lock is constructed, avoids entirely the complications and the delicate and minute class of work rendered necessary in other locks by the use of detectors and the other auxiliary contrivances employed for increasing the difficulty of picking.

Mr. Fenby exhibited, at a conversazione of the Institute of Civil Engineers, and at the meeting of Mechanical Engineers, specimens of his adytic lock, and showed its action both with the true key

and with counterfeit keys; and he showed by trial that the counterfeit failed to open the lock, notwithstanding that by means of the permutating cutting machine it had been made a much nearer approach to a perfect copy than was practicable in the best handwork from a wax impression.

He also exhibited the key-cutting machine employed for cutting the bits; and also a set of burglar's tools employed for drilling into the door of an iron safe sufficiently for breaking open or removing the lock, showing that the hold required for giving the cutting pressure upon the powerful drill employed for the purpose was obtained by a steel cross-piece inserted into the keyhole and turned at right angles, so as to hold across inside the lock; but in the new lock, as the keyhole had no opening into the lock, and only a slight shoulder on one side, no means were afforded for obtaining the required hold for the drill.

The following are the salient points of the discussion that followed the reading of his paper:

The Chairman remarked that the paper just read "gave a very excellent and clear description of the detailed working of the new lock, and he thought this construction of lock was a most valuable one, as affording real security against all fraudulent attempts. He inquired whether there would be any possibility of tampering with the lock by examining it upon the inside of a safe door, whenever the door might happen to be left unlocked.

Mr. Fenby replied that there was no means of tampering with the lock from the inside of the door, as the two keyholes for working the lock were only in the front face of the door, and the lock was all closed up on the inside of the door, excepting the hole through which the bit was allowed to drop out; but this would be useless for the purpose of tampering with the lock, as the bit dropped down a tube leading to the bottom of the door, through which no examination of the lock could be successfully made.

The Chairman inquired whether there was any provision against the bit being accidentally locked up inside the safe, in which case it appeared the lock could not be opened again.

Mr. Fenby replied that the owner of the safe must of course be careful after unlocking the safe to take the bit out before locking it again, otherwise there would be no means of opening the lock afterwards with that key. As a precaution, however, against any such accident, each lock was provided with three

bits, all duplicates, one of which would be kept in the pocket for use, while the two others would be preserved in a place of safety for the chance of any such contingency.

Moreover, in most of the safes fitted with these locks, the tube through which the bit dropped had been made of such a length as to carry out the bit on opening the door, dropping it into a smell tin tray outside the safe; and by this means the accidental locking in of the right bit was rendered impossible.

One of the advantages of the new lock was that the stem of the key was not required to be kept constantly in the possession of the owner, but it might be left in the lock, as the bit alone was the valuable part of the key; and as the bits were of such small size and convenient shape, a number of them might readily be kept in the pocket by a person having charge of a number of safes, without the inconvenience attending a large bunch of ordinary keys.

In the case of an attempt being made to open the lock with a counterfeit bit, the advantages of retaining the counterfeit inside the safe were not merely that the person attempting the lock was deprived of his instrument, while the proprietor immediately discovered the attempt upon the next occasion of opening the safe; but the retention of the counterfeit itself afforded the means of judging, by a comparison with the true bit, whether the attempt had been made altogether in the dark as to the actual construction of the lock, or whether it was likely that some clue regarding the true bit had been obtained by means of a wax impression or otherwise. In the latter case, the owner of the safe might think it desirable to have the lock taken off, and the arrangement of the levers altered, and a new bit made so as to baffle any further attempts.

Mr. W. S. Longridge observed that the inconvenience that had been alluded to with the new lock, of accidentally locking up the bit inside the safe, was no greater than occurred with an ordinary safe lock if ever the key was accidentally lost; in either case, unless the precaution was taken of keeping a duplicate in reserve, it would of course be necessary to have the safe broken open.

The Chairman inquired how the ideas had been arrived at of separating the bit from the key, and of preventing all access to the works through the keyhole, and also of retaining the bit inside the door after any attempt at unlocking.

Mr. Fenby replied that his attention had in the first instance been attracted to the subject of the picking of locks as a mechanical problem, and he had found that there had hitherto been no principle in lock making which could effectually baffle persevering attempts at picking. For although there were certain complicated constructions of locks, having many points of excellence, they had all yielded in time to the picking instrument in clever hands; and it must be remembered that any individual lock when once constructed remained stationary as regarded subsequent improvement, whereas the art of picking that lock was continually progressing towards success, with all previous constructions of locks, and it was clear therefore that the lock must ultimately be defeated.

He had been further stimulated in the investigation of this subject by the occurrence of the great gold robbery referred to earlier; and the circumstance which had struck him most forcibly in connection with that robbery had been that locks of the best make hitherto known had admitted of seven successive trials being made upon them without detection, each trial furnishing the information for further perfecting the counterfeit key, until the locks were at length opened.

These considerations had led him to the conclusion that two points were established and were required to be kept in view for the construction of any lock that should be really secure against fraudulent attempts. The first point was that wherever a man could get instruments into the lock he could ultimately solve any problem laid before him by the maker of the lock, as the lock when once made could be tried any number of times if an instrument could be got into it at all. Hence he had concluded that it was requisite for all access to the interior to be cut off, so as to preclude all possibility of getting a pick-lock in; and this was accordingly accomplished by adopting the plan of separating the bit from the stem of the key.

The second point established was that it was necessary to prevent the possibility of making a succession of trials with the same counterfeit key; and it had then struck him that, if the bit of the key were arranged to drop inside the safe in unlocking, there would be no means of going on gradually improving and touching up the counterfeit from the results of previous trials, as the false bit would be irrecoverably lost in the very first attempt, without furnishing any clue whatever as a guide for alteration in a subsequent trial.

The first lock that he had invented for meeting the requirements thus pointed out had been made with a solid block having a tunnel through it, but involving the same principle of retaining the bit of the key and keeping the levers inaccessible from the outside. Subsequently, however, he had abandoned that construction and produced the new lock shown in the drawings, having the revolving barrel with radial slot.

The Chairman proposed a vote of thanks to Mr. Fenby for his paper, which was passed.

CHAPTER FOURTEEN: Fenby's Patent Stop-Lock

MASTER EXHIBIT LIST

This lock has been designed with a view to doing away with several weak points in the construction of lever locks.

The introduction of the moveable stump by Mr. Hobbs in order to defeat picking by the tentative method of applying pressure to the bolt, so as to cause binding between the stump and the levers, was a great advance in the art of lock-making.

The moveable stump, as so constructed, was, however, open to this objection, that while sufficiently delicate and certain in its action to render picking very difficult, it was at the same time, through the smallness of its parts, resulting from the confined space available for its action, unsuited to withstand any amount of force applied to push back the bolt.

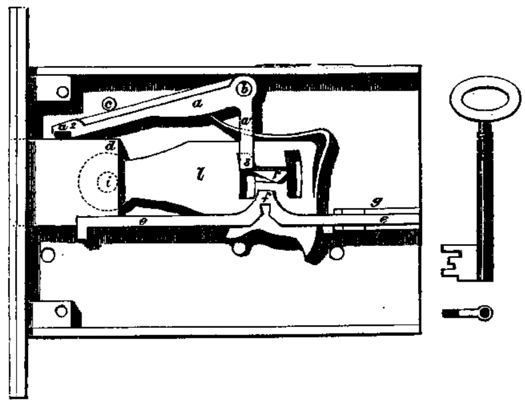

Figure 65

In the look under notice the stump **s** is formed in the solid on the shorter arm **a**^{1} of a cranked lever or oscillating stop **a**. This stop **a** works on the steel pin or center **b**, which latter has a bearing in both plates of the lock. At the end **a** of the stop a is a recess formed to fit the corner **d** of the bolt head. **C** is a stud limiting the range of **a** in an upward direction, so that when in its normal position the stop **a** may just clear the bolt-head, as shown in **figures 65**, **66**, and **67**.

The tail of the bolt, instead of being in the form usually adopted, is formed of the bar **e** set on edge so as to reach from the back to the front plate of the lock, completely dividing the lower part, in which the keyhole lies, from the upper, in which the main parts of the works are placed.

This bar **e** works between the guide pieces **g g** so that in whatever position the bolt may be, the division of the lock into two chambers is complete. At **f** is the recess in which the key acts to move the bolt. The levers **l** turn upon the pin **i** formed in the solid of the bolt-head. The part of each lever on which the key is to act passes through a slot or recess in **e**, the parts **h** and **h**^{1} of the levers being struck to the arcs of circles, having their centers coincident with that upon which the levers turn at **i**.

As it is not possible to lift the levers out of this slot in the bar **e**, and further, as the levers and bolt move together in a longitudinal direction, the movements necessary to locking and unlocking open no communication between the upper and lower chambers of the lock.

The springs of the levers are formed out of the solid metal of the levers themselves, and are thus not liable to that displacement which so often occurs with separate springs, nor to the corrosion by oxidation incidental to steel springs. They are cut round the corner, and down the front of the lever, to gain greater elasticity.

In **figure 65**, the lock is shown with the front plate removed, and the works as they stand when unlocked. **Figure 66** is the same, except that the works are shown locked, and the back plate removed instead of the front. **Figure 67** shows the *front* view of **figure 66**. **Figure 68** shows the result of any attempt to pick the lock by pressure.

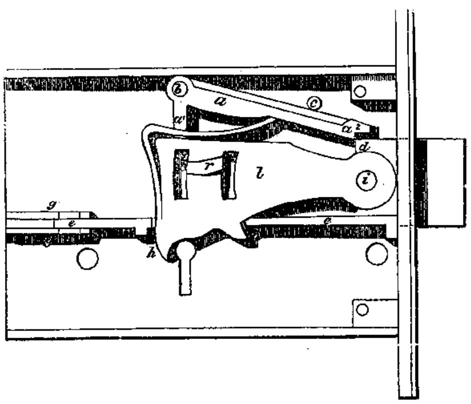

Figure 66

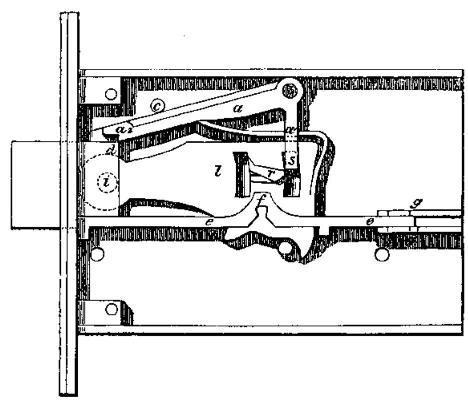

Figure 67

The lock being locked, as shown in **figures 66** and **67**, it will be seen that the stop **a** just clears the angle **d** of the bolt-head.

Further that the gatings **r** of the levers **l** cannot pass the stump **s** unless the levers be so lifted as to coincide with each other and the stump. The stop **a** being held up by a very light pressure from the lever springs, a small force applied to the stump **s** is sufficient to upset its equilibrium, and bring down its end $\mathbf{a}^2$ upon the bolt-head at **d**, as shown in **figure 68**.

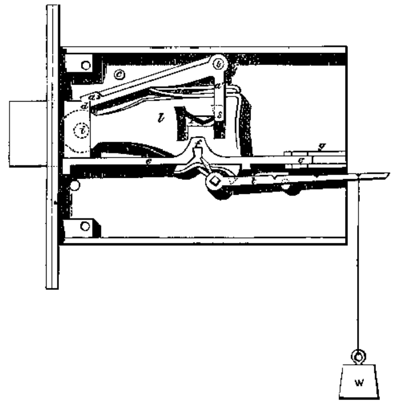

Figure 68

This occurs whenever an attempt is made *to "feel"* the stump with the levers; and not only does the stop **a** free the levers from all pressure, and so preserve them and the stump from injury, and the lock from being picked, but it also forms a strut for securing the bolt: in fact, no violence short of that necessary to shear the pin **b** can make the bolt yield.

The drawings show a mortise lock, but the improvements shown are universally applicable in the construction of locks of all kinds.

For the manufacture of these and other locks, and kindred articles, Messrs. J. B. Fenby and Co., engineers of the Liverpool Works, Birmingham, have put up, from the designs of their managing partner, Mr. J. Beverley Fenby, an experimental set of machinery, almost entirely self-acting, and calculated to turn out large quantities of the component parts of locks and other articles with extreme accuracy and rapidity.

The whole set works on the interchangeable system, as already in use for military small arms. It is not, however, to be supposed that, because the parts of the locks are interchangeable, one key will open several locks, such a source of insecurity being guarded against by the permutating key-cutting machines invented by Mr. Fenby. These machines give complete command over the making of keys, whether it be required to make a comparatively unlimited number, all differing from each other, to make a number alike, or to make sets with master keys. Atmospheric and hydraulic pressure also plays an important part in shaping many of the parts of the locks.

NOTE UPON IRON SAFES

AT the conclusion of this work upon locks it will not be out of place to make a few remarks upon the degree of real safety that attaches to what are commonly called "safes," and to point out in a common-sense way what are the chief dangers that these may incur from depredators (whether burglars or in times of public anarchy and violence), and what are the main conditions to be relied upon for safety; assuming that, by one or other of the constructions pointed out in the preceding pages, the *lock* of the safe be such as to be practically unpickable, and that carelessness shall not have placed the true key in the possession of the thief.

There can be no doubt upon the mind of any mechanic or engineer, thoroughly acquainted with practical working in metals, that a good deal of what has been brought forward and affirmed, both by safe-makers and by burglars themselves (turned approvers), as to the wonderfully-ingenious devices resorted to by the latter, by which, if we were to believe it all, nothing in the shape of steel or iron can possibly withstand ultimately the redoubtable powers of these people, is simply fiction—imaginary ingenuity utterly impracticable if tried.

Such, for example, is the notion of its being possible, by an ounce or two of gunpowder exploded in the interior, to so blow asunder and dislocate the parts of a well-made safe lock that the bolts shall then be easily got loose, or that a steel-plated safe which resists the drill can be softened "by the blowpipe." And just as absurd are some of the wonderful pieces of ingenuity by which some of the burglars' actual devices are supposed to be met and frustrated; as, for example, one for which we believe a patent has been obtained, consisting in filling-in the hollow space between the inside and outside plates of the safe with cast-iron bullets left loose. These might, no doubt, break a flat-stemmed drill after that had pierced the outer plate, but could have no effect whatever upon a round-shanked drill, such as one of the ordinary American spiral, or teredo-pointed drills.

That there are some methods of violence still untried, and yet at the command of the burglar who dares to risk a tolerably loud noise of explosive agents, is well known to skilful mechanical engineers, and for obvious reasons it would be unwise that we should give any information as to such; but the real practical and too-often effectual methods of the burglar limit themselves almost entirely to the use of the succession of steel wedges, followed by the powerful steel-pointed pinching bar, or bars, to the forcing or prizing-screw, and to making more or less way for

this by cutting out beforehand by the pin-drill.

A safe, to be safe, must be so circumstanced or so constructed, or both, that it should be able to resist the best efforts that can be made by these methods for several hours; perhaps we might say as much as thirty to thirty-six hours—viz., from Saturday night to Monday morning.

Now we hesitate not to say that the unsafeness of "safes" arises not from any structural difficulty whatever, but almost always from the parsimony and ignorance of those who purchase and employ them. Safes, like razors, are made to sell, and if the public demand is for cheap safes, such as we see every day advertised in the newspapers, it was sure to have been, and is, met by a supply of things called safes which are utterly unsafe. The great mass of the showy green and gold gewgaws that one sees in the safe-shop windows, with flaming testimonials as to their fire and burglar-proof powers, are simple shams: a genuine safe could not be made at their prices.

The very first condition to constitute a genuine safe is that it shall have an ample mass of metal--i.e. not of cast-iron, but of wrought-iron, or best of steel, all around it; and especially that the margins of metal all round the door shall be of such huge and surplus scantling that no amount of wedging, by construction possible, should be able to bend any one side sensibly.

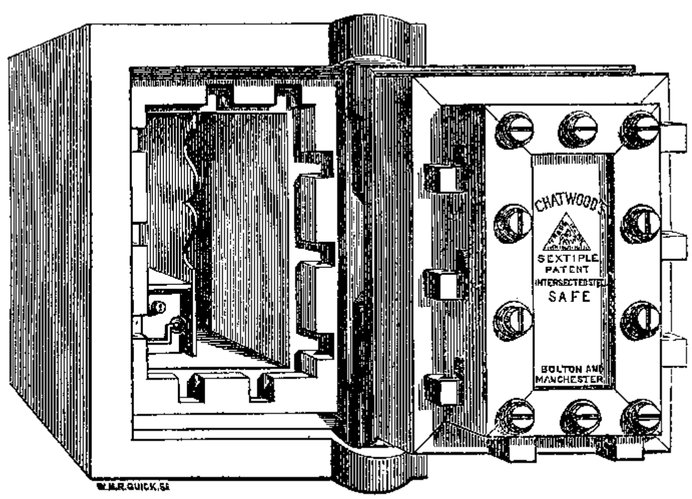

Figure 69 Chatwood's Safes.

The next is that the workmanship of every part of the safe be first-class: not that there be merely a molded door with a showy

lock and a trumpery brass-plate upon it, but that every corner and joint of plate with plate in sides and back be effectually united and jointed in the best manner, and that the fitting of the hardened edges of the door shall be like those of a valve, and not even let a watch-spring be got in between. If these obvious conditions be observed, and that the safe itself be properly posited in the premises, it will be found, even with ordinary forms of construction as to doors and bolts, but with a really unpickable lock, a very hard nut for the best burglar to crack.

But much more may be effected without any serious increase of cost. Several forms of safes are now made, the rabbets of the doors of which are so formed that it is almost a physical impossibility to get any wedge, however thin, to drive in between the door and the frame. This is effected in Chatwood's patent safes (of Bolton and Manchester), as figured above, by making the door rabbets in cross section curvilinear so that even if the fit be not so perfect but that the edges of a very thin wedge can still be inserted, it yet cannot be driven, for as it goes forward, it must become curved, and if soft, so as thus to bend, the thin steel will not bear the severe strain of driving, but if hard, it breaks off into short bits close to the entrance.

In addition to this Chatwood's (and we believe other maker’s) safes have bolts so constructed, as seen in the **figure 69**, that they *hook* or lock into the bolt recesses in the frame in such a manner as to hold the opposite sides of the frame together, so that, independent of its own proper stiffness, it cannot be bent anywhere, unless by tearing asunder the end on the iron bar constituting each cross-bolt. The bolts, in fact, not only secure the door (as in ordinary) from opening, but secure the door and frame together. With such a safe, if the owner will only provide a proper position for it in his premises, he may rest pretty easy in mind.

Safes are very commonly stood upon a wooden floor, or made to form part of a wood-framed bookcase, or press, or stand in a recess. Often they are comeatable all round, and even underneath, with nought but an inch board below them, and almost always they are left with the front door freely and fully exposed, and with ample and convenient room left all round. This for two or three workmen to manipulate the safe as they may.

Now the only real conditions of safety are that the iron safe should be bedded into brickwork set in Portland cement and sand;

or, what is much better, in hard granite or gritstone masonry, bedded in like manner. Without this be done, a fire-proof safe is simply a delusion; constructed how it may be, it is only a crucible of more or less badly-conducting power, in which, after a time longer or shorter, deeds, bank-notes, documents, etc., will be calcified, and coin or jewelry melted, and gems flawed and destroyed.

We say this in the full face of the delusive so-called "fiery ordeals" to which many of the so-called double-cased fire-proof safes are alleged to have been for hours exposed. The safe should always be embedded in masonry, and rest upon that in such a way that it cannot get undermined by either fire or burglars.

Whenever the premises admit of it, the door of the safe itself should be set back ten or twelve inches from the face of the wall in which it is embedded, and an outer door, flush with the face of the wall, should be provided of iron, with a good lock and multiple bolts. The door of the safe should open to the right; and if so, the outer door should open to the left; and neither should open more than square to their position when shut.

No one but a practical workman or engineer can have an adequate notion of the extent to which any mechanical operation upon the door of a safe thus circumstanced is hampered by its being set back into the wall, and with an outer door that even when open, cuts off all ready manual access to the inner door from one side.

When premises are constructed, as they should be for all banks and bullion merchants, jewelers, etc., having special regard to a safe as an indisputably secure depository, then the safe should be completely iron or steel cased, and embedded in hard stone masonry (we shall not here go into additional special precautions against the remoter effects of fire), covered in with a strong fire-brick arch, and with nothing but the solid ground below.

The door of the safe should only be approachable through an iron or stone-lined passage, just the size of the safe-door, and no more. This should be some feet in length, and have an outer double cased steel door, or perhaps that and an intermediate iron falling-door or portcullis, between the outer door and the safe-door. With a safe-door so circumstanced, even supposing both these outer doors forced and open, it is almost impracticable for even a single workman, however agile or adroit, to perform any mechanical operation whatever upon the door, least of all upon its surrounding rabbates. These are so close to the solid granite

walls, starting out at right angles from the rabbate all round, that he has no room to do anything; and to get a prizing-bar at the door-rabbate or even to get a second man to assist the first in any way, is impossible, simply for want of room.

The whole of the doors and all the surfaces of such passage should be painted a dull, lustreless black. No one who has not tried it, has any idea of the difficulty of illuminating such a black passage, by even several candles, sufficiently to perform any delicate mechanical operation; and good light is essential to the safe-breaker.

In banks there is no better plan than has been here now adopted of making the iron safe a great cube, with the door at one side, placing the whole safe with its bottom resting upon the stem or plunger of a hydraulic press, the cylinder of which is fixed in the bottom of the pit in the solid earth, of a size capable of enabling the whole safe to be bodily lowered down into the cavity at the end of the day's work, and pumped up again out of its hiding-place the next morning.

The lever of the hydraulic pump is taken away, and the socket into which it fits is plugged, and the plug locked into its place, and then the pump, situated in a recess in solid masonry, is itself locked up. The top of the safe itself, when it has been lowered to the bottom of its chamber, stands ten or twelve inches below the floor-level of the stone floor, and a pair of iron doors is then closed over it and locked down.

A safe executed in this way, though requiring a considerable expenditure at first, if well done, might bid defiance to anything almost, even unlimited gunpowder, for some days. The only addition of safety that almost could be conceived would be that adopted at the bullion vaults of the Bank of France in Paris, where these, situated in casemates two stories under ground, are only approachable by one narrow, winding staircase, which can be itself, in case of emergency, rapidly rendered useless, and the cylindrical well in which it is placed filled up with about thirty feet in depth of water, which cannot be pumped out until a continuous supply be shut off by distant means only known to one or two trusted employee.

Since this revision has been in type the great "safes” contest or wager of battle between the rival safes of Mr. Herring of New York, and Mr. Chatwood of Bolton, for £600 a side, has come off, at the International Exhibition, Paris, Mr. R. Mallet and Mr.

Robert F. Fairlie, C.E., being the representatives of the English interests upon the occasion.

The result, which, owing to the conduct of some of the parties concerned, assumed an unpleasant and incomplete form, may be found detailed fully in a pamphlet published by Tinsley Brothers, London. It is referred to here because, although no decision of the wager made could be come to, the facts ascertained are of great interest and importance as respects the proper construction of safes. They show conclusively that an effectively constructed door and jambs is really the one thing needful to absolute security, provided the safe itself be built up, as we have urged, into masonry.

They also show that there are good grounds for doubting that the American (Herring's) "safe within safe" construction, with a thick mass of so-called fire-proofing powdery composition between them, is at all as protective against mere violence and the persevering use of wedges, as Chatwood's simpler but far more effective construction, especially of his door and jambs. If one of the latter safes, wholly of steel plating, be fairly embedded into masonry, and another outside flush door of his construction, with curved rabbates and hooking locking bolts, be supplied to the masonry open itself, it is scarcely an exaggeration to call such a safe "Invincible," so far as anything that burglars, in any civilized place in Europe at least, can effect.

LONDON: Simpkin, Marshall, and Co.

The First Edition was published in 1856

The original work was edited and rereleased by Marc Weber Tobias in 2002, in conjunction with the publication of Locks, Safes, and Security, Second Edition.

Chapter 19 The various kinds of Locks and their Comparative Prices

PREFACE to the FIRST EDITION

The substance of the chapters in "Fire and Thief-Proof Depositories" was Dublin, and in the town of Belfast. But for ill health, they would have been delivered in some of the cities and towns of England.

Having been repeatedly requested to publish it, and the press having given it a complimentary and approving notice, I have done so, in the hope that it may throw some light upon a subject very imperfectly understood, not only by the general public, but by those whose interests ought to make it a subject of deep

consideration.

It is almost incredible in these days, when the arts and sciences are lectured upon in almost every Provincial town in the Kingdom, when the artisan is taught not only that such a result follows a certain law, but the why and wherefore, the cause as well as the effect, that persons of general intelligence and scientific knowledge should place their valuable convertible property in a cast-iron safe, with a box of wards for a lock, expecting that it will preserve such contents from destruction by fire and abstraction by thieves.

That others for the sake of saving a few shillings in the primary cost of a lock for the safe keeping of their property in an iron safe or other receptacle, will purchase one that can be readily picked with a quill or a skewer, not only by the accomplished burglar, but by any ordinary mechanic or intelligent artisan, as well as by the amateur lock-picker.

As there are no works in our language, except a few pamphlets and a rudimentary treatise on the subject of locks, I have added the chapters on locks and keys, in order to make this treatise as complete and useful as possible.

I am especially indebted for many extracts to Mr. Granville Sharp's "Prize Essay on Practical Banking," Mr. Chubb's paper "On the Construction of Locks and Keys," and the **"Rudimentary Treatise on the Construction of Locks,"** by Messrs. Tomlinson and Hobbs, works of such an interesting character that they should be read by all. Other general works have afforded me considerable information.

Mr. Chubb, in the work before-named published in 1850, says, without intending in any way to depreciate the numerous inventions for the improvement of locks (many of which possess great merit), "it will be sufficient to describe particularly the three principal locks which are well known and generally appreciated, viz., Barron's, Bramah's, and Chubb's."

In Messrs. Tomlinson and Hobbs' work, published in 1853 (and 1868), the only principal modern locks described are the American inventions. It will, therefore, be seen that the improved locks which were the fruit of the lock controversy produced by the Great Exhibition of 1851 have not been described, with two or three exceptions, in any work hitherto published.

Many of these inventions possess considerable merit, and for security are far superior to nearly the whole of the locks known prior to the year 1851.

Portions of the first part, which is written in the first person singular, may be considered as somewhat egotistical, but the extraordinary opposition which the author experienced, and the strange course of conduct adopted towards him in certain instances by the agents and representatives, and in one case by the foreman of a competitor in the same trade, rendered such a tone imperative, and it is hoped will be deemed a sufficient excuse for it, as such parts were really written in self-defense.

As manufacturers are not expected to be also authors, and as the subject was beset with considerable difficulty in point of interest, especially as regarded scantiness of materials for illustration, I felt bound to spare no pains in acquiring all the available information that could be obtained to render it at least as clear and intelligible as possible.

How far I have succeeded it is for my readers to determine; but whatever may be thought of this humble work, thrown off during the intervals of absorbing avocations, none, I am sure, will feel disposed to question the importance of the subjects treated of.

GEORGE PRICE

PREFACE to the SECOND EDITION

George Price wrote an extremely comprehensive work on the history and development of locks and safes during the time of the Great Exhibition in London. This was a period of significant advancements in the design of locks, safes, and vaults. His treatise provides a rich insight into the state of security technology of his day. When I was first introduced to this work by Horace Smith in England, I was fascinated by the chronicle of historical development of the forerunners to modern locking systems.

It was immediately obvious that this work should be updated and integrated into the Electronic edition of ***Locks, Safes and Security***. Although I have taken license to change some of the traditional English verbiage in order to enhance readability in our modern world, I have also attempted to insure that the

excitement, intrigue, and ingenuity of the era and its pioneers remains intact.

The Electronic Infobase Edition of ***Locks, Safes, and Security*** allows the flexibility to link and combine the information within these two books with a third by Alfred C. Hobbs. I hope that this allows the reader to gain a deeper understanding of how locks and safes were developed, and the difficulties that were encountered by the craftsmen in Wolverhampton, Willenhall, and throughout Europe and America. Links to other areas of the Infobase are designated by **[**brackets**]**.

One of the video segments that can be found within this infobase was shot in London with Jeremy Bramah, a distant relative of Joseph Bramah. I believe that the reader will find that this provides more insight into the era of the Great Exhibition and complements the work of George Price.

Mr. Price provided a timeless and valuable chronicle of events that ultimately resulted in the security principles and devices of the twentieth century. I hope that the availability of his work furthers an understanding of the locksmith profession, and an appreciation of the difficulties in bridging the forty centuries from the first Egyptian lock, to the modern highly technical world of security and its practitioners.

MARC WEBER TOBIAS

BOOK ONE: Locks and Safes

CHAPTER ONE: Introduction to Locks and Safes

I have frequently been asked for advice regarding safes that are suitable for specific uses and situations, and for information regarding many facets of their design and construction, including:

- **The thickness of the plates forming the body and door;**
- **Upon what principle they are made fire-proof;**
- **How long they will resist fire;**
- **Whether the locks are resistant to picking and powder-proof;**
- **If the door will resist drilling;**
- **The best place to fix them;**
- **Other technical questions.**

I conceived that a treatise giving a short history of the Iron Safe Trade would be of benefit. I determined that this treatise should include a description of all the patents taken out in connection therewith, especially of those improvements recently introduced by myself, as well as the details of their construction, and illustrated by diagrams and engravings.

I believe that such a book would be well received to those in want of current information. The details are considered essential to the peace of mind and comfort of not only the banker and merchant, but of every trader who has books to preserve, or the householder who has cash and plate to protect.

The public can benefit as well, especially when one considers the immense value of the precious metals, specie, bank-notes, deeds, and commercial books already entrusted to the custody of iron safes, boxes, and strong rooms. [See **Chapters 1**, **2**, and **33**.]

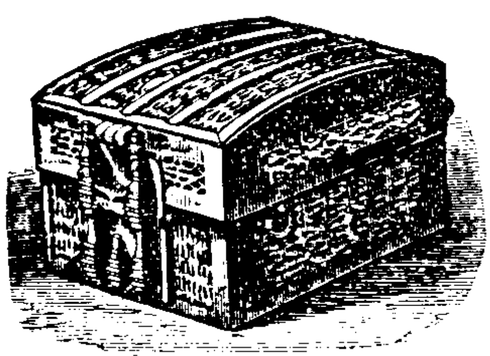
Mr. Granville Sharp, in his "Prize Essay on Practical Banking," says, in the Article on Safes, at page 315, "For the purpose of awakening attention to the importance of locks and safes, it may be suitable here to quote a passage from the Bankers Magazine, for April, 1845:

'In a country where a large class subsist by robbery, and where the means of effecting it securely is the constant study of skillful and ingenious thieves, the only means of baffling them, and of protecting the ordinary depositories of valuables from their felonious attacks, is to call in the aid of the greatest mechanical skill with respect to locks and fastenings, and to exercise unceasing care and vigilance.

[See **Chapter 38**, regarding casing and surveillance.]

The bank robberies during late years show that they have been planned with extraordinary sagacity and have been effected with a

degree of skill which proves that they are not undertaken by ordinary thieves. The large amount of money which the house-breakers are confident of obtaining in the case of a successful burglary at a bank, induces them to act with a degree of skill and caution proportionate to the expected booty; and it is for a bank is seldom heard of.



When **'a set'(443)** is made at a bank, every information is in the first place sought for by the burglars of the means of security adopted, and it has been ascertained that many weeks and even months have been occupied in this manner.

Attempts are made to tamper with the servants, and an acquaintance is formed, if possible, with some of the female domestics. If, upon inquiry, it is found that the means of security are so numerous and inviolable as to give no chance of success, the matter is quietly dropped.

However, if any opportunity presents itself, no time is deemed too long to wait for the proper moment when the bank may be entered, the misnamed safe or strong room be opened, and a clean sweep made of all the convertible securities and money it may contain.'

[See **Chapter 8**, on false keys and impressions of keys.]

This was exemplified in the bank robbery at Glasgow some years since. When the Dorchester Bank was robbed some years ago, the burglars were in the house ninety-two nights before they succeeded in opening all the locks, which they did by fitting false keys that would unlock and relock them."

CHAPTER TWO: The Early History

of the Iron Safe Trade

[See **Chapter 1** and **33** on the development of safes, and **Chapter 13** on warded locks.]

Fire-proof Iron safes and chests are of modern date not having been introduced until this present century. Our forefathers were satisfied to place their valuables in an oak chest secured by one or more locks on the front. If they did not utilize that they would have a special room made of brick or stone. The entrance to that room was secured either by an iron door or solid wood door which would have a common warded lock, or a lock without wards, and not uncommonly just be padlocked using a hasp and staples.

The most interesting specimen of the oak chest is the celebrated oak chest in which the crown jewels of Scotland were deposited in the year 1707. The lid was secured by three locks. These locks were thought to be so intricate and secure that no common locksmith or mechanic could open them. In 1818 the keys to these locks had been lost so the lid had to be forced open doing great violence to the lid. In reality these locks could have been picked with a skewer and thereby this ancient relic could have been saved from such unhallowed violence.

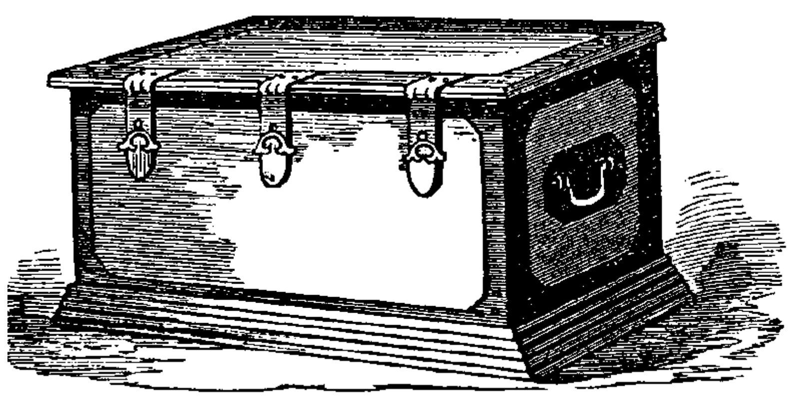


Figure 1. The Oak Chest

Many of these oak chests are still in existence and in a state of perfect preservation. They are prized for their antiquity and the fine carving that usually adorns them. The locks upon these

chests are also interesting. These are very simplistic locks and many may wonder how these locks and the chests they secured kept thieves from breaking in and stealing the contents.

The answer is that if the locks and chests were simple and made of wood, the thieves who would seek to gain access were also simple and had only crude tools with which to accomplish their purpose. In those days, the oak chest was quite as safe as the iron one is now. The strength of the chest itself would generally resist violence, while a lock of the most simple construction afforded sufficient security.

The first examples of the manufacture of iron safes or chests are the foreign coffers. The one illustrated below is 35" long, 21" wide, and 23" deep. It is made of sheet iron strongly riveted to hoop iron crossed at right angles on the outside. It has strong handles at each end, with a multiple lock, which throws eight bolts inside, and it has two doors at the back and two bars and staples for padlocks outside.

The whole of the iron composing it has been hammered and hot rolled, which circumstance goes far to prove that the date of its manufacture must have been before rolls were introduced into the country in which it was made. The plate covering the bolts is beautifully pierced and chased, and bears the date 1793 with the initials "C.H.".

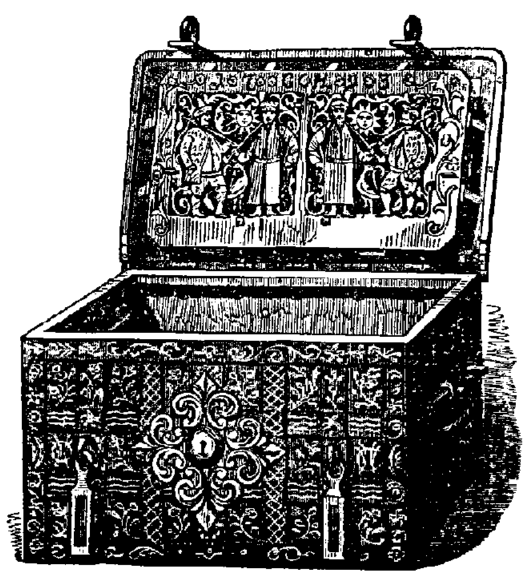

Figure 2 Foreign Coffer; a container utilized to store money

Another peculiarity about this coffer is the escutcheon over the keyhole in the lid. This has to be moved half round with a turn-screw and then it springs up. The key is then inserted, and with the turn-screw put through the bow for a lever. The lock then opens.

Another specimen is known in Paris by the name of the "Strong German Coffer". Reaumer says, "Nothing is wanting on these coffers on the score of solidity. They are made entirely of iron, or if of wood they are banded both within and without with iron, and can only be broken open by very great violence. Their locks are almost as large as the top of the coffer and close with a great number of bolts."

The spring attached to each bolt, though of such rude manufacture, is as effective as the best constructed of the present day. These coffers, taken as a whole, are creditable productions for that period. Every part was made by hand labor. Machinery was unknown.

These were an improvement upon the oak chest, as regards both the material of which they were composed and the locks by which they were secured. Their problem lie in the fact that the locks were easily "picked". But that notwithstanding these are the root from which all the improvements introduced up to the present time have grown.

It is my belief that cast or wrought iron safes were not made in this country before the present century. If they were, they must have been considered curiosities. They were certainly not in use for commercial purpose, and the possession of them must have been confined to a very few.

Cast iron chests have been made for many years at Coalbrookdale, Birmingham, Wolverhampton, and at some other places in England. Wrought iron safes were first made in London, and the trade was confined to the metropolis until within the last twenty years but are now made in other parts of England.

CHAPTER THREE: On Fire-resisting and Thiefproof Safes, and the Specifications of all the

Patents in Connection Therewith

The making of iron safes that are fire-proof does not appear to have been thought of until about the year 1834. As can he seen from the following list of patents, Mr. Marr was the first to introduce the improvement:

1. **William Marr, London, February 13, 1834.**
2. **Charles Chubb, London, May 13, 1838.**
3. **Thomas Milner, Liverpool February 26, 1840.**
4. **Edward Tann, Edward Tann, jr., and John Tann, London, November 25, 1843.**
5. **William Milner, Liverpool, March 3, 1851.**
6. **George Price, Wolverhampton, January 31, 1855.**

The first idea that presented itself to the mind of the manufacturer was to use a substance in the chambers of the safe that would retard the transmission of heat or neutralize the transmission of heat. This idea was adopted by Mr. Marr and he stated:

"My improved inner fire-proof case within which any combustible property may be placed, has a lining or covering of mica or talc, split into very thin lamina, and fixed to sheets of thin paper by gum arabic, and in that state is used to line or cover the two surfaces of the metal plates that form the inner fire-proof case."

"The space formed between the two surfaces of mica or talc should be completely filled or packed full of any suitable non-conductor of heat. The substance or compound represented in the drawing annexed to the specification is burned clay and powdered charcoal; but the chambers may be also, and with equal advantage, filled with dust or very small particles of marble, porcelain, slightly burned clay, etc., or any other suitable non-conductor of heat, either natural, artificial, or compound; and which being applied and combined with my improved lining or covering of mica or talc will assist in keeping it spread and stationary over the surfaces of the plates that form the inner fire-proof case."

Mr. Chubb, who secured the next patent, says, in his specification:

"My invention consists in applying tow or three internal linings of iron plate to the receptacle, one lining within another, leaving narrow spaces between each lining, and filling up those spaces with some such slow conducting, materials as will retard the transmission of the heat such as baled woodashes or charcoal, fragments of earthenware, pottery, tiles or bricks or sand-stone, broken small and rammed into such places, or coarse sand or small gravel sifted, or fragments of slate put in edge-ways, or other slow conducting material, to be applied in the shape of grains and powder. The non-conducting materials may be put into bags or cases made of cartridge paper, and put into the spaces. The materials may also be put into metal cases."

The reader will most likely smile at the simplicity of these specifications; but the early efforts of most inventors have generally been of a similar character.

{See **Chapter 33**, Development of fire safes.]

Thomas Milner received the third patent in 1840. It was described as:

"Construction, forming, or manufacturing boxes, safes, or other depositories, of an outer case of iron or other metal, or material, enclosing one, two, or more inner cases, with spaces or chambers between them, containing an absorbent material or composition, such as porous-wood, dust of wood, dust of bones, or similar substances, in which are distributed vessels, pipes, or tubes, filled with an alkaline solution or any other liquid or matter evolving steam or moisture, the tubes or vessels bursting or otherwise discharging themselves on the exposure of the box or other depository to heat or fire, into the surrounding absorbent matter, which thus pervaded with moisture, and rendered difficult of destruction, protects the inner cases or boxes and their contents."

The specification states that the inventor does not claim the making boxes with compartments filled with non-conducting substances for the purposes of resisting fire, "as that has been done before;" but he claims:

"The introduction or application of the combined effect in chambered boxes or depositories of the materials kept humid in the space surrounding the innermost box and its contents, without in any way being confined to the materials or liquid employed, or

to the manner in which it may be distributed or arranged in order to introduce the desired effect."

This unquestionably was an improvement far in advance of the previous ones, and is the principle upon which the majority of present day manufacturers make their chests and safes fire-proof.

But in 1843, Messrs. Tann took out the fourth patent. This fourth patent was founded upon the same principle, but effected in a simpler and different means. Their invention "consisted in forming the chests with triple bodies, one within the other, leaving spaces between the bodies, and filling up such space with the following compound: ground alum finely sifted, and Austin's cement or gypsum, finely sifted.

Either of the two latter substances were mixed with the alum, and heated to liquefaction in an iron pot, stirring the mixture carefully during the process. The mixture was then poured into an iron tray to cool. It then turned into a solid which was coarsely pounded when required for use."

This mixture the patentees prefer; but "any non-conductors of heat may be used, and for alum may be substituted sulphate of potash, murate of ammonia, borax, impure potash, nitrate of soda, soda in cake, pearl ash, or any of the known alkalis."

The principle having already been patented by Milner, in 1840, he considered Tann's method an infringement, and commenced an action against a Mr. Harrison, of Liverpool, who was selling Tann's safes and boxes, and advertising himself as the sole proprietor of the same. This case went to Court on June 23, 1851. A verdict was rendered in favor of the plaintiff, Mr. Milner and against the defendant, Harrison.

But this did not deter the defendant, Harrison, from continuing to sell Tann safes and boxes. So Mr. Milner applied for an injunction to restrain the defendant, Harrison, or any of his agents, servants, etc., from making, using, vending, etc., during the remainder of the term mentioned in the Letters Patent granted to Mr. Thomas Milner, regarding any boxes, safes, or other depositories that were made in such or the like manner, or on the same or the like principle, or in anywise counterfeiting, imitating, or resembling the said invention."

On August 2, 1841 the injunction was made perpetual against the defendant, Harrison and any of his agents, or makers, or any

others using such materials for the life of Mr. Milner's patent. Mr. Milner's patent did not expire until 1854 and he enjoyed the sole right during this term to exclusively manufacture and sell safes using the above principle until that time.

The Messrs. Tann, were compelled to relinquish their invention, and in their disclaimer, stated, that "having in their specification claimed the construction and adaptation of compound and double or triple bodies or cases placed one within side the other in succession, leaving spaces between the contiguous bodies, and closing and filling such spaces with the heat-resisting composition therein described, and having since learnt that that part of the invention is not new, they disclaim:

"Making iron rooms, safes, etc., with separate spaces between the contiguous bodies;" also, " they disclaim the use of muriate of ammonia, impure potash, nitrate of soda, soda in cake, pearl ash, or any other of the known alkalis."

In other words, they gave up the fight and ceased making safes and boxes based upon those principles. Mr. Milner was the victor and to the victor went the spoils. That being the sole right to manufacture fire-proof safes using the above principal.

The fifth patent, by William Milner, (1851) was for: "closing the door of safes and boxes by means of a continuous bolt or bolts on all sides of the same, extending or expanding into suitable continuous grooves, rebates, or recesses, formed within the front of such safe or box," which he terms "flame protectors." Also "to coat or cover the inside of the outer plate of the safe with a preparation of pulverized quartz, or other similar infusible material, mixed with a small proportion of hardwood dust, to be made into a cement, applied wet and then dated, for the purpose of more effectively resisting the action of intense fire in the interior of such safes."

This invention was the most useless of any of the developments, either before or since introduced. Flame always follows the direction of the air, it could not possibly get inside the safe or chest without first making a hole in some other part to cause a draught.

The final patent, dated January 31, 1855, by George Price contained six claims. These included:

- ***Painting internal surfaces to prevent rust;***

- **Case-hardening of barrier materials;**
- **Protection of lock from the use of gunpowder;**
- **Protection of lock and bolts from effects of the introduction of gunpowder;**
- **Lock-case protection from explosives.**

Price patent claims:

"First to paint or coat the inside of the body and the inside lining or casing, and the iron sheets or plates forming the chamber of the lock-case of fire-proof safes, chests, and boxes, with a composition to prevent the oxidation or eating-away of the iron by the action of the salt or moisture contained in such chambers."

I was induced to adopt this remedy from having, on examining a safe made fire-proof on the steam generating principle, discovered that the iron plates and sheets enclosing the composition were considerably weakened by oxidation, produced by the chemical employed.

Another claim in the patent was for case-hardening the doors or lids and outer body of iron safes, chests, and boxes, or any part thereof, which gives to the surface of the iron plates the hardness of steel, and thereby renders them drill-proof.

The third claim was for inserting within locks used for iron safes, chests, and boxes, a series of compartments formed of strips of iron or other metal that were divided transversely, or of metal cast in the honey-combed form in those parts of such locks not occupied by the works, so as to prevent a sufficient quantity of gunpowder being placed therein for the purpose of blowing them open.

Another related claim was granted for the protection of the lock and boltwork from the effects of the introduction of gunpowder. The design described "for inserting in that part of iron safes, chests, and boxes, called the lock-chamber, wherein the large bolts are enclosed, a series of compartments or cellular work, so that were a hole to be drilled through the front plate of the door, there could not be inserted through the aperture, a quantity of gunpowder, which, if exploded, would be sufficient to force the lock-case inwards or the door outwards.

A patent obtained by William Milner, dated February 20, 1854, and

another dated December 20, 1854, though more particularly belonging to the chapter on powder-proof locks, may also be noticed here, as the latter comprises the filling of the large lock-chambers of iron safes with a solid substance, as " hard wooden packing." The former specification states:

"This invention is designed for the purpose of protecting locks, of whatever construction they may be, from the destructive effect of gunpowder, or other explosive compound or agent, and is more particularly intended to be applied to safes or such strong depositories as are required to be secured from the invasion of burglars or others."

"My improvement in locks consists in filling up all the open space or spaces usually left around the 'tumblers and other working parts of locks, leaving only sufficient space for the turning of the key, the slight lift of the tumblers, and the limited action of the springs, etc.; thus substituting for what has commonly been the 'box' of the lock almost a solid block of metal."

"This 'filling' may be effected either by casting or forming the lock solid with the exception only of exactly the open space required for the working or operative portions of the lock; or it may be made so as to be formed upon the 'cap' of the lock and fitted into the ordinary box of the lock, and thus also leave only the sufficient space required for working or opening and closing the lock."

"It will be evident, therefore, that the space which has ordinarily formed a receptacle for a large and destructive quantity of gunpowder being by my invention reduced to the smallest possible capacity, and the resistance also thus afforded to the effect of explosion will preserve the lock from destruction by any such means, and will necessarily cause the discharge of the violence through the keyhole."

It may be as well to remark here, that it is usual with burglars in operating upon a lock with gunpowder, to plug the keyhole, so as to cause the force of the explosion to "tell" against the lock or lock-case, and thus prevent "the discharge of the violence through the keyhole."

The other Price specification states:

"These improvements apply principally to that part of the door of

fire-proof or fire-resisting safes called the "lock case" that is, the chamber between the inner and outer door plates, in which the large bolts are usually placed and secured by the lock when shot or thrown into their corresponding recesses or bolt-holes in the top, bottom, and side of the safe.

The first part of my improvement is designed to extend the principle of preventing the destructive effect of gunpowder or other explosive compound or agent, in a similar manner as that secured to me by Letters Patent, dated the 20th day of February, 1854, as therein particularly applied to 'locks of safes.'

"The present improvement consists in filling up all the open space or spaces usually left between the inner and outer plates forming the door, with wood or other similar suitable material, leaving only sufficient space for the seat or position of the lock, and the working or passage of the bolts."

"It will therefore be evident that the great space forming the "lock-case" in doors of safes, etc., which has heretofore been a receptacle for a large and destructive quantity of gunpowder, is by this invention prevented from being available, as it is filled or reduced to the smallest practicable capacity."

"The second part of my improvements is a further reduction of the space or room for the action or presence of gunpowder, and applicable to the description of lock before-mentioned as the subject matter of the patent herein recited, and is effected by filling up nearly two-thirds of the space ordinarily left in locks for the passage of the key, and leaving only sufficient room to pass the key in, perform the operation of locking or unlocking, and withdrawing the key immediately after it has performed these operations, instead of turning the key around a complete revolution, as hitherto done, and by this improvement the available space for the presence or action of gunpowder is reduced to a minimum."

I am unable to discern any difference in principle between Milner's first and second patents and Walter H. Tucker's, dated October 1st, 1852, except, that in Milner's first patent "the space which has ordinarily formed a receptacle for a large and destructive quantity of gunpowder being by "his" invention reduced to the smallest possible capacity, is in his second "reduced to a minimum." The specifications of both these patents, together with Tucker's, will be fully described and illustrated by diagrams in the chapter on powder-proof locks.

CHAPTER FOUR: Requirements of an Iron Safe to make it Secure against Thieves and Fire

In deciding upon what means to employ to secure our valuables from thieves, we must not forget that as improvements take place in the arts and sciences, in the same proportion does the thief increase in ingenuity and intelligence. Therefore, even the improved safes and locks made have been found faulty and wanting, when operated upon by the present genre of skillful and scientific burglars.

An iron safe, to be secure against fire and thieves, must possess the following merits:

The iron plates forming the body should be of sufficient thickness and put together so that no violence or ingenuity could easily defeat them;

- **The door should be carefully fitted so that no instrument could be inserted between the edge and the outside of the safe. The iron of the door should be so hardened that no drill can penetrate it for drilling a hole to insert gunpowder into the lock mechanism. The lock-studs, by which the lock-case is secured to the interior surface of the door, should not be capable of observation from the outside or front of the container.**

- **The large lock, the bolts of which are thrown by a knob or handle, should be well made and of simple construction. This will negate the requirement that the case be taken off after it is once fastened to the back of the door. The large lock should be so contrived that in event of one or more holes being drilled through the door, there should be no space inside the chamber sufficiently large to contain enough gunpowder to blow it open. There should be bolts at the back and front in large safes. In those with double doors, there should be bolts all round.**

- **The case at the back of the door containing the lock and fire-proof composition should fit the interior of the safe as tightly as the opening and closing will allow. This is to keep out external heat, and prevent the escape of that moisture evolved by vaporizing material.**

- **The inside case that forms the chambers for the fire-resisting material should fit the inside of the outer body tightly and prevent the undue escape of the vapor in a fire. It should be so secured to the outer frame that no violence exerted upon the door should force the removal of such lining.**

- **The non-conducting and steam-generating composition placed in the chambers or within casings and at the back of the lock-chamber should be prevented from having any harmful effect upon the iron. When subjected to the action of fire, whilst the vapor would preserve the contents from combustion or damage of that kind, it should not injure plate or specie, or affect the writing upon, or substance of, papers or books. The thickness or quantity of the composition should be in proportion to the risk or probable duration of a fire.**

- **The small lock which secures the bolts should be one that would be easy to use, not liable to disarrangement, likely to wear well, gun-powder-proof, and above all, one that could not be picked. The key should be small enough to be carried without inconvenience.**

Although iron safes are not required or expected to be placed in a drawing room, they should be of such a design and so neatly finished as to please. They might be considered an ornament to the counting house.

Safes possessing all these qualities, and obtainable at a price within the reach of every shopkeeper is the goal that needs be achieved.

Mr. Granville Sharp, in his article on “Safes” in the work before referred to, says:

"It must, however, be observed, that the 'Safes' of the Great Exhibition (1851) *as a whole*, are distinguished rather by ornament and beautiful workmanship than by strength and practical

utility for banking purposes; they are too small, and they are too handsome, and, as a consequence, they are (proportioned to the accommodation afforded) far too costly."

CHAPTER FIVE: On the Iron Safes in General Use

Having in the previous chapters gone through the historical part of the subject, and having described all the improvements in iron safes for which patents have been granted, and having also stated what is required to make them really secure against both thieves and fire, I will next describe the various kinds in general use, explain their construction, and particularize those that afford the necessary security.

Cast-iron safes, the bodies of which are cast in one piece and the doors in another, are utterly worthless as preservers of their contents against fire or thieves. As a rule, no safe made of iron, without some other contrivance, can resist the effects of fire. Safes made of cast-iron, because of the brittleness of the material, readily yield to the blow of a hammer. They may be easily opened by the use of the drill, as well.

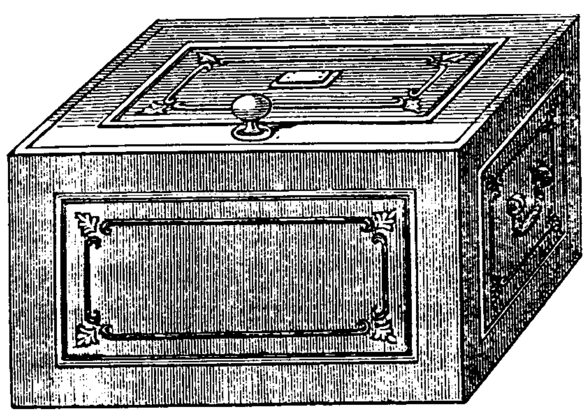

Figure 3. Cast-iron Safe

The locks for this class of safe are generally warded ones, which can be picked with a very simple instrument. As has been repeatedly proved, the large quantity of gunpowder that may be readily poured into the lock or lock-chamber through the monstrous keyhole can enable the burglar to blow it open at once.

They have seldom any bolts or fastenings at the back, and the doors or lids are hung with hinges.

To entrust valuables of any kind to the custody of such chests, is as bad as leaving gold watches and jewelry in a shop window at night without further protection than the wooden shutter. It is, indeed, offering a premium to the most ordinary thief or burglar.

Common wrought-iron safes with inside linings or casings left hollow are also valueless against fire. The linings in such safes not only take up the inside room, which is a disadvantage without an equivalent, but really deceives the purchaser, as he would reasonably suppose they contained some composition to give them the desired security. Many are made in this way, and as there is no external difference in appearance between these and those with filled chambers, the ignorant buy and sell them for fire-proof safes.

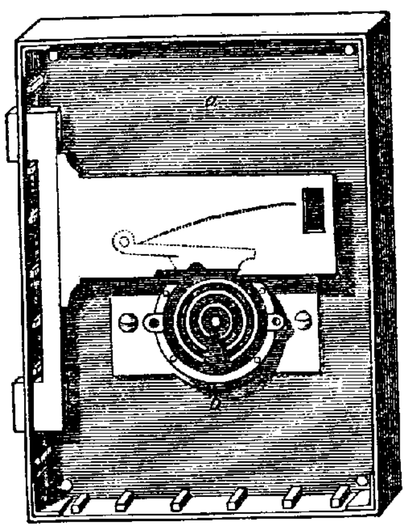

Figure 4. Lock-case with box of wards, as used for cast-iron safes and chests

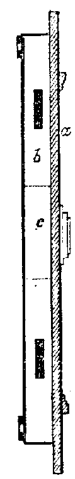

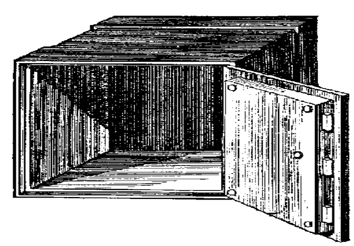

Figure 5. Section of door plat and lock-case-not fire-proof

Many safes are made of wrought-iron of great strength, having plates of 3/8"-5/8" thick. These containers do not have any inside linings at all, however, and are intended to be specially thief-proof.

If the doors of these are properly made, and

secured by an pick resistant and powder-proof lock, no serious objection can be brought against them, so long as they are not required to be also fire-proof.

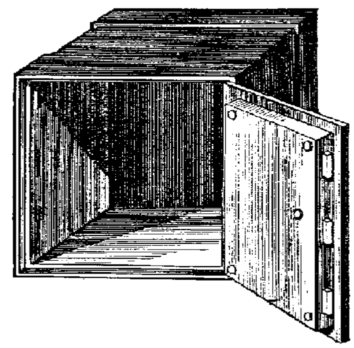

Figure 6. Strong wrough Safe, "hold-fast"pat

When a safe is constructed in such a manner that the case containing the look and bolts at the back of the door comprises only the plate that enclose them, the small lock is very liable to be forced from its place.

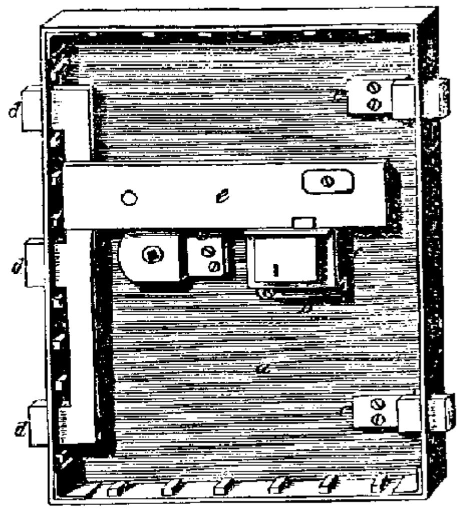

Figure 7. Lock-case as used for safes not fire-proof, and also for fire-proof safes where the door is not fire-proof-i.e., it has no composition at the back of the lock-chamber

Some years ago, one of Chubb's locks, fixed on a common iron safe, was forced open by the instrument before-mentioned a "jack-in-the-box." As this instrument is said to have the power of lifting three tons' weight, it is evident that some part of the door must give way under its pressure, and in doors made on the common principle, the lock and a portion of the lock-case must be torn away; then, by throwing back the bolts, the contents of the safe would be in the power of the burglars.

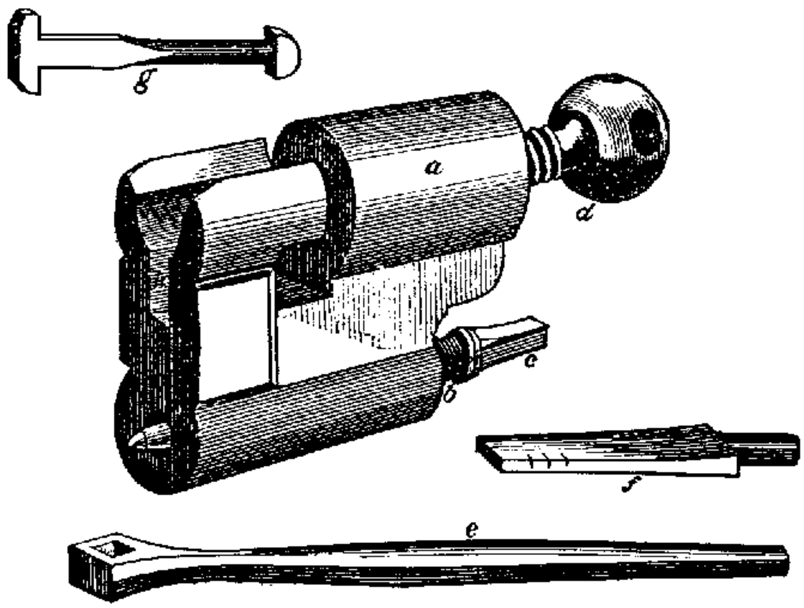

Figure 8. "Jack-in-the-box."

Since the occurrence of the before-mentioned accident, Mr. Chubb has adopted the plan, in his recent safe locks, of cutting a square piece out of the back of the keyhole and reaffixing it only by small screws, so that, on the application of the "jack-in-the-box," that single piece only would be removed.

Because the inside depth of the lock chamber is usually 1.5" and that of the lock, at most, only 1", it follows that if the latter, with this square piece at the back, must be let into the back plate of the lock chamber, (see figures 5 and 7) it would leave a space of ½"between the face of the small lock and the front door plate.

The result of this design, intended to prevent the safe from being compromised by the "jack-in-the-box," actually permits it to be opened by pouring gunpowder through the keyhole into the lock chamber and exploding it.

In fire-proof doors, the former contrivance would be useless, as such a result is prevented by the aid of another plate of iron enclosing the fire-resisting composition. (See figure 21.)

Wrought-iron safes made fire-proof by the use of a non-conductor only, are far less secure than those constructed upon the combined principle of non-conduction and steam generation. The

non-conducting power of asbestos, talc or mica, gypsum, plaster of Paris, cement, sand, and all the other materials which have been variously used, is, when subjected to intense heat, very soon overcome, and the contents of such safes are at once sacrificed. The heat having penetrated through the lining substance, finds the articles enclosed only too ready for combustion, and they are soon reduced to ashes.

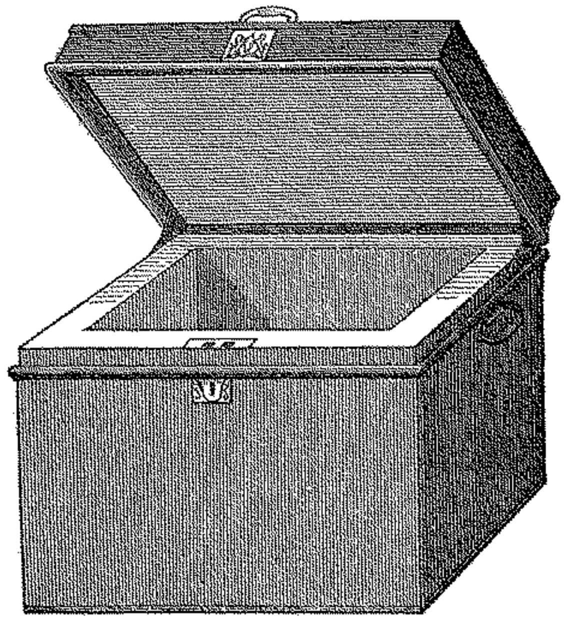

Figure 9. Sheet-iron Fire-proof Deed Chest

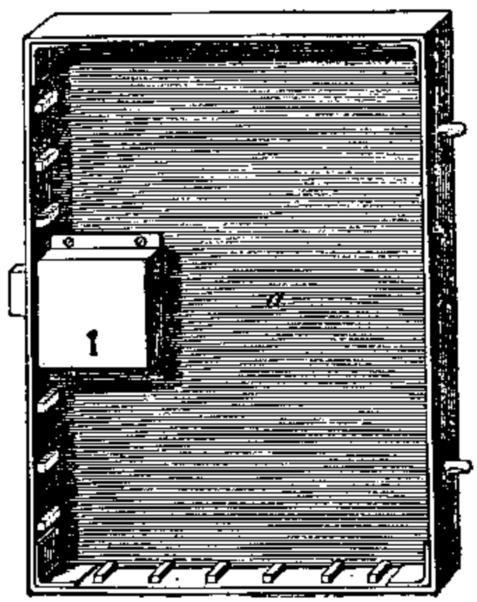
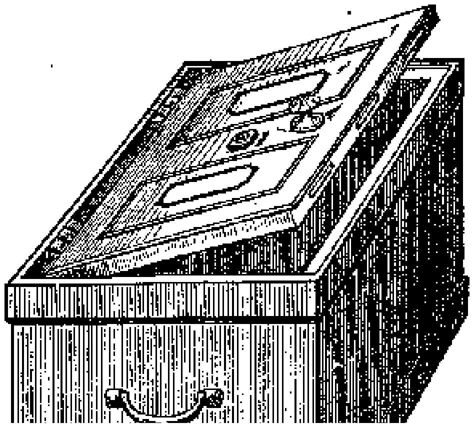
Deed chests made of sheet iron of the strength of 18 to 24 gauge, and filled with the steam-generating composition, however thick this may be, can never be secure either against fire or thieves. They are easily crushed or otherwise injured by the fall of building materials in a fire, and this not only allows the escape of the neutralizing vapor, but permits the destruction of their contents by the water used in extinguishing the fire; moreover, they cannot offer much resistance to violence. The large fires at Newcastle, Manchester, and other places, have sufficiently demonstrated that such chests and boxes are utterly worthless as fire-proof depositories, except for being placed inside stronger ones.

Another variety of safe, like the deed box, figure 9, is made of sheet-iron. These are manufactured in a similar manner to the ordinary japanned tinplate boxes, and the lining for the fire-proof composition is fastened to the outer body with solder.

As thief-proof receptacles for cash and plate, these safes are absolutely deceptive, and afford no better security than the cast-iron chests. Beside the insecurity arising from the thinness of the sheet-iron forming the body and door, the latter is secured by a lock with but one bolt; and the only security at the back, besides the hinges, consists in having two small studs projecting from the rim of the lock-chamber, which go into corresponding holes formed in the inner case.

These containers can be easily cut open with an iron bar or strong chisel, as well as by the drill, and one can be cut open with a steel chisel in a few minutes.





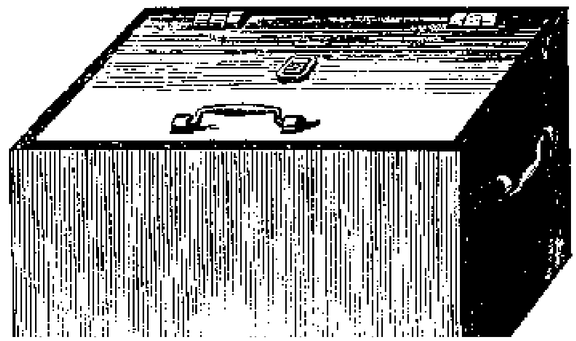


Figure 10. Lock and lock-chamber as used for sheet-iron Safes

Great numbers of chests or boxes for holding treasure are made of wrought iron of various strengths, of the patterns shown in figures 11-12, and are exported to several foreign countries, but principally to South America. Although these containers may prove secure against ordinary violence, they can readily be opened by means of the drill or gunpowder. The majority of those exported are of inferior quality, in consequence of the low price obtained for them. Consequently, they are but little better than the cast-iron safes. In many of them the lock-cases are made of cast-iron.

cast-iron.

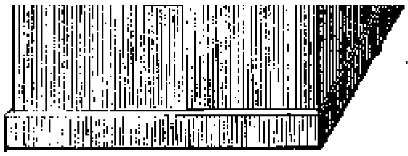

Figure 11. Money Chest, with outside bands

Figure 12. Plain Money Chest. The plates of body are riveted to angle-iron inside.

The door or lid is secured by two or three large bolts at the front, which are fastened on to the projecting bit of a 4" iron-door lock, and which, consequently are thrown by the key. This necessitates the latter being large and strong. The only security at the back is the hinges. The locks, also, in order to bring the chests at a lower price, although superior to the box of wards, are of an inferior character, and can be picked without much difficulty by those who understand their construction.

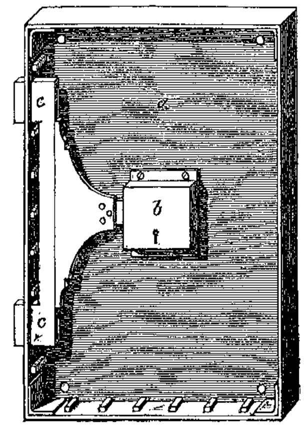

Figure 13. Lock-case as used money chests, containing a 4 the key of which throws

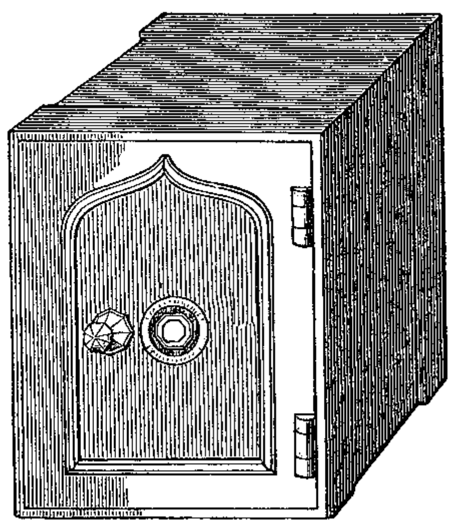

Figure 14. "Holdfast" pattern

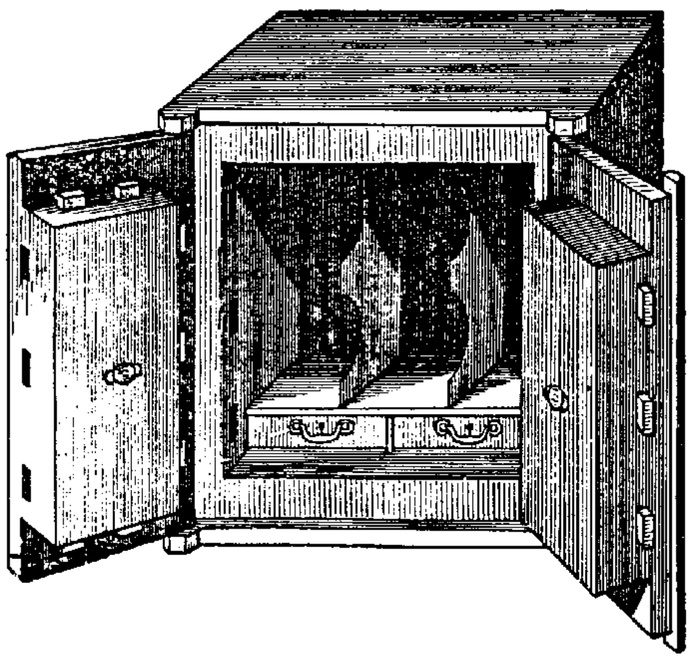
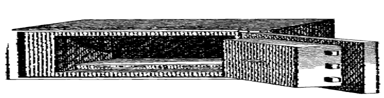
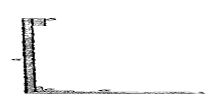
Safes made on this plan, with outside bands and massive hinges, are very generally, but erroneously, considered stronger than those made with inside strips and angle iron; but supposing the thickness of the plates the same in both cases, the outside bands on the former certainly lessen the security of the safe, unless

it be built in masonry and the door case-hardened, as they afford a purchase for clamps and drilling, tackle being applied to the front.

There is no advantage in making a safe in this manner, except, where such is not required to be fire-proof, it allows the interior of the safe to be quite square, (see Figure 5), there being no angle-iron riveted to the corners.







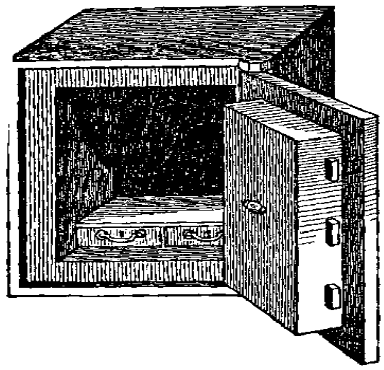


Figure 15. Double-door Safe, which was a welcome improvement

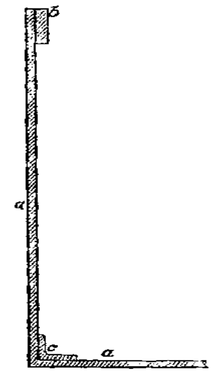

Safes with the plates both dove-tailed and riveted to angle-iron inside the doors that are hung upon centers are preferable. Besides offering no projections for attaching drilling tackle thereto, they are much neater in appearance, and the doors of the largest safes open and close without difficulty.

PRICE'S PATENT FIRST-CLASS FIRE RESISTING AND THIEF-PROOF SAFES.

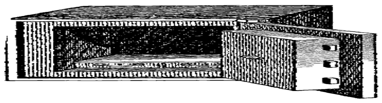

Figure 16. A safe with a single set of doors.

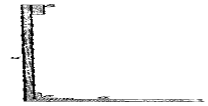

Figure 17. Section of body of a typical safe

These safes, which contain all the recent improvements, are made of the best boiler plates, the thickness of those forming the body being not less than a quarter of an inch, and are both dove-tailed and riveted to strong angle-iron inside. The entire configuration has been strengthened with bar iron and corner plates riveted to the inside of the front. For solidity, nothing can surpass this plan. Another technique is either to dove-tail the plates together, or rivet them to angle-iron alone.

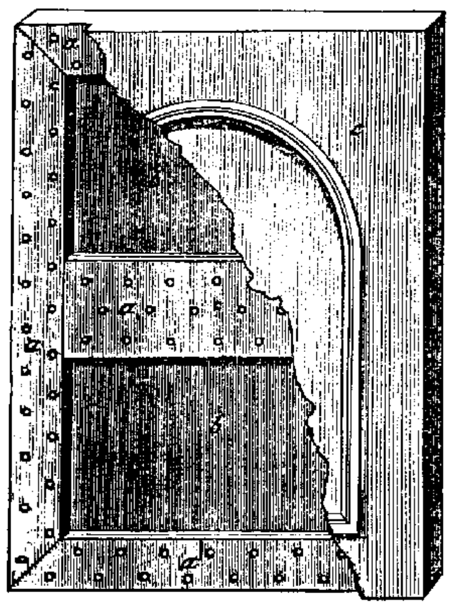

Figure 18. a a, The bar iron between the top and bottom plates. b b, The spaces or chambers filled with a non-conductor. c, The top plate

Either plan is sufficient for small or light safes, but should never be used singly in heavy or large ones. For the requisite security, both means must be employed. The doors are made of two plates, and paneled between with bar iron; thus making that part immediately over the small lock 1” thick of solid iron. (See figure 21a). The object in making the doors of two plates is for filling the hollow spaces (b b) with a non-conductor in order to make them somewhat fire-proof and to lessen their weight.

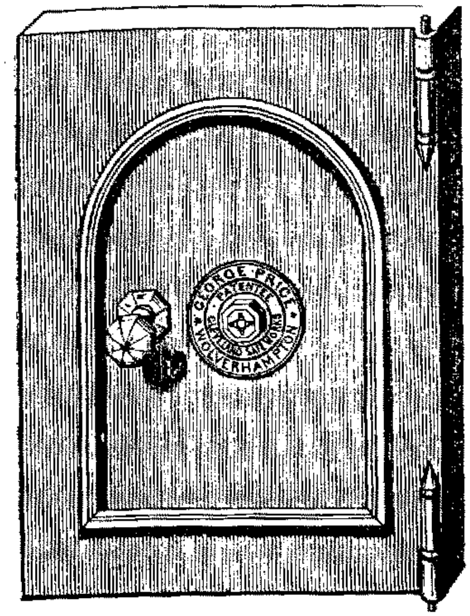

Figure 19. The same door complete

The cost of manufacturing such a door is much more than that made of one plate only, resulting from the extra amount of drilling, riveting, cutting, and filing of the former. The plates being each ¼″ thick, and the bars between ½″inch, make it, as stated before, 1″ thick of solid iron over the lock, and also for 2″ around the edge.

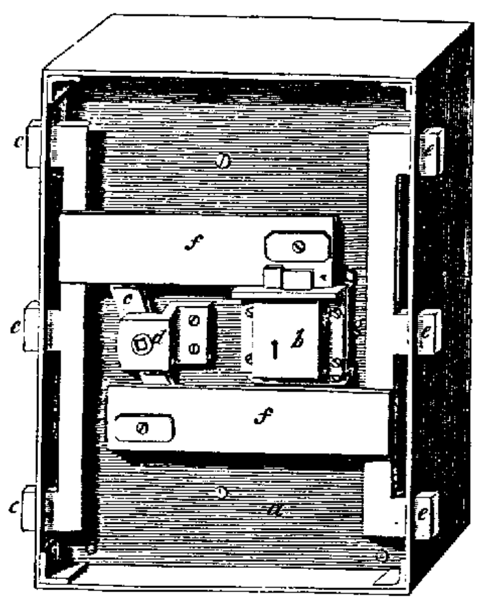

Figure 20. Modern lock-case, with small lock for fire-proof safes.

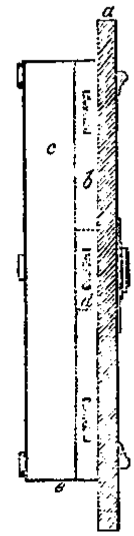
The modern safe-door locks now generally used are 3 ½" or 4" square, and the object of a mechanical and scientific thief is either to cut the lock out and remove it with a chisel, or by drilling or cutting away the bolt (see figures 20 and 21) which locks into the arm of the large bolts to open the door and thus get at the contents.

It follows, then, that the door is the vulnerable part of the safe and that the most vulnerable area is the square over the small lock. To provide against such a contingency, it has been customary in some special cases to screw a steel plate, the size of the small lock at the back of the door, or case-harden the plate of the lock itself.



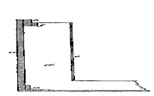


Figure 21. Modern lock small lock for fire-p

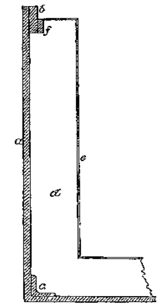
Unfortunately, as this only protects the small square over the lock, it merely obliges the operator to cut around it and take the lock and steel plate out together. In the alternative, the burglar must drill a hole under the small lock and fill the chamber containing it and the large bolts with gunpowder, and by exploding it, blow off the door.



The lock-chamber (see **Figures** 4,7,10,13,20a) will hold from five to thirty pounds weight of gunpowder, according to the size of the safe.

Another way is to screw a steel plate, the full size of the door, at the back of it, covering the whole of the small lock and the works of the large lock contained in the chamber; but this, besides considerably increasing the cost, adds little to the security, for, by drilling a hole in the door-plate, as previously described, the steel plate, from its brittleness, is easily broken with a punch, and the gunpowder is inserted as before in the lock-chamber.

In the process of manufacture, the body is first made, as before described, (see figure 17) by

riveting and dovetailing the plates together; the lining, (figure 22, e,) if a fire-proof safe, forming the chambers for the vaporizing material, is next made, and fastened to the inside with screws, and then the door is carefully fitted, and hung either with hinges or upon centers. However strong these may be, they add nothing to the real security of the safe, as many erroneously suppose, being used simply to hang the door with. The safety of the door depends altogether upon the

with bolts and back fastenings, the door would be just as secure, even were the hinges cut through or the centers knocked off.

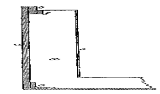


Figure 22. Se of fire-proof

A great improvement in the doors of safes consists in having two locks to secure them. In the old safes, the key (which, in consequence, must be very large, and the lock and keyhole in proportion) throws the bolts (see figure 4) at front, and there are sometimes iron dogs or studs at back; but more frequently there are none at all. In the modern safes, the bolts, from three to sixteen, according to the size of the door and the security required, constitute the large lock, and are thrown into the corresponding holes at the sides of the safe by a knob or handle, as shown in figure 20, and these are secured by the bolt of the small lock. This method I have proved by applying the force of several tons' weight upon the lock through the keyhole to endeavor to force the small bolt out of its place in the arm of the large bolts, but without accomplishing it to be perfectly safe and effectual, and it possesses the great advantage of requiring only a small lock with a small key.

Besides the convenience and comfort of a small key, as compared with the monstrous keys of the old safes, it considerably lessens the liability of the lock being destroyed or injured by burglars' instruments.

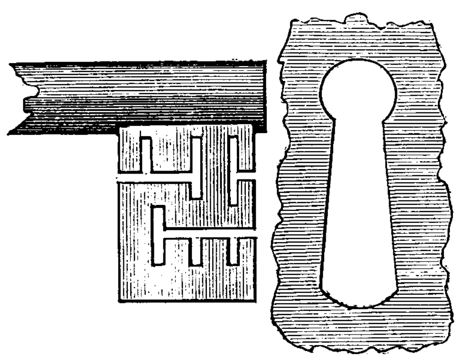

Figure 23. Key and keyhole of box of wards

There are two ways of securing the lock-case to the back of the door. In one method, studs or blocks are screwed into the door, (but should never go through it). If seen on the outside or front of the door, there is no security in this design. By punching these studs out, the door plate is opened, the lock unscrewed from its place, the bolts moved back, the lock-case lifted out,

and the contents exposed to view.

In doors of only ¼”or 3/8” thick, these studs must go through, and are generally riveted on the outside into a counter-sunk screw-hole. Figure 24 represents one of the studs, which, being screwed into the door, receives the lock-case upon it. In order to secure the lock-case in its position, small screws go through the corresponding holes in the rim, which are screwed tight into the studs.

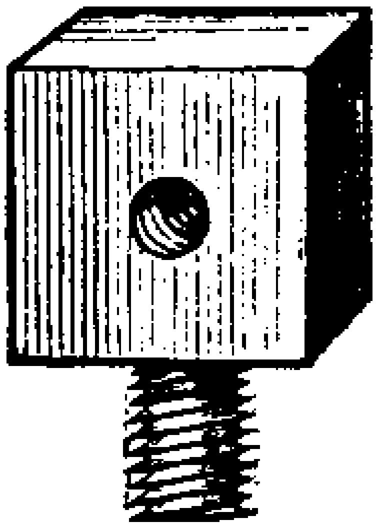

Figure 24. Flat lock-case stud

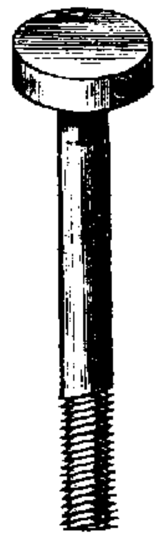

Figure 25. Cheese-headed screw. This was an early form of security fastening device

The heads of the small screws are then cut off and filed down level with the surface. This method gives a very neat appearance to the lock-case, and answers very well where the latter is not likely to require removing for any purpose.

As it sometimes occurs from various causes, the lock-case has to be taken off. In such a case, the studs or blocks (figure 26) to which cheese-headed screws (figure 25) firmly secure the lock-case to the door by going through the back plate are preferable.

The latter are easily removed without injury to any part of the lock-case by a key or spanner, made for the purpose; but in the other the lock-case is

disfigured by removing the paint to discover the screw-heads, which are more or less injured in getting them out.

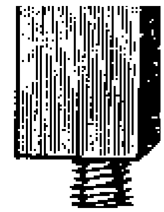

Figure 26. Square block

Figures **15-16** show the lock-cases secured by the latter means, and figures **6-9**, those with cheese-headed screws. The latter plan binds the whole fabric of the door together in a superior manner.

Figure 27. Key for cheese-headed screws

Frequent and extensive robberies have recently been effected by the two means before described, using drilling and gunpowder. One technique relies upon drilling or cutting a piece of the iron out of that part of the door covering the small lock, and taking it out. The other method requires drilling a hole through the door-plate into the lock-case, and then filling it with gunpowder and blowing it off the door.

These methods prove the insecurity of all safes, however well and strongly made in other respects, and shows the necessity of introducing such improvements as to make it next to impossible for the most persevering and accomplished thief to open one by those means.

To frustrate such a design, I have adopted the principle of case-hardening the exterior of the door or other parts of the safe, which gives to the iron plate the hardness of steel without its brittleness. The door is the most vulnerable part of the safe, and always a primary target of the thief. Thus, it must be evident that even were the operator provided with an unlimited number of steel drills and chisels, it would be no easy matter in the time permitted to thieves, to drill or cut through, by even combined manual power, a door of ½″, 5/8″, or 1″ thick.

The steel surface offers such a resistance to the drill as not only to receive no damage itself by the attempt, but the

operation takes off the cutting edge of such instrument, and renders further perseverance futile. The very fact of the door being case-hardened would doubtless of itself be sufficient to deter the most determined thief from attempting to open the safe by such a method.

Suppose, however, that a hole should be drilled through the door for the purpose of filling the lock chamber with gunpowder. In that case, from the cellular construction of the vacant parts of such chamber as shown in figure 28, it will be seen that it could only be forced into one or at most three cells, and that only to the level of the hole in the door.

If the gunpowder exploded, its power would be lost by the cellular filling giving way, from the circumstance of its being the weakest part. It would force neither the lock-case inwards nor the door outwards, and would therefore be quite inoperative.

The method of filling such vacant space with a solid substance is very inferior to this plan, as the power of only a few grains of gunpowder when exploded between two flat surfaces is well known.

The face of the small lock, by being supported in the lock-chamber upon a bridge of iron, (see figures 20-28) is brought in contact with the inside face of the door. This prevents gun-powder being poured through the keyhole into the lock-chamber, as may be done in most of the safes made until within the last two or three years.

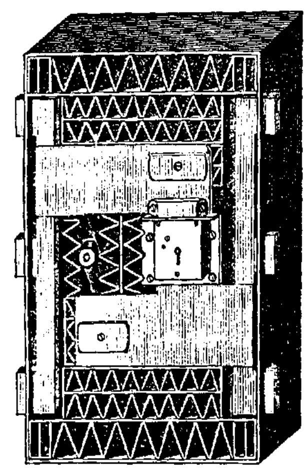

Figure 28. Price's pa gunpowder-proof lock-

In such safes the lock or box of wards is screwed to the back-plate of the lock-case, as shown in figure 13. This allows any quantity of gunpowder to be poured therein, **through the keyhole**, with facility by means of a small tube or bit of folded paper.

All **till** locks, unless specially ordered to the contrary, have a margin of 1/8”-1/4” which projects above the “cap” of the lock. Unless it is taken off, it allows an equal space between the back of the door plate and the face of the lock. This also permits gunpowder to be poured into the lock-chamber through the keyhole,

however small the latter may be.

From the insecure way in which hundreds of safes are constructed and are in daily use, protecting an enormous amount of convertible property, it is somewhat surprising that the public prints do not contain more accounts of robberies of these depositories effected by the most *ordinary* thieves, as hitherto, with few exceptions, such robberies have been the work of **scientific** thieves.

The absolute necessity for the doors of safes and strong rooms containing valuable property being made impervious to the drill is shown by the following account of one of the many robberies of iron safes recently effected in various parts of the Kingdom by that instrument:

"During the night of Friday, December 15th, 1854, the counting-house of Messrs. R. H. Greg and Co, at Quarry Bank, Wilmslow, Cheshire, was broken into, the iron safe opened by means of steel drills, and nearly £300 Sterling, in gold and silver, carried away."

"Both the Counting-house door and the outer door of the building were locked as usual, and the private watchman patrolled the yard, passing the front door at frequent intervals during the night, and yet, from all that we have heard, it appears probable that the thieves, who it is conjectured, were only two in number, must have been within the premises for five or six hours, and they appear to have got clear off with their booty."

"They had picked the lock of the outer door, and as soon as they had got within had shut and bolted it. Hence the private watchman, who tried this door several times during the night, always found it fast, the latest time at which he so tried it being three O'clock on Saturday morning, and it was found open by the box-keeper shortly after six O'clock, that morning."

"The Bollin flows near, and as that river was flooded and rising fast, there were men about at different times during the night looking after the paddles at the weir communicating with the works. Two of these men, in the employ of Messrs. Greg and Co., were sitting for a considerable time upon a rail close before one of the windows of the building within which during the whole of this time the robbers must have been at work, and yet they never made such a noise as at all to arouse suspicion."

"It appears that the thieves forced open the door of the counting-house at the head of the stairs, and that they then proceeded to work with the coolness and deliberation which shows that they knew well what they were about."

"The counting-house contains three windows; and as they could not 'operate' in the dark, the thieves had managed to provide and bring with them three curtains, one for each window, and a number of iron skewers to fasten up these curtains, so that no one from without would see any light, which, in the middle of the night would have doubtless excited suspicion at once and let to detection."

"The thieves appear to have carried with them to their 'work' everything they were likely to need, from the pick-lock for the outer door to the curtains and skewers for the windows, the steel drills for operating on the safe, and even to the oil for the drills!"

"When they gained access to the safe, which appears to have been the main if not the sole object of their labors, they seem to have made an exceedingly cautious scrutiny into its contents, one in which low cunning is strikingly blended with ignorance, amounting almost to stupidity."

"With a fear of detection not uncommon among raw 'cracksmen,' they looked at and handled a considerable parcel of bank notes, chiefly of five pounds each, and they quietly put them back again as dangerous articles to deal with. In 'collecting' the silver money, of which a considerable quantity was provided as necessary change for the wages on Saturday, they found in one drawer some base half-crowns. These they had handled and returned and their caution is not to be wondered at."

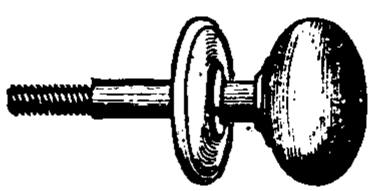

Figure 29. Knob to screw into the follow of the large lock.

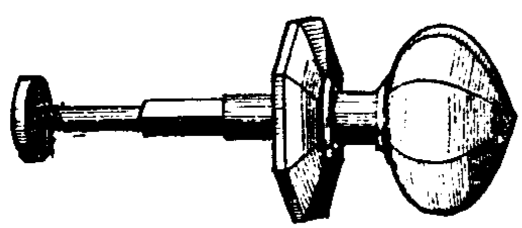

Figure 30. Octagon knob, with spindle to fasten into a nut at the back of the door.

Various kinds of knobs and handles for throwing the bolts and pulling open the door, and escutcheons for securing, the keyhole

from any foreign substance which might by accident get into the lock, and also from the prying curiosity of children and servants, are used. A knob of an octagon shape does very well for small doors; but large ones require a handle in the form of a 'T', which gives more purchase.

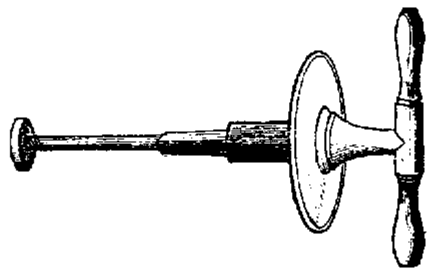

Figure 31. 'T' Handle for large safes and strong-room doors

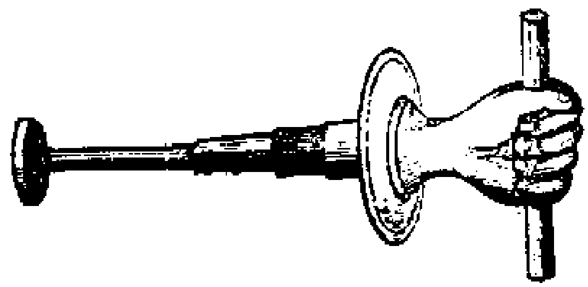

Figure 32. Fist handle, applicable for safes or strong room doors

One method of fastening these to the large lock is to screw them tightly into it; but it is very objectionable. The knob having to turn both ways, soon loosens and wears the screw. In turning, the bolts to fasten the door unscrews from the "follow," leaving the bolts unmoved. It is a neat plan; but that is all which can be said in its favor.

The best way is for a square spindle to go through the door, **"follow,"(444)** and lock-case, and to fasten at the back with a nut. By leaving a shoulder on the knob end of the spindle, the possibility of its being driven inside the safe, by breaking the knob off, is prevented.

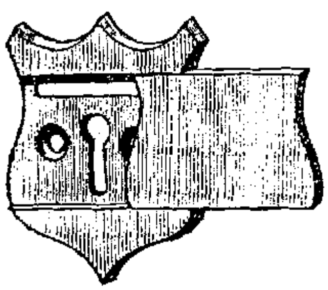

Figure 33. Slide Escutcheon-open

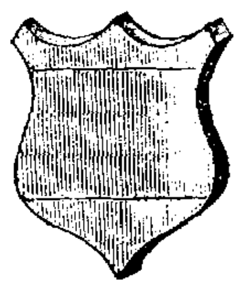

Figure 34. Slide Escutcheon-shut

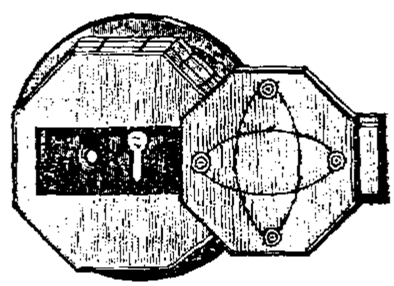

Figure 35. Secret Escutcheon-open

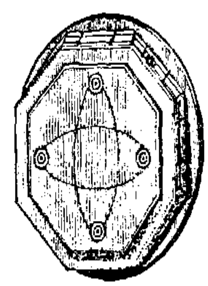

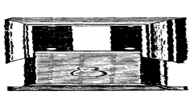

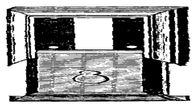

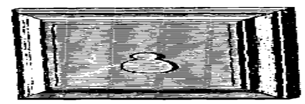

Figure 36. Se Escutcheon-s

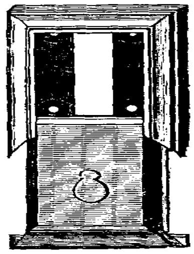

Figure 37. Lock Escutcheon-open

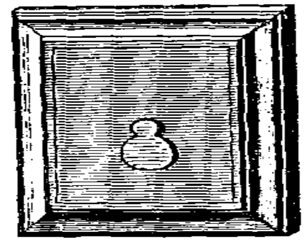

Figure 38. Lock Escutcheon-shut

The escutcheons most generally used on safes comprise the **"slide," "secret,"** and **"lock."** The "slide" is the most simple, convenient, and pleasant to use.

The "secret" has a spring that must be liberated by pressing on some particular spot with a pointed instrument such as a nail, or which is more frequently but improperly used, the key-bit, before it can be opened.

The lock escutcheon, though it does not give to the door any further protection against a burglar, is certainly useful in securing the keyhole from observation where many persons have access to the safe. It also preserves the lock from being tampered with by any person in the employ of its owner.

All these kinds are made of various designs, in the form of round or oval. Some are of the shield pattern, figure **34**, some octagon shape, as in figure **36**, and others square or oblong. For all escutcheon designs, one of the three principles is adopted.

In some escutcheons, similar to figures 37-38, the slide moves upwards; but this is very objectionable as after the key is inserted in the lock, the slide drops upon the pipe of the key and impedes it in the operation of locking and unlocking.

There is the same variation in the value of these escutcheons as there is in their design and construction; for one of an oval kind can be had for sixpence, whilst the lock escutcheons cost from twenty to thirty shillings each.

PRICE'S PATENT BANKERS' SAFES

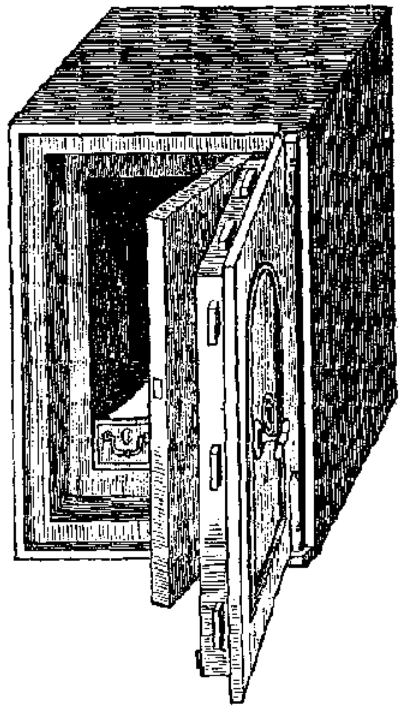

Figure 39. Bankers Safe with inner and outer fire-proof door

These safes are well adapted for the preservation of cash and other property of great value from burglars in detached buildings. They are utilized in locations where the burglar would have time, and could use noisy means by which to open the safe without fear of causing alarm.

An equal requirement would be for the preservation of books, bank notes, etc., from damage by fire, where the risk is unusually great, and the amount of combustibles contiguous to the safe would cause the fire to burn for many hours in succession.

The safe represented by figure 39 has an aggregate thickness of 6" of composition on every side, and would consequently preserve its contents in an intense fire from destruction for many hours.

The "bank locks" on many of these safes are said to be so constructed as to defy all attempts at **opening them(445)** by the most ingenious and accomplished pick-lock. Such locks were considered inviolable by both their inventors and owners until the year 1851.

The general knowledge acquired by most people of their construction, and which has resulted from the lock controversy

initiated by Mr. Hobbs picking Bramah's and Chubb's locks in that year has proven that very few made up to that period can be relied upon for their security.

This fact has so awakened the inventive and mechanical spirit of locksmiths and others, as to have produced improvements in these important articles, which not only combine all the essential properties of security against picklocks and gunpowder, but enable the manufacturers to offer them at a price which makes them available for every purpose for which iron safes or chests are necessary or required.

PRICE'S PATENT MERCHANTS' DOUBLE BOOK-SAFE

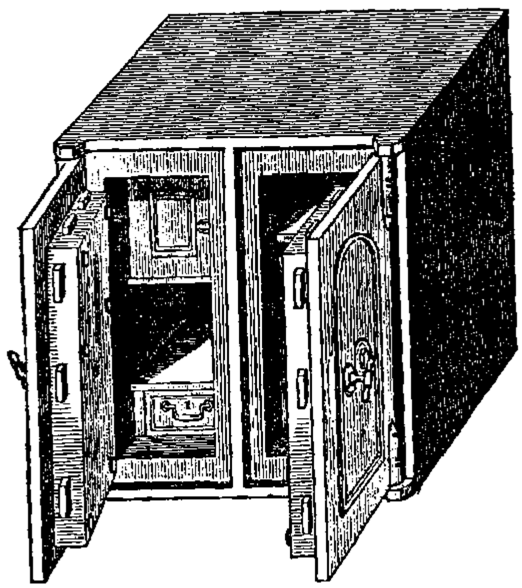

Figure 40. Merchants' double Book-Safe

This safe, which is the same as two distinct safes, is constructed precisely on the same principle as the others. It is particularly suited for a counting-house, and for establishments where the contents of one side would be required throughout the day by the various clerks employed, while the other side is intended for the use only of the principal. The locks are fitted so that the principal's key, as a master, will unlock both sides, whilst the clerk’s keys will unlock only their own. The cupboard on the principal's side is still more private and secure.

PRICE'S PATENT MODEL COUNTING-HOUSE SAFE

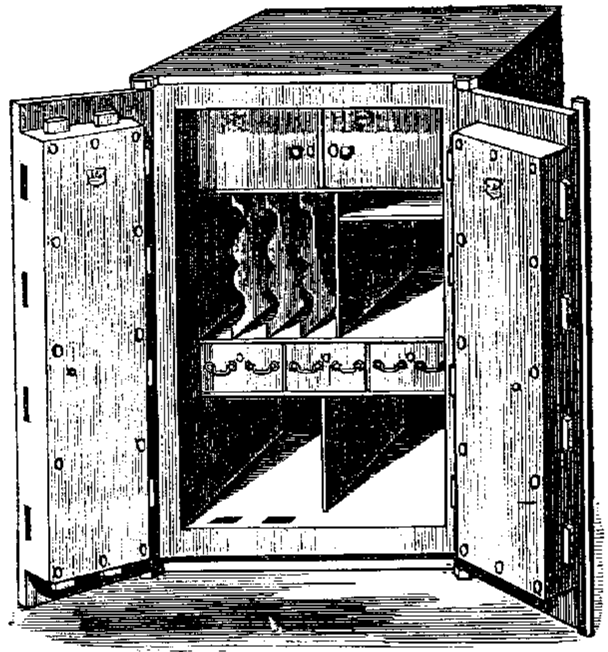

Figure 41. Model Counting-house Safe

This safe is constructed expressly for the counting-house or minor banking establishment, and is peculiarly adapted to preserve the contents both from fire and thieves. It contains all the improvements before-named. The lock of each drawer and cupboard is fitted with a different key, with a master key to pass all of them.

The left-hand door has four bolts at the side, with two each at the top and bottom; the right-hand door has four bolts at the right-hand side, and also four which shoot into corresponding holes or recesses in the rim of the lock-case of the left-hand door, with two each at the top and bottom.

The bolts of each door are moved with a 'T' handle, and secured by a 4" powder-proof unpickable lock of the best quality and construction, having two or more keys. It is thought by some that a safe with double doors, as shown in figure **15**, is less secure than one with a single door, as in figure 16.

By removing the astragal or iron strip, an instrument such as a saw-file could be inserted between the doors and the bolts cut through. This would thereby release the right-hand door. In these safes where such a space is left, and by giving the operator sufficient time, such a result might be obtained.

However, the labor and time required, are, in my opinion, a sufficient guarantee for their security in respect to such an operation. I have heard of several safes having been attempted to be opened in this manner, but in each case, the burglars were unsuccessful.

To effectively prevent such a contingency, it is only necessary to put bolts at the top and bottom of the right-hand door, identical to the left-hand one.

PRICE'S PATENT FIRE-RESISTING AND THIEF-PROOF PLATE CABINET AND CASH AND DEED SAFE.

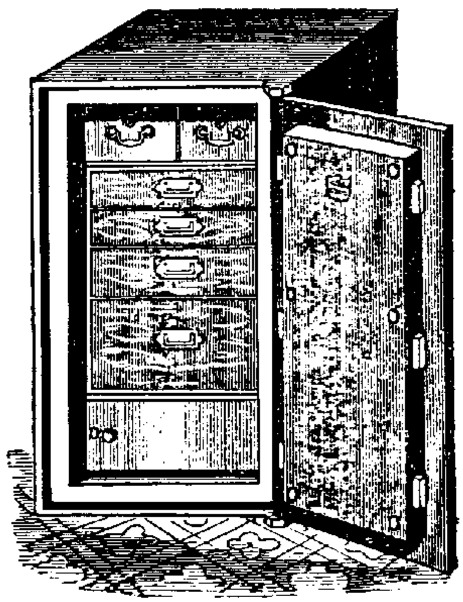

Figure 42. Plate Cabinet and Cash and Deed Safe

Figure 42 represents one of these useful depositories, which can be made of any required size and to any plan. This is constructed to hold any configuration of plates, silverware, and china.

The cabinet is made of oak with brass sunk handles. The iron safe enclosing it can be made of any desired strength to suit the risk, locality, and position it is intended to occupy. The two drawers, at the top are fitted in the safe, and are intended for cash, etc. The cupboard at the bottom is for deeds.

As wood is a bad conductor of heat, and as there is seldom a great amount of combustible material in any single room of a dwelling-house, the fire-proof composition in these chests need not be so thick as in the ordinary book safes.

It is customary with many to procure iron safes both for plate and books, and fit them up to their own taste and requirements with wood. This is an excellent method, as in a fire it would assist the chemical composition in preserving the contents from injury for a longer period.

PRICE'S PATENT FIRE-RESISTING DEED CHESTS.

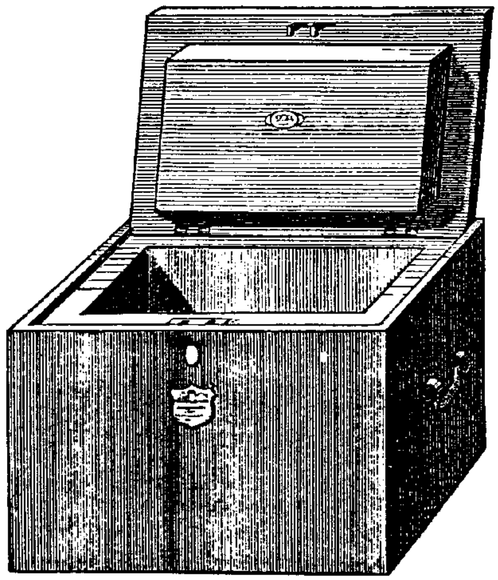

Figure 43. Fire-resisting Deed Chest for books and papers

These chests are constructed with special regard to the preservation of their contents against fire rather than against theft. Consequently, they are made of lighter iron than the safes; but although weaker, the plates of the smallest size are not less than 1/8″ thick.

They are strengthened with bar iron round the top, and are riveted to angle-iron inside, which enables the chests to stand a fall from upper stories without injury to the contents.

Deed chests made of **sheet iron** are utterly worthless, as they are so easily crushed, thereby exposing the contents. In many fires, the books and papers enclosed in such boxes have been more injured by the water used in putting out the fire, than by the fire itself.

A great fault with most of the safes and chests made in London is that the outer plates are much too light to resist violence of any kind. Hundreds of safes are hawked about the streets of the

City, the plates of which are only 1/16” thick. They are neatly painted and thus they are readily purchased by the brokers and sold at a rate accordingly. However low in price, they are the dearest that can be bought from the fact of their wanting those essential properties which make a safe secure.

CHAPTER SIX: Two Principles on which Safes are made Fireproof(446)

There are but two modes of making a safe fire resistant. The first is by using a simple non-conductor. The second is by using a combination of a non-conductor with a chemical, which, upon application of intense heat, generates steam.

Experience, and repeated experiments have proved that the use of the following substances, all simple non-conductors of various degrees, are capable of resisting fire for a very limited period of time: burned clay, powdered charcoal, dust, marble, porcelain, slightly burned clay, baked wood-ashes, fragments of earthenware, pottery, tiles, or bricks, sandstone, coarse sand, or gravel finely sifted, and fragments of slate. The combined principle of non-conduction and vaporization is the only plan by which bank-notes, books, papers, plate and specie, and other similar valuables can be preserved uninjured, when the receptacles containing them are subjected to the influence of fire.

Mr. Granville Sharp says: "The discoveries in chemistry have done much to promote security from fire. The sides of safes, when constructed with highly non-conducting chemical preparations, are capable of withstanding a great amount of heat for considerable periods." Now, Mr. Sharp's opinion of the value of such a plan is quite correct but he is quite wrong as to his estimate of the labor and expense of preparing such compounds. As it so happens, the best known and most effective chemical for such a purpose is one of the cheapest. That chemical is alum, a triple salt, being always either a sulfate of alumina and potash, or a sulfate of alumina and ammonia.

Professor Turner says: "It crystallizes readily in octahedrons, or in segments of the octahedron, and the crystals contain about fifty per cent of water of crystallization. On being exposed to

heat, they froth up remarkably and part with all the water forming anhydrous alum, the **alumen ustum(447)** of the Pharmacopaeia."

This, then, is the chemical I use. After grinding or crushing, it is mixed with sawdust. Sawdust is not only a non-conductor but an absorbant which is another important property for such purpose. Some makers use mahogany or other hardwood dust in preference to pine dust, as the latter is said to contain a large amount of resinous spirit.

It is said that the hardwood dust contains essential oil but it is also said that in some public tests of fire-proof safes, the paper contained therein were soiled (or singed) and the stain attributed to the "essential oil contained in the non-conductor." Both kinds may be used with equal advantage but pine dust is a better absorbant than mahogany, and I consider it the best as I attach great importance to its capability of absorbing more moisture than the other.

The linings, casings, or chambers which are made of sheet-iron, are well filled with this composition and firmly secured to the inside of the outer case by screws and not by solder, as solder melts at comparatively low temperatures. The back of the lock-chamber of the doors of safes and strong rooms is filled in the same manner. As soon as the outer case becomes sufficiently heated, the alum dissolves, and liberates its water of crystallization in the shape of steam or vapor. This is absorbed by the sawdust and thus becomes a wet fire-resisting and non-conducting medium. Surplus steam finds its way through the joints and angles of the linings or chambers, and saturates the contents of such safe, the whole being kept at the temperature of boiling water, 212°F. In such an atmosphere, books and papers will neither singe nor burn.

The capacity of the chambers and the quantity of alum and sawdust placed therein must always be in proportion to the probable intensity and duration of a fire. It is altogether a question of time for so long as the generation of steam can be kept up, so long the contents are safe. But the moment it is expended, and the interior of the depository exhausted of its protecting moisture, the fire then assumes its natural influence and the contents suffer accordingly. For this reason, where the risk is great, every assistance should be given to the safe by building it in a wall or otherwise surrounding it with masonry.

In private dwelling-houses, offices and counting-houses as well as premises where the amount of combustible materials is limited, an ordinary fire-proof safe, made upon the vaporizing principle, with two to three-inch chambers, is amply sufficient, and would be safe "for a much longer period than that during which a safe would be in direct contact with fire, in the successive conflagration of the parts of such building. In rooms forming part of or adjoining such warehouse as those in London, at Newcastle-upon-Tyne, Manchester, Glasgow, and Belfast, which are generally full of combustible stock, the safe should be of the most secure kind. It must be remembered that the space occupied by the fire-proof composition is always at the expense of the internal room.

The following extract from Messrs. T. Milner and Son's Pamphlet,(page 16), will explain their views on this subject: "Thomas Milner and Son having now had upwards of four years' experience of working their new patent, have equal satisfaction and confidence in laying their views before the public in reference to the important subject of the **preservation of documents(448)** from fire. After having submitted their manufactures to the most searching private and public investigations, in which they have had the kind assistance of scientific and practical men in the principal towns of the three kingdoms, they feel convinced that, within the various thicknesses of chambers tested at the London and Birmingham Station in April last, (say from one and a quarter to six inches in thickness), their depositories are equal to any degree of risk, and offer perfect security to valuable but uninsurable property, in all classes of buildings.

"The proprietors recommend their portable deed boxes, of not less than one foot inside measurement, such as tested from one to two hours in various towns for ordinary office buildings, dwelling houses, etc.; their double-chambered safes and boxes for warehouses and large buildings of ordinary risk."

The same, with an additional inner chamber, where the quantity of material or stock to burn is great, and the duration of fire likely to be increased; whilst, to the nobility and gentry, for their mansions, to bankers, merchants, and solicitors, where the risk may be still greater, they would recommend their double bankers' safe, as far exceeding in capability of resistance, any danger of degree or duration heat that might surround it in the conflagration of an extensive building. With 1000°F of heat (red heat) enveloping this safe for twenty-four hours, its contents

would not reach the temperatures of boiling water.

"The advantage of this principle over any other is the superiority of the non-conductor used, and the advantage that water or its vapor has, so shut up within the box or safe for use whenever wanted, over anything else in quenching or preventing fire. Iron, brick, or stone safes, however strong, will soon sympathize with the temperature of the surrounding fire; the barrier here used is that of nature herself, water, or the vapor under the control of chemical non-conductors, which cannot be made, excepting under artificial pressure, hotter than boiling water, and in this medium, papers will not burn."

It must be observed that in the second paragraph Messrs. Milner state, that although the exterior of the safe, when subject to red-hot 1000°F for twenty-four hours, would not cause the interior to arrive at "the temperature of boiling water". In the last paragraph, they state that the vapor thus generated by the external heat, 1000°F, acting on the chemical, "cannot be made, excepting under artificial pressure, hotter than boiling water".

Here is one of those contradictions and ambiguous explanations which abound in the pamphlet referred to. Why not have stated that the vapor or steam could not be generated except at red-heat, (1000°F) and that the temperature of this vapour under all circumstances, except when "under artificial pressure," (as in the steam-engine boiler) is neither cooler nor "hotter than boiling water," 212°F?

From various public tests which have been had by safe manufacturers, it appears that to make a safe resist the effects of red-heat for two hours and a half, the thickness of the alum and sawdust must be not less than three inches. To stand a fire for five hours, it requires a banker's safe, i.e., either one safe placed within another, thus making the composition from five to six inches in thickness, or else the chambers of the single safe must comprise the same thickness of composition. (See figure **39**)

The following account of an "extended demonstration of the security against fire," of Milner's patent fire-resisting safes, from the Edinburgh Courant, of October 23rd, 1855, fully confirms this opinion, and may be considered as a further explanation of the principle of steam-generation.

"We, the undersigned, have much pleasure in certifying that

we have this day attended the above public trials, during which Milners' No. 1 Safe and Double Banker's Safe have been submitted to a strong fire, and taken out in a red-hot state. The smaller one, in which was deposited a one hundred pound Bank of England note, and sundry documents, remained in the fire two hours and a half; and the Double Banker's Safe, containing a one hundred pound Bank of England note, and one pound note of the City of Glasgow Bank, several watches, plate jewelry, books, papers, etc., was kept five hours; and the contents of both, when taken out, were quite perfect."

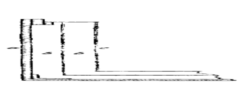
....."It still remains for us to notice the construction and Principle of fire-resisting safes which Messrs. Milner, after a succession of improvements and patents, have now brought to so great perfection. The safe, of whatever dimensions, is usually composed of a double chamber on all sides of about three inches in thickness.

The exterior is of boiler-plate iron; another iron plate separates the two chambers, and a third constitutes the interior lining. These chambers are filled with a chemical mixture, composed of soda, alum, potash, and other alkalis mingled in undissolved particles with mahogany or cedar dust.

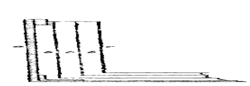
On the application of heat from without, these alkalis begin to dissolve, and the steam thus generated within the chambers finds its way into the interior of the safe, where it finally becomes condensed in the books and papers inside, keeping them in a moist condition. The hardwood dust, (of various kinds, carefully selected for their suitable chemical properties), though it does not assist in generating the steam, helps materially retain it, and prevent its too rapid escape, and too early expenditure.

The alkalis of the outer chamber are almost entirely dissolved and evaporated before the heat begins to operate upon the contents of the inner one, thus prolonging the security afforded in the event of the fire not being early extinguished. It is, of course, on the continuance of the supply of steam within, thus keeping the internal heat down to the temperature of boiling water, or 212°F, that the safety of the contents under prolonged exposure to fire depends.

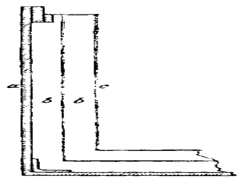
It is evident that the merely partial exposure of the safe to fire would incur a proportionately smaller expenditure of the resisting power, and that, however merged for the time in any conflagration, it would seldom, indeed, be surrounded by the



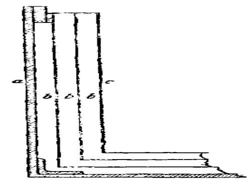
intensified and accumulated heat by which it was on this occasion tested. The fact, therefore, that the safes were taken from the furnace with little exterior injury, and with their contents, though necessarily somewhat soiled by the condensed steam from chemical mixtures in a perfect state of preservation, may be taken as a complete test of their capabilities.



In numerous great fires, particularly in the destructive conflagration a year ago, the safes of Messrs. Milner have been exposed to red-heat for many hours, and have brought out their valuable contents in safety. In all ordinary fires, therefore, it might almost be said in all possible cases, these safes afford ample guarantee for the preservation of their contents, their Phoenix-like capacity having hitherto successfully stood the most trying ordeal."



If, as the writer of this article states, the chambers of Messrs. Milners' safe are filled with "a chemical mixture, composed of soda, alum, potash, and other alkalis, mingled in undissolved particles with mahogany or cedar dust," such safes cannot resist fire for so long a period as those, the chambers of which are filled with alum and sawdust only.



As before stated, alum contains more water of crystallization than any other salt or alkali known, viz. fifty per cent. This water being the saving principle, it follows, that whatever the chemical may be that is used, and which contains less water of crystallization than alum, it cannot be so effective for the same period of time. "The quantity of this water varies much in different salts. Some salts take up very little or no water, other combine with more than their own weight, which is the case with alum, sub-carbonate of soda, and some others."

It will have been observed that in several specifications, double and triple chambers are named, and also in the various price lists of safe manufacturers, double chambers are also mentioned. Others have given this point much consideration, and have come to the conclusion, that such a contrivance does not add anything to the fire-resisting capability of a safe.

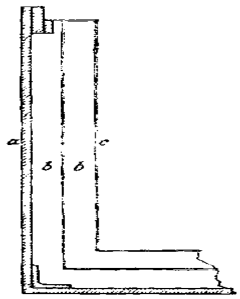


Figure 44. Section of fire proof safe, with double chambers

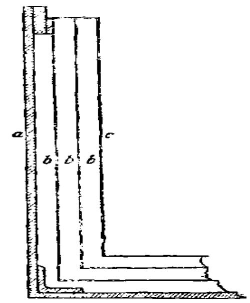

Figure 45. Section of fire proof safe With triple chambers

I cannot agree with the writer of the before-mentioned article in the Edinburgh Courant, that "the alkalis of the outer chamber are almost entirely dissolved and evaporated before the heat begins to operate upon the contents of the inner one". This is simply stating that if a kettle on a fire were divided in the middle so as to form two distinct cavities or chambers, the water would boil in the one, while in the other it would be only warm. The divisions forming the lining into separate chambers being made of iron, a good conductor of heat, can offer no resistance to the onward course of the heat.

Besides, the moment the steam is generated in the outer chamber, it finds its way through the other chambers into the interior of the safe, and by saturating the contents with moisture, preserves then from further injury. I can only account for its being adopted in the present day most, if not all, of the manufacturers, upon the supposition that as it was an early idea (being mentioned in Chubb's Specification, 1838), some advantage was supposed to be obtained by it.

Some safes with these double chambers have one filled with the fire-proof composition and the other left empty. This is decidedly wrong. The power of resistance consists in the thickness and quantity of the composition, and not in the number of compartments the space is divided into.

Messrs. Milner, in speaking of this non-conducting chemical compound say, "In long continued heat, the non-conductor discharges its pyrolignuous acid, which, combining with the alkali, forms a carbonaceous crust, pyrolignate of potass, the worst conductor of heat known; and from within this shelter the papers or books slowly give out again the large volume of steam that has been passed into and condensed in them, reacting most favorably in keeping down their own temperature, that of the box,

and the surrounding fire."

As pyrolignous acid can only be formed by the destructive distillation of the wood, consequently its production can only take place after the fire-resisting properties of the sawdust and alum are exhausted. I attach no importance whatever to Messrs. Milners' statement. I consider it too far fetched, as the essence of the principle is simply the steam or vapour, and I place no reliance upon the "carbonacceous crust" said to be formed. Indeed, the next step after its formation would be the destruction of the contents.

The vapour does not affect the writing or printing of books or bank-notes, neither does it injure their substance. Gold and silver may become somewhat tarnished, and would simply require cleaning. Even the delicate works of a watch receive no further damage than the liability of the steel parts to rust. This is obviated by being at once taken to pieces, and cleaned by a watchmaker.

The only substances which I have seen injuriously affected by the steam are the leather and forril bindings of books and parchment. The tenacity and cohesive properties of these materials, animal substances, appear to be destroyed. The former peel or drop off in bits, and latter all but disappear, while books bound in cloth, a vegetable production, remain unhurt.

In book-binding, leather and forril are applied with flour paste, and cloth with glue. The paper of ledgers and such like books is folded into sections, which are sewn with thread on parchment strips, and are fastened to the boards forming the cover. The result to these when enclosed in a safe, made fire-proof on the vaporizing principle and subjected to heat, is, that the steam annihilates the parchment strips, but leaves the paper and thread intact.

This is not to be wondered at, when it is known that for a long period, size has been made from parchment strips, simply by boiling them in water. It follows, then, that it is a physical impossibility to preserve a parchment deed from damage in an iron safe made fire-proof on the vaporizing principle, when such depository is subjected to intense heat, unless it be first placed in a steam-tight box. This astounding fact, first made known by me in the lecture I delivered in Scotland and Ireland in July last, I have proved by repeated experiments, and it has been fully confirmed by a great number of practical and scientific

individuals.

At a fire which occurred in January, 1849, in New Square, Lincoln's Inn, it was noticed, that whilst the parchment deeds were destroyed, or so much damaged as to be incapable of being read, (which accident settled more disputed titles than the Court of Chancery would do in half a century), the papers, although subjected to the same influence, were preserved.

The annexed lithograph shows the appearance of a parchment deed, after it was taken out of an iron safe made fire-proof on the vaporizing principle, which had been in a fire for two and a half hours. Before it was put in it measured 10 1/2" long, by 8 3/4" wide, when folded, comprised nine thicknesses, and was wrapped in a sheet of brown paper, and tied round with pink tape. The brown paper and pink tape are quite uninjured, as is also the piece of blue paper on which the stamp is impressed.

The deed itself, as will be noticed, is reduced to a cake of gelatin of the exact size of the drawing. Figure 47 is a piece, broken off the deed to show the fracture, and to expose to view the blue paper, which is in colour, appearance, and size, exactly the same as when first placed inside the safe.

For some time before this experiment was tried, my suspicion that these substances must be injured in some way was strengthened from having observed a safe which had been tested, and was exhibited in Mr. Milner's shop-window in Moorgate Street, London, containing books about an inch thick, being placed one above the other, and about half-way up the interior of the safe. All of which were stitched in paper covers, not one of them had a piece of leather or parchment about it.

Figure 46. Parchment Deed

Figure 47. Piece broken off to show the fracture and the stamp

The fact is, that leather and parchment constitute an irrefragable and positive test of the intensity of the fire surrounding a safe. For if the temperature of the interior attains that of boiling water (212°F) protecting medium of papers and books, plate and specie, the leather and parchment must inevitably suffer. Such a result is as certain and invariable as all the other laws of nature.

If such substances come out of a safe or chest uninjured, it simply proves that the temperature of the interior was below 212°, thereby showing that the fire had little power and intensity, and consequently was no test of the fire-resisting capability of the depository. When a book comes out of the fiery ordeal with its paper body perfect and its leather coat gone, it proves the test to have been a severe one, and consequently a fair one, and is the best testimony to the efficacy of the principle and the great value of the invention.

This important natural fact, if known by other safe manufacturers, has never been avowed. I cannot reconcile it with the various testimonials published, and numerously signed by the most respectable persons, the whole of which affirm that the parchments in the safes were severally tested in various parts of the kingdom, were preserved uninjured in some, that the wax seals "were not in the least injured".

Everybody must have noticed, in summer months, the sealing-wax placed in stationers' shop-windows, running at the temperature of summer heat, yet, in the chapter on testimonials are related several instances of the curious phenomenon of a fire-proof safe, the protecting medium of which to the contents is an atmosphere of 212°, of preserving this material from injury.

In all these tests one of two results must be admitted. If the temperature attained that of boiling water, (212°) the parchment and seals must have suffered beyond question. If they were uninjured, the temperature must have been below 100°, and consequently the tests were no tests at all. I must ask the reader's forbearance for having dwelt so much on this part of the subject. Its importance cannot be estimated to highly. It seriously concerns bankers and solicitors, and indeed all who enjoy possession of a parchment deed.

I shall conclude this chapter by copying from the Manchester Examiner and Times, a notice of a test of one of my safes made fire-proof on the vaporizing principle, which took place at Manchester, on the 12th October, 1854.

Milner's Patent, 1840, having then expired, and having been unsuccessful in making a safe fire resisting by the use of a simple non-conductor, I availed myself of the legitimate privilege of adopting his patent for the vaporizing material, and was anxious to test the quality of my safes by a public trial in that important commercial city.

Amongst the gentlemen who were present was an old inhabitant of the city, who bears a high character for integrity and honor. He stated, before the safe was placed in position, that he had been at several tests before, but that he did not consider them as such, and requested that he might be allowed to have the safe placed in the position he wished and elevated from the ground. I replied that I had not come there to act collusively. He was at perfect liberty to do as he pleased.

He then had the safe placed upon two rows of bricks, five courses high, and before locking the door, placed a piece of yellow blotting paper and a thin wood shaving in contact with the back-lining of the safe. He remained on the ground until within a quarter of an hour of the expiration of the allotted time for its remaining in the fire (two hours and a half) and until the last lot of fuel had been thrown on the fire, and returned in time to see the safe opened.

I may observe that having previously tried several safes made fire-proof on the same principle, both privately and publicly, I felt certain of the result. A safe of the same size, with the same amount of composition, and subjected to the same intensity of heat, for the same period of time, will always have the

contents affected in the same manner and in the same degree. To show my confidence in its capability, I placed my own watch on top of the books therein contained. The thickness of the composition in this safe was three inches.

"An experiment was made on Thursday last, with the view of testing the fire-resisting qualities of a book-safe, manufactured by Mr. George Price, of Wolverhampton. The trial took place in a yard near the Wesleyan Chapel, Lever Street. The safe was a 'No. 8,' being 28" high, 22" wide, and 22" deep. The chambers are filled with a steam-generating composition, the moisture from which, on the safe being heated, is forced within, in the form of vapour, a principle which has been found to answer by other makers. The door was fitted with one of "Tucker and Reeves" patent safeguard locks, the two inner drawers being secured by "Chubb's patent detector lock". Printed circulars were placed in the drawers, and six or seven volumes of books, chiefly 'Slater's Directories,' were arranged between the partitions above.

There were also loose papers, blotting paper, a wood shaving, and in addition to these, an account book, containing the signatures of parties present, who were witnesses to the various articles being inserted. Between the leaves of the account-book was inserted a five pound note. A gold watch was also wrapped up in paper, and placed inside. The door was then locked, and the key given to Mr. Councillor Warburton. The safe was raised in the center of the yard, upon two rows of bricks, (five courses,) so as to allow the fire to act underneath it. Shavings, wood, and coal were then thrown around it, the wood being arranged conically, so as to enclose the top of it, on which coal was also placed.

At a quarter to one O'clock the combustibles were lighted, and in a few minutes the safe was wholly enveloped in flame, which rose about two yards over the top, the heat compelling the spectators to retreat from its scorching influence. Mr. Alderman Heywood, Councillors Thackray, Thompson, Armitage, Worthington, and Howard, with agents of fire insurance offices, and other gentlemen taking an interest in the matter, were present.

The fire was kept up burning until a quarter-past three O'clock, two and a half hours from the commencement, and was then withdrawn. Being extremely hot, it required to be soused with water until four O'clock before it was sufficiently cooled to be opened. It appeared to unlock with little difficulty, although the door was slightly warped by the contracting influence of the

water. The brass handle seemed to have been partially melted, and broke on being pulled.

When the door was opened, the contents presented the following appearance: The vapour, supposed to be at a temperature of 212°F , had dissolved the glue on the backs of the volumes, and thus loosened the leather. The wood shaving was a little darker, the edges of a few of the circulars were slightly discolored, but most of them were untinged, and the books, with the exception of being dampened, presented no appearance of being near a fire; the papers in the drawers, opened half an hour later, were also safe. The watch was going, and indicated four O'clock; but on being taken out, the sudden transition from heat to cold seemed to paralyze its energies, for it held its hands over its face, as if for protection, and refused to move. The bank-note, with the book enclosing it were unsullied.

The five members of the city council named above, with a number of other gentlemen, placed their signatures to a document testifying their opinion of the fairness of the test, and stating the contents of the safe to have come out unscathed from the fiery ordeal. We may remark that so far as an artificial test can be made to resemble that of a building, the test was a fair one.

The conical mode in which the wood was made to surround the safe, threw the heat directly upon it, and from the length of time this was continued, the outer case must have been red-hot; indeed, the warping of the sides and door, and discoloration of the iron, were sufficient indication of this. We understand that Mr. Price rests his claim to a share of public support on two points. The fact is that he uses no solder, his object to it being, that it melts at a comparatively low temperature and then tends to allow the escape of what should be confined vapour. The second consideration is one of price, which will, no doubt, have its full weight with the public."

This faithful, intelligible, and scientific account of a most severe and honest trial, I insert in preference to anything I could say myself. The writer of it was a perfect stranger to me, and I do not now even know his name.

Mr. Granville Sharp says, at page 312 of the work before quoted, "There can be no uncertainty when a safe is made externally red-hot, (exposed to red-heat), and kept so for hours, with books and papers in it, which are afterwards brought out injured." "His

remark is very true, and when an iron safe is placed in an open space and elevated from the ground, and surrounded with fire on all sides, which is continually fed with combustibles so that the intensity of the heat is kept up for two or more hours in succession, and the contents, books and papers, bank notes and bills, plate and specie, are brought out uninjured, except that they are damped, such a trial is a scientific experiment of the greatest value, as it demonstrates beyond the possibility of doubt, that such property can be preserved in the hottest fire which should ever occur in any building.

I have frequently been asked whether fire-proof safes may be used with safety as magazines for gunpowder? To which I answer that those made upon the steam-generating principle will effectually protect it from ignition, when such safes are exposed to intense heat. From the moment the outer case becomes sufficiently heated, the water of crystallization is liberated from the chemical in the shape of steam, which at once enters the interior and saturates everything with moisture. The vapor is immediately condensed in and absorbed by the gunpowder, which thus becomes a wet mass, and will not explode until again dried.

Gunpowder should on no account be placed inside any safe or chest made fire-proof by the use of a non-conductor only. The two principles are diametrically opposite. On the vaporizing plan, everything in the safe, when subjected to fire, is kept damp until long after the chemical has parted with its water of crystallization. Whilst on the other plan, non-conduction only, the heat steadily progresses onwards, until it reaches the interior, and continues to prey upon the contents for a considerable time after the fire is withdrawn from the exterior.

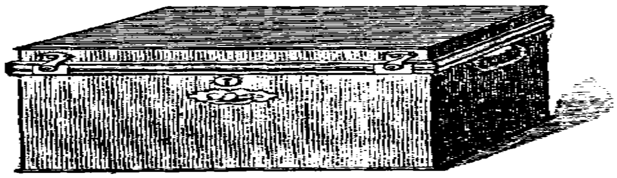
Although safes are advertised as being made fire-proof by the use of the "most perfect non-conductors of heat," there are no such substances known in science. There are various bad or imperfect conductors of heat, which retard its transmission in various degrees, but the best known non-conductor, asbestos, though an indestructible mineral, is a conductor of caloric.

CHAPTER SEVEN: On the Preservation of Parchment Deeds from Destruction by Steam and

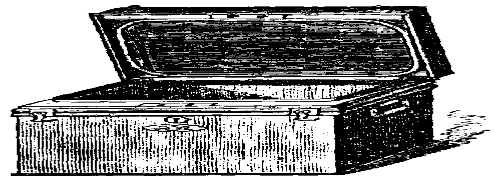
Damage by Water

The preservation of parchment from destruction by steam or damage by water has been partly anticipated in the previous chapter regarding the design of fire-proof safes, and the effect of temperatures above 212 °F.

When parchment is stored within an iron safe that has been made fire-proof on the principle of non-conduction only, such design will fail. When such depository is subjected to intense heat, the paper totally disappears, leaving nothing to indicate its previous existence but an ash almost too minute to be observed.



It follows that it is impossible to preserve parchment deeds and documents from damage in any iron-safe, upon whatever principle it may be constructed to resist fire, without some other contrivance when such depositories are subjected to intense heat. The discovery of the result, which is the simple effect of a cause, suggested the necessity of inventing a steam tight box for the express purpose of preserving parchments and other articles of value from the damaging or destructive effects of steam and water.



Figures 48-49 represent the box, which is made of planished tin-plate, and in the lid is an open tube which encloses a length of India-rubber cord. The latter, when the box is locked, presses upon a flange or sharp edge fixed to the inside of the top of the lower part of the box, and by hermetically closing it. This effectively makes it air, water, and steam tight.

As the air, oil heating, expands, and would thereby burst the box, a small valve is constructed inside the lock, which latter is placed outside of the India-rubber joint, and thus allows the air to escape through the keyhole without permitting the steam or water to pass into the interior.

In a small box, the act of locking imparts sufficient pressure for the desired purpose. Larger containers require the aid of several clips constructed on the wedge principle, and fastened to the lower part of the box. By drawing over the studs affixed to the lid, this effectively closes it and secures the interior from any injurious external atmospheric influence.

any injurious external atmospheric influence.

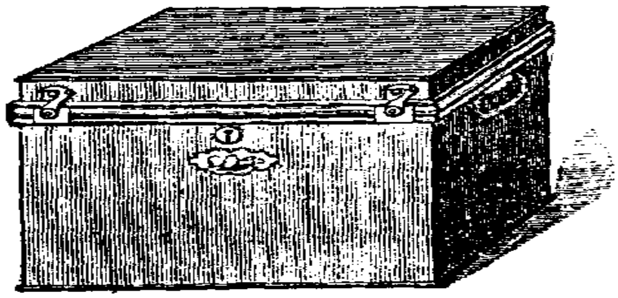


Figure 48. Patent Air, Water, and Steam-tight Box-shut

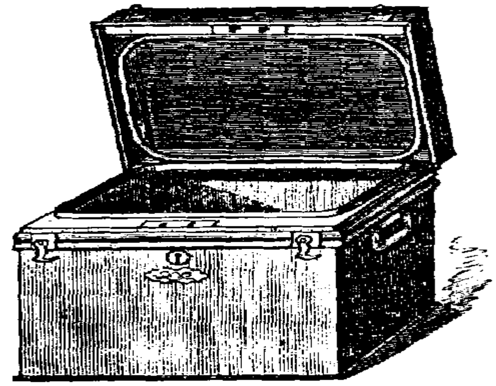

Figure 49. The same open

For bankers who keep "those books of a valuable character which have been filled," and other books and papers not in daily use in an underground closet or damp cellar, these boxes will be found invaluable. Such property must be kept dry, which is not easy in the case where they are confined for years underground. While Clifford's valuable invention for restoring books and papers may do much, it is better to plan to prevent the necessity for its use.

The importance of this branch of the subject cannot be better illustrated than by the debate which took place in the House of Lords on the Church Discipline Bill, on Monday, the 21st of April, in the present year 1856, when the imperfect and deplorable state of the registries in the numerous dioceses throughout England and Ireland was admitted by the various speakers on both sides of the question.

The cost of a central registry office in London for twenty-eight dioceses, to be made air tight, water tight, and fire-proof, was estimated in the bill at 100,000 Pounds Sterling. The importance of preserving these valuable records, however, is far beyond any considerations of pounds, shillings, and pence.

CHAPTER EIGHT: On Fireproof Closets and Strong rooms

Many of the remarks made in reference to iron safes, chests, and

boxes, equally apply to strong rooms and fire-proof closets with iron doors. Because the latter depositories are not moveable but are built with masonry, it may be well to state that these may be made additionally safe from fire by the use of the vaporizing material in the walls forming such closet.

Mr. Granville Sharp says, on this head, at page 312

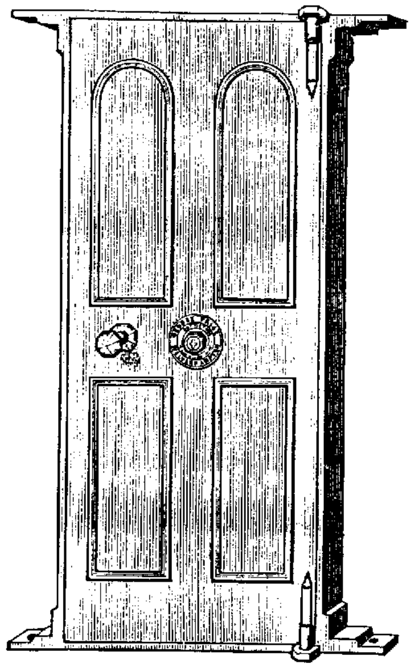
"Where the property to be secured is so valuable as in banks, it may be desirable to incur some slight inconvenience to place it in a locality which is in itself fire-proof. It is therefore suggested that bankers' safes, especially money safes, should always be *underground.* If this cannot be arranged, then they should have fire-proof floors above and under them, and be so placed that a passage should run round or about them and that no *wooden* fittings or furniture occupies the intermediate space. The safe wall should, of course, be constructed of stone and iron. The next wall to it might be built of hollow bricks, or these hollow bricks filled with some non-conducting material."

I quite agree with these remarks, except, that as underground places are always objectionable and inconvenient, I recommend, in preference, the closet to be on the ground-floor. It should be contiguous to the office or room of business, but built with a **double** wall of bricks or stone.

A space should be left between, of from four to six inches, to be filled with the alum and sawdust, with tubes built in the top of the wall, so as, in case of fire, to convey the steam generated by the heat acting on the chemical composition into the interior of the closet. Such a closet, with properly constructed fire-proof doors, would be quite as secure against fire as the case-hardened door is against thieves.

The doors of fire-proof closets and strong rooms are constructed in the same manner as the doors of safes, and are made either fire-proof to the contrary according to circumstances.

It may be well to remark here, that the majority of the iron doors now in use are most insecure from the circumstance of the locks which secure them being so very large, and the keyhole in proportion.



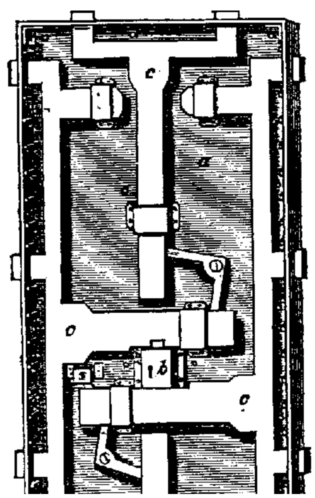


Figure 50. Iron Door and Frame for fire-proof Closet (Size, 6 feet by 2 feet 6 inches)

They can be made with sunk panels to imitate wooden doors, and to any style of architecture. The frame is made of bar-iron, 4″ x 5/8″, and the rabbet in which the holes or recesses are made to receive the bolts of the lock, 3″ x 1/2″. The frames are dovetailed together, and strengthened at each corner with strong plates.

This frame is sufficiently strong for any kind of door and

for any purpose. The width of the door is 28 1/2”, because the risk is very great. The large lock is constructed with four bolts at each side of the door, and two bolts each at the top and bottom. These are thrown with a ‘T” or fist-handle, (figures 31-32,) and secured by a four-inch lock, with a small key.

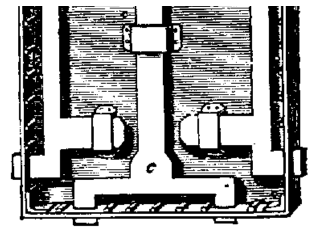

Figure 31. Large Lock for Iron Door, with twelve bolts. a, The lock chamber. b, The small lock. cccc, The large bolts

A plan prevails in Scotland of securing the doors of closets and strong rooms with a lock fastened to the back of the door, about 20” square, with a proportionate key. If this is the only security used, doors with this kind of lock could be opened without difficulty, either by gunpowder or the "jack-in-the-box," as well as by other burglars instruments. I heard one banker say that the lock and keyhole were so large that he could blow the lock off the door with a blunderbuss.

It is usual with some makers to use only a thin iron plate of from 3/16”-1/4” thick for the door, paneled around the edge with bar-iron. Where the closet is not required to be thief proof, this may do; but where security against burglars as well as fire is to be obtained, the plate should ½” thick throughout.

In constructing the large lock, in order to make the bolts move with ease and pleasantness, it is sometimes necessary to fix **anti-friction rollers** under the bolts. When there are bolts at both the top and bottom, as in figure 51, they are not required; the weight of the one assisting in moving backwards or forwards the other.

The strong room of the Wolverhampton and Staffordshire Banking Company, at Wolverhampton, is made of wrought-iron, about six feet cube, and is surrounded with masonry. The interior is fitted with iron shelves. It has both an inner and an outer door of strong wrought iron, which are cornered by a paneled wooden door of the ordinary description. The outer-iron door is secured by a compound lock, requiring three separate keys.

A very general method of securing the doors of closets, by bankers, in addition to the lock, is to have two staples riveted to the back of the door, through which an iron bar, after passing through the upper part of the frame of the door, descends through the staples and drops into another hole in the bottom of the

frame.

This bar is usually in the manager's chamber, which is over the room in which such closet is situated. For doors which do not possess in themselves the requisite security, it is a good contrivance.

Any contrivance, whether applied to safes or the doors of strong rooms, which necessitates more labor in the operation of opening them by other means, other than with their own keys, adds, in the same proportion, to the safety of such depositories against the attack of burglars.

Portable strong rooms are made altogether of wrought iron plates that are constructed in parts that can be fixed in any required place. They are usually made about six feet cube. Such a depository is an iron safe on a large scale.

A great additional security to banking establishments is obtained by using inside iron shutters. These can be made with sunken panels and moldings, and when painted and grained, look as well as those made of wood. The Commercial Bank of Scotland, in Edinburgh, is fitted with such shutters, which appear to be well made and constructed, and to answer the purpose very well.

CHAPTER NINE: The best place for a Fireproof Safe to Occupy

It is a matter of opinion as to the particular place that a safe should occupy within a structure. Some say that it is best to place it on the wooden floor, so that before any damage could happen to the contents, the safe would, by its own weight, be precipitated through the burning, and consequently weakened timbers, to the floor or cellar below.

This, doubtless, would preserve the contents from damage by fire; but unless the safe were sufficiently strong to bear the concussion and the effect of building materials falling upon it, the safe and its contents would be damaged by being crushed. No safes, however strong or well and accurately made, are water tight. The contents, if papers and books, but especially parchments, would be damaged or destroyed by the very agent

employed to extinguish the fire; the water.

Others recommend, as a good plan, the placing of the safe on a stone slab on the floor, or upon a slab let into a recess as a shelf. This would certainly preserve the bottom, but would necessarily retain the safe in its position to be affected more or less by the amount and intensity of the fire contiguous to it.

Another plan is to place the safe on a wooden stand, which is decidedly objectionable; as the less amount of combustible materials about it the better.

The best and most secure plan of all is to build the safe in the wall, or otherwise surround it with masonry. This technique insures that only the part subjected to the influence of the destructive element is the door. In several instances the contents of such safes have been found free from injury, although the **doors were not fire-proof**, i.e. they contained no non-conducting or vaporizing composition at the back of the lock-chamber. (See figure 5).

An instance of this kind occurred at Manchester, when "the counting-house and blowing-room" of Store Street Mill, in the occupation of Messrs. William Jones and Son, "were completely destroyed by fire," on the 15th of May, 1854.

The safe containing their "books, together with cash, notes, policies, etc.," had been built in the "chimney flue" and exposed to intense heat, yet to the astonishment of its owners, had preserved the contents.

Having seen a testimonial from Messrs. Jones and Son to Messrs. Chubb and Son, relating to the above circumstance, and observing the identical safe in the shop-window of the latter firm in Market Street, Manchester, my astonishment was great indeed, when I discovered that the door which had borne the whole force of the flame was not fire-proof, it had no fire-proof composition of any kind in it.

The other parts of the safe, from the paint being only discolored and not burnt, proved that but little heat had been in contact with them. This was so, as all the other surfaces, besides the door, were protected by the masonry forming "the chimney flue." This safe, then, preserved the contents, not from its fire-proof capability, but from the position it occupied in the "chimney flue."

When it is considered that at the great fire at Newcastle-upon-Tyne and Gateshead, in 1854, the contents of almost every fire-proof safe and box were destroyed, the choice of the situation in a building for the fire-proof safe to occupy should have the deepest consideration. It would be advisable to put up with any little inconvenience which should give additional security to the safe, whether against fire or thieves.

The purchase of a fire-proof safe should be looked upon as a kind of insurance, but with this difference: for the payment of *one* premium, although it maybe considerable, *a* perpetual policy is granted, there being no renewal except after the great value of the principle has been proved.

This principle of insurance, instead of being considered by the Fire Insurance Companies of its competing character, meets with their cordial support and recommendation. I once heard the manager of one of the largest fire offices in the Kingdom state that he wished Parliament would make a law which should compel every solicitor, merchant, and shopkeeper to entrust to the custody of a fire-proof safe the whole of their trade books and documents.

"While it is of paramount necessity that bank safes, whether for the deposit of money or of books, should be absolutely protected from the ravages of fire, it is almost as important that the possibility of their being flooded should be equally remote."

"Under the infliction of the extremely unpopular tax upon insurance, people usually feel that they have gone to the extent of their duty by the payment of this impost, together with the premium, leaving the provision of curative appliances to the fire offices."

"Some banks, however, have incurred the expense of fixing 'hydrants,' connected with the charged main, immediately outside their premises; at the same time keeping one or two lengths of hose pipe in constant readiness for immediate service, within five minutes of the discovery of fire."

"This arrangement is extremely valuable; but with regard to books and papers, next to the devastation caused by fire, must be placed the almost destructive influence of water, which, on such occasions, is supplied so copiously that a cellar or underground

safe is forthwith filled."

"To prevent this, it seems desirable that wherever deep drainage is accessible, a communication with the sewer should be provided, the safe door opening at some distance above the floor of the vault. When such an exit cannot be obtained, perhaps it would be desirable that a well or cesspool should be dug, and if necessary a powerful external pump connected with it, by which the water poured upon the building might be drawn off at a convenient distance."

"The pump should be of such character as not to become injured by remaining long unused; otherwise, any defect which might arise from this cause, or from want of care, would probably be discovered only at the moment when everything depended upon its being found in perfect working order."

Such a plan may be carried out by bankers, whose requirements are of an extensive character, and whose means are ample to effect such an arrangement. However, what are the thousands of private gentlemen, merchants, manufacturers, and shopkeepers, to do, the aggregate of whose property in deeds, books, bank notes, bills, and other perishable articles, amounts to so many millions?

There is only one answer. After possessing themselves of a proper safe, and assisting it to preserve such property by every possible means from destruction by fire or abstraction by thieves, they must provide themselves with such a receptacle for placing inside their safe as will effectively preserve such perishable contents from destruction by steam or damage by water. The only invention that has yet been introduced for this purpose is Price's patent air, water, and steam-tight box, as described in Chapter 7.

CHAPTER TEN: On Powder-Proof Locks

Price Gunpowder-proof lock
Tucker and Reeves "Holdfast" lock
Chubb Detector Lock, powder-proof

Since the thieves and burglars have been operating upon the doors of iron-safes by filling the locks or lock-chambers through the keyhole with gunpowder and thereby blowing them open, several modes have been patented and adopted for preventing such depositories being opened by such means.

The original invention of this kind is that of Walter H. Tucker, whose specimen lock was exhibited in the Great Exhibition of 1851, and was patented October 12th, 1852. The security part of this, and all the other principal locks, will be treated in the chapters on the old and modern locks. Mr. Tucker, in his specification, stated:

"My invention consists in so making the frame of the lock that it may be cast when made of metal, or made of wood so as materially to diminish the cost of production without lessening the security or durability of the lock; and this effect by making the frame so generally solid that it may be cast complete, or made of wood."

"I may state, in addition, that the lock is, as a whole, so constructed as to be perfectly secure against attempts to open it by gunpowder or gun-cotton, there being no opening large enough to admit either in such a quantity as to cause damage."

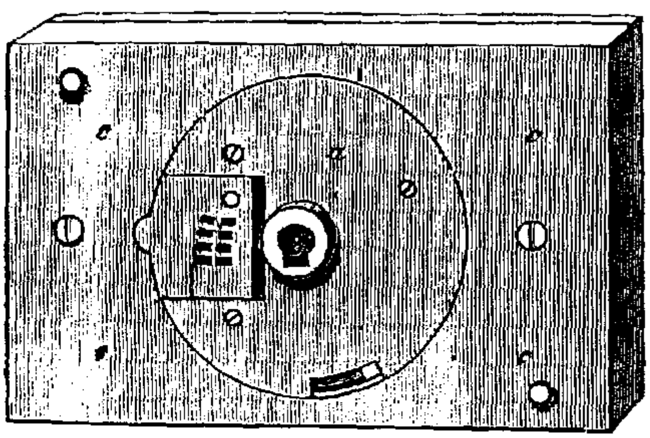

Figure 52. Tucker's gunpowder-proof closed keyhole lock, with the top plate off. 'a' The works of the lock. 'b' the keyhole. 'cccc', the other part of the lock cast solid.

From the above figure, it will be apparent that very little gunpowder could be inserted into this lock, even if it were placed in a horizontal position.

The next patent is Milner's, dated Aril 21st, 1854, and although described earlier, I think it will conduce to a better understanding of the subject to repeat it here.

"This invention is designed for the purpose of protecting locks, of whatever construction they may be, from the destructive effect of gunpowder or other explosive compound or agent, and is more particularly intended to be applied to safes or such strong depositories as are required to be secured from the invasion of burglars or others."

"My improvement in locks consists in filling up all the open space or spaces usually left around the 'tumblers and other working parts of locks, leaving only sufficient space for the turning of the key, the slight lift of the tumblers, and the limited action of the springs; thus substituting for what has commonly been the 'box' of the lock almost a solid block of metal. This 'filling' may be effected either by casting or forming the lock solid with the exception only of exactly the open space required for the working or operative portions of the lock, or it may be made so as to be formed upon the 'cap' of the lock and fitted into the ordinary box of the lock, and thus also leave only the sufficient space acquired for working or opening and closing the lock."

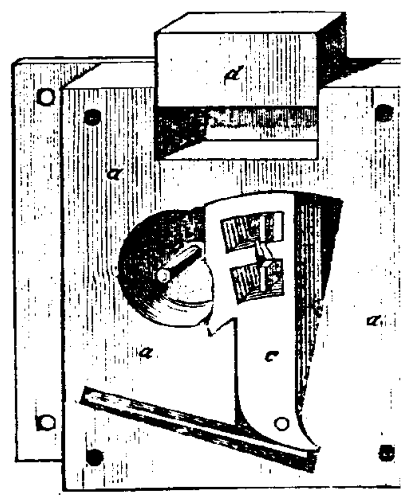

Figure 53. Milner's Patent the "box" solid applied t Protector Lock. aaa, The solid. b, The space required in locking and unlocking. tumbler. d, The bol

"It will be evident, therefore, that the space which has ordinarily formed a receptacle for a large and destructive quantity of gunpowder being, by my invention reduced to the smallest possible capacity and the resistance thus afforded to the effect of explosion, will preserve the lock from destruction by any such means, and will necessarily cause the discharge of the violence through the keyhole."

As stated before, I am unable to discover any difference in principle or construction between this lock of Milner's and that of Tucker's. (See and compare figures 52-53.)

After Mr. Milner had obtained this patent, he got up a trial to test its **powder-proof(449)** capability, which is described as follows in a Liverpool paper of that period:

"Messrs. Milner and Son having applied a new patent powder-proof lock to their safes, recently submitted the contrivance to the test of a trial at the Phoenix Works, Liverpool, in the presence of William Brown, Esq., M.P., several members of the Watch committee, Major Greig, Head Constable of the Borough, and various other gentlemen."

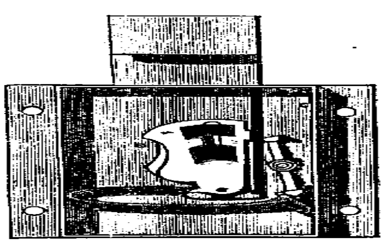
"Mr. Milner, after alluding to the frequency with which safes of different constructions had been of late forcibly opened by the introduction of gunpowder into the lock by means of the keyhole; and having explained that the destructive agent might be introduced in still greater quantity into the chamber which contained the lock by the process of drilling a hole through the front plate of the door, proceeded to exhibit one of the old locks, and also one of the new ones."

"The former consisted of an iron box into which the various wards and levers, popularly known as the 'works', are fastened. The remaining portions of the lock were completely void and capable of containing a considerable quantity of any explosive matter that might be forced into it."

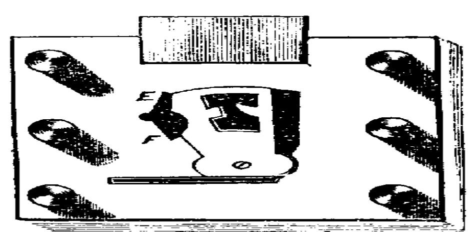
"He explained that into a lock suited to the medium size of a safe, constructed on the old or ordinary principle, about half-a-pound weight of gunpowder might be introduced, while larger locks would of course contain a greater quantity."

"He next showed one of equal power, but of smaller dimensions, in which every morsel of space not occupied by the 'works,' or essential to the working of the parts, was filled up solidly with metal, thus reducing the vacuum in its interior to the smallest possible amount."

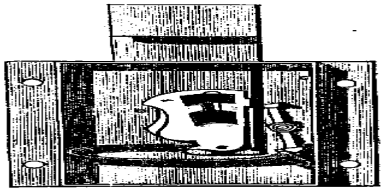
"Both of these are what are known as the patented six-lever locks. By the improvements thus effected, the lock did not afford space for more than half a thimbleful of powder. To obviate still further the possibility of applying gunpowder in any way to the opening of the safe, Mr. Milner showed that the chamber in which



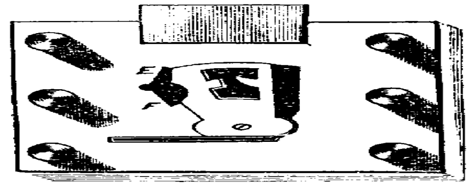
the lock was placed was completely filled with soft spongy timber, which, in the event of being penetrated with a drill, would of itself half fill up."



"This would leave the aperture for the reception of any material whatever, exceedingly small. As a still further protection, however, he showed that this timber was protected by a plate of hardened steel, which would resist almost any attempt at boring from the outside."



"One of the locks being packed as full of powder as possible, and an explosion produced by means of a fuse, the screws which bolted the outer to the inner door were then unfastened and it was found that the lock had not sustained the slightest injury. All the levers and moveable portions were still in good working order, the only impediment being the dirt caused by the burnt powder."



"An experiment was next tried with a lock of the old description, into which about one half pound of gunpowder was introduced. The explosion caused the door of the safe to be driven to a distance of several yards; the lock completely destroyed, and every means of barring access to the interior entirely removed."

The next patent connected with this subject is Milner's second, dated December 20th 1854; but I cannot discover any difference in principle, and, very little in construction between this and his first patent, with one exception. In the first patent "the space which has ordinarily formed a receptacle for a large and destructive quantity of gunpowder being, by this invention "reduced to the smallest possible capacity." is in the second "reduced to a minimum." The following figures, with the explanation illustrating the last patent, are taken from his published list of prices:

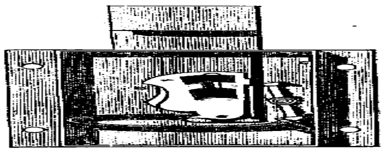


Figure 54. Usual open Detector Six-lever Lock. "Open lock, capable of holding from eight to forty-eight ounces of gunpowder, such as generally used for safes. All locks, excepting Milner's solid lock, (fig.55) are open to the same objection, more or less, and may be easily blown open."

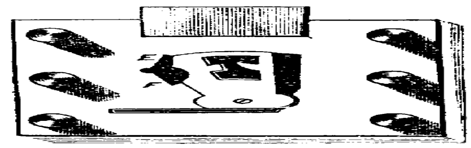

Fig.55. Milner's Patent Solid Powder-p
"Milner's (double) patent solid gunpow
lock. Keyhole and turning space for ke
hold as much powder as may be exploded
times without effect. Put in the key,
at 'F', turn to the right, and take out
To unlock, put in at 'E' and take out a

Mr. Milner states that figure 54 will hold from eight to forty-eight ounces of gunpowder, and he must certainly means this to apply to the locks on the 40,000 safes he had previously manufactured. I have examined many six-lever locks as shown in figure 54, but I cannot get any of them to hold even his minimum quantity. The following table shows the exact quantities each lock will hold, both in a vertical and in a horizontal position.

Description	Vertical	Horizontal
Common Six-lever Lock- 3"	47 grains.	9 gr. 8 gr.
Common Six-lever Lock- 3 1/2"	5 gr. 8 gr.	1 1/2 oz.
Common Six-lever Lock- 4"	12 gr. 6 gr.	2 oz. 5 gr.
Tucker and Reeves' Holdfast- 3"	5 gr.	20 gr.
Tucker and Reeves' Holdfast- 3 1/2"	6 gr.	23 gr.
Tucker and Reeves' Holdfast- 4"	12 gr.	35 gr.
Cotterill's Climax Detector- 3 1/2"	9 gr.	26 gr.
Cotterill's Climax Detector- 4"	9 gr.	26 gr.
Gibbons's Detent, and Price's Gunpowder-proof- 3"	20 gr.	1 gr. 24 gr.
Gibbons's Detent, and Price's Gunpowder-proof- 3 1/2"	20 gr.	1 gr. 24 gr
Gibbons's Detent, and Price's Gunpowder-proof- 4"	25 gr.	2 gr. 13 gr.

It will be noticed that it was an "old lock" that was experimented upon at Liverpool, and which Mr. Milner stated would hold eight ounces of powder. However, **figure 54** represents it as a six-lever lock, which he states will hold from eight to forty-eight ounces! Verily, how is it possible to reconcile such statements. I presume what he meant by an "old lock," is the box of wards, as shown in **figure 4**, and which has a keyhole the size of the one shown in **figure 23.**

To fill such a lock with gunpowder and then blow it open and call it a six-lever lock, is a deliberate and an absolute misstatement.

The locks as previously stated now generally used by safe-makers, are only 3 ½"-4" square. In drawing a comparison between these and Milner's "gunpowder-proof solid lock, I ask is it correct or fair to state that the former "will hold from eight to forty-eight ounces of gun-powder?"

At another test of this lock which took place at Newcastle-upon-Tyne, in December, 1854, during the second explosion, the door-plate parted from the lock and lock-chamber, and was thereby opened. The following account of this trial is taken from the Newcastle Chronicle, of December 22nd, 1854.

"A trial of Milner's New Patent Powder-proof Solid Lock and Safe Door, took place in the Corporation Yard, on Wednesday, in the presence of the Mayor, and about one hundred gentlemen."

"The lock-chamber was taken off and the lock examined, and the chamber replaced. The safe was carefully closed, and the experiment commenced by Mr. Dunne, chief superintendent of police, placing about half ounce of powder in the keyhole, which was plugged, leaving only a small space for the insertion of the match."

"The explosion took place without apparently damaging the safe in any way, but it was found that it had enlarged the cavity of the lock so much that it would now contain about one and one half ounces of powder."

"On a second explosion, the sheet iron front of the door was forced open two or three inches, but the lock still seemed to hold fast. A gentleman, Mr. Middleton, expressed his belief that it could now be forced open by any mechanic, but it required the assistance of four men to effect it, which took a half hour."

"A trial was then made on another safe, having the ordinary lock. Into the keyhole about three ounces of powder were placed. At the first explosion the door was blown off, and the safe thrown over on its side. The result was quite satisfactory as to the capability of these locks, and is highly creditable to Messrs. Milner, and proves incontestably the superiority of theirs to the usual locks."

I may observe, that if the lock in its perfect state would hold only one half ounce of gunpowder, it was simply impossible that the first explosion should have so "enlarged the cavity of the lock" as that the latter should be capable of containing one-and-a-half ounce.

To have inserted this latter quantity in the lock only proves that the first explosion had separated the lock from the door, thereby allowing the gunpowder not only to fill the lock, but to occupy the space between the front of the lock and the back surface of the door-plate. The above account cannot be reconciled in any other way.

The gentleman referred to as Mr. Middleton, whose acquaintance I made some time ago, takes a great interest in all matters relating to fire and thief-proof safes. After relating the above circumstance to me and reading the above account, he declared that instead of taking him half-an-hour to open it after the second explosion, it was only five minutes.

This result confirms an opinion I have always expressed upon these solid locks: their very construction assists the operator in blowing them open. There is nothing in the lock to give way, and consequently, the keyhole being plugged, some other part must suffer from the effects of the explosion.

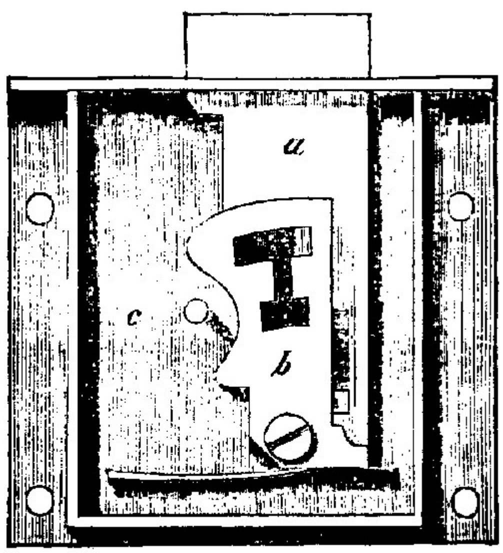

Figure 56. A 3 ½" ordinary six-lever lock, without gunpowder-proof arrangement. a, The bolt. b, The levers. c, The open space

The next is my own, as described earlier, and to assist in making this part of the subject as clear as possible, I insert accurate representations of all ordinary six-lever locks without a detector, and the same lock with the cellular filling, in accordance with the specification of my patent, dated January 31st, 1855. By adopting this simple contrivance, all lever, and most other locks, can be made powder-proof.

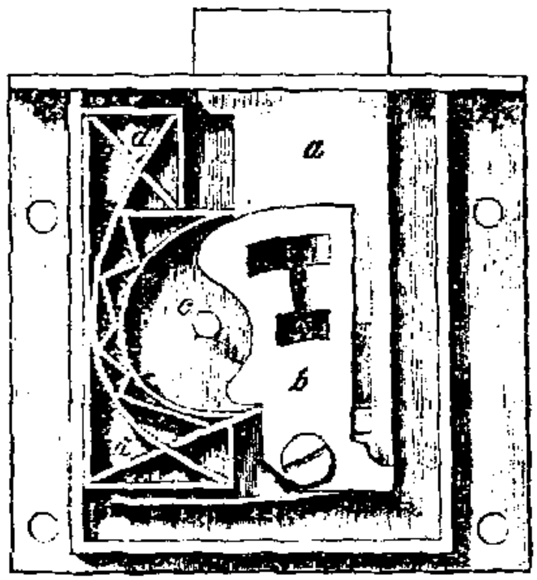

Fig.57. The same Lock, with my arrangement for making it gun-powder proof. a, The bolt. b, The lever. C, The space required for the key in locking and unlocking. Dd, The guard and cellular filling of the vacant space

Figure 56 shows the cavity that can be filled with gunpowder through the keyhole, and **figure 57** shows the guard encircling the

through the keyhole, and **figure 57** shows the guard encircling the space required by the key in locking and unlocking.

It will be at once seen that all the gunpowder that can be forced into the lock through the keyhole is the amount the space will hold. That is, supposing the safe is in a horizontal position, (for if it can be vertical, as most safes are), the gunpowder can only be inserted to the level of the keyhole.

Therefore, there is not the slightest advantage in casting the other parts of the lock solid; to the contrary. The locks, as now made by Chubb, Tucker and Reeves, and Gibbons, have a revolving "barrel and curtain," which, added to the before-mentioned plan, allows only a very small quantity of gunpowder being inserted in the lock.

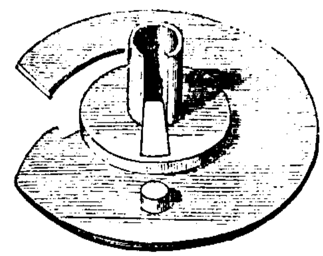

Fig.58. Barrel and curt Tucker and Reeves' Holdf

In addition to these contrivances, in the locks I use, there is a hole made on each side of the "cap" of the lock, as shown in **figure 59**, which causes the force of the gunpowder, when exploded, to lose itself through these apertures.

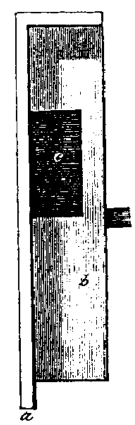

Fig.59-End view of Po Lock. a, The back pl cap. C, The aperture

To make assurance doubly sure, and especially as my statement differs so widely from Mr. Milner's, in May, 1856, I fixed a 3 ½" Gibbons' patent detent till lock, fitted with my patent powder-proof contrivance, on the door of a 26" safe, and charged the lock several times with gunpowder, rammed in as tight as possible to plug the keyhole.

After firing it, the result was that with the exception of the works of the lock being, "furred," both it and the safe door were perfectly uninjured. In each trial, the safe was laid on its back and well shook, so as to get as much powder in as possible.

Chubb's plan is to perforate with numerous holes the back plate of the lock, as shown below.

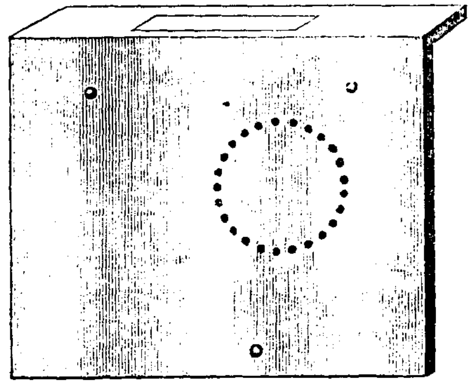

Fig.60. Chubb's Detector Lock, with powder-proof contrivance

Cotterill's Climax Detector Lock is gunpowder-proof in itself. The next powder-proof lock is Tucker and Reeves's Holdfast, which, also, is gunpowder-proof in itself (see **figure 61**).

It will be seen that the key moves inside the levers or slides, the latter being separated by pieces of metal. It is simply impossible to damage this lick, even when it is in a horizontal position, by ramming it with gunpowder, and exploding it.

I have tried to do so with one of them by ramming it with gunpowder, and with the keyhole with a blank key, leaving a minute prime-hole at the end of the bit. Though the charge exploded with the report of a gun, and the lock had been tested several times before in the same way, it proved, on examination, to be uninjured and easily answered to its key. I am quite convinced that both this and the lock shown in **figure 57** may be charged and fired a hundred times in succession without enabling the operator to open the safe.

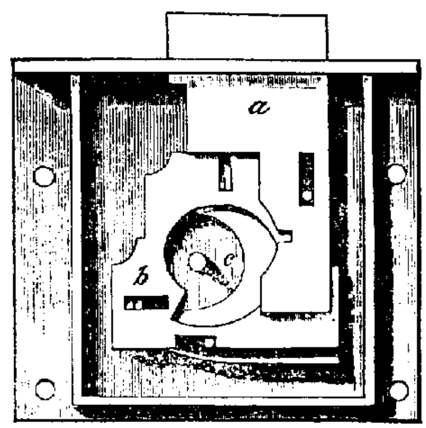

Figure 61. Tucker and Reeve's Holdfast lock, with the barrel and curtain away. a, The bolt. b, The slides or levers. c, The space for the key to lock and unlock

It is but right to state that it is only the "old" locks, as described by Mr. Milner, at Liverpool, which have been blown open with gunpowder.

I am not aware (and I have made numerous inquiries) of a single

instance in which a safe, secured by a modern 3 ½″ or 4″ six-lever lock, has been opened by a thief filling the small lock through the keyhole, with gunpowder.

The box of wards or other locks, by being screwed to the back plate of the lock-case, as shown in **figure 4**, leaves a space of ½″-1″ between the face or cap of the lock and the back surface of the door-plate. This allows gunpowder to be freely poured through the keyhole into the lock-chamber, and most lock-cases will hold from five to thirty pounds' weight of gunpowder, according to the size of the safe-door. However, the small lock is very different than the large lock-chamber, and must not be confounded with it.

By comparing **figure 57** with **figure 4**, an idea may be formed of the difference of internal capacity between the small lock and the lock chamber; the one holding from twenty grains to two grams of gunpowder, the other from five to thirty pounds.

Figure 23 and **figures 62-63** will illustrate the difference in the keys and keyholes of the old safe door locks, the box of wards and the modern ones, a three-and-a-half or four inch till.

Mr. Milner, in his characteristic style, publishes in his circulars, that "the various safes advertised as having powder-proof locks, may all (with the exception of Milner's) be blown open by filling the locks through the keyhole with gunpowder."

I last year invited Mr. Milner to prove the truth or falsehood of

I last year invited Mr. Milner to prove the truth or falsehood of this modest assertion, by operating upon some of my safes with gunpowder; but for weighty reasons best known to himself, he did not accept the invitation.

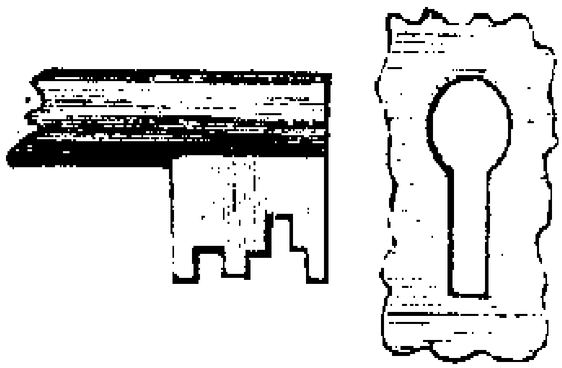

Fig.62. Key and keyhole of Tucker and Reeves' 3 ½"Holdfast Till-lock

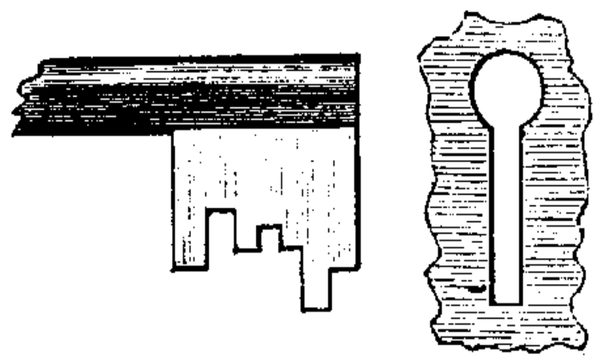

Figure 63. Key and keyhole of Chubb's 4-inch Iron-door Till lock

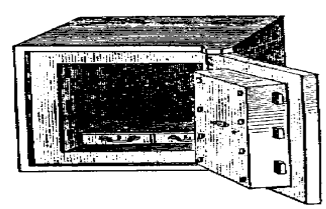
The liability of a well-made modern safe to be opened by means of gunpowder lies not so much in the small lock, as in the lock chamber into which a considerable quantity can be poured, and not through the keyhole.

In well-constructed safes this is prevented, except by drilling a hole in the door-plate, under the small lock. By adopting my patent case-hardened door and powder-proof lock-chamber, (**figure 28**) even that is effectively prevented.

It is in detached offices and in premises upon which no one resides during the night, or on the Sunday, and which are otherwise so isolated as to be out of the beat of the policemen or passers by, that safes are more especially liable to be opened by gunpowder.

As it must be particularly noticed, most of the safes which can be successfully operated upon by such an agent can be more easily opened, and without half the risk, by other means.



No accomplished thief or "cracksman" would attempt to open a safe by gunpowder in a private house or other inhabited premises, as the report of the explosion would be sufficient to arouse the heaviest sleeper. It must be remembered, also, that as the operator runs the risk of receiving personal injury by the experiment, it obliges him to keep at a respectful distance from the safe until all is over.

Soon after the fire at Newcastle-upon-Tyne, some burglars broke into the premises of Messrs. Leidemann, and by means of gunpowder blew up an iron-safe, but through the report of the explosion attracting the notice of the police, they were unable to secure any portion of the contents.

There has been so much “humbug” practiced with respect to fire and thief-proof safes, that it is necessary to make these remarks to induce those who possess really good ones to place reliance upon their security in this respect, although they may not have a specially constructed powder-proof lock.

A burglar would never run the risk of using gunpowder when, with most safes, he could effect his object by the chisel or drill. In detached offices he might use any means without fear of causing alarm, and in that case gunpowder would doubtless be the readiest, consequently, for such situations the safe lock should not only be powder-proof, but, above all, the door should be drill-proof, the safe itself of sufficient strength to resist the greatest violence, and, where practicable, it should be well secured in its position, or firmly built in the wall of the building.

CHAPTER ELEVEN: On the Comparative Prices of Wrought-Iron Fire-Resisting and Thief-Proof Safes

The majority of the lists of prices published by the different safe makers are quite unintelligible to the uninitiated and the general public. In some lists, the prices are given without naming the thickness of the iron-plates forming the

body and door; in others the price is given without drawers and partitions. The sizes in no two lists are exactly the same; neither do they state (with one exception) whether the plates are dove-tailed or riveted to angle-iron or both.

I conceived that the only way to get at the correct comparative prices of the various makers was to send to each a specification in accordance with the size and description of my “first-class safe," both with single and double doors. I therefore caused a copy of the following specifications to be sent to each of the respective makers, whose estimates are listed as:

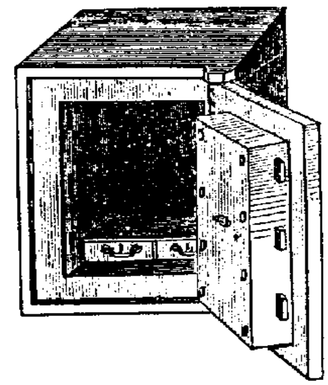


Figure 64. Price’s patent “f single-door safe. No. in 1 Size: 30 inches high, 23 in and 23 inches deep. 18 Pour if with patent case-hardene powder-proof lock-chamber, Sterling

No. I.- Specification for a single-door wrought iron fire-resisting and thief-proof Safe. Outer plates ¼” thick, to be both dove-tailed and riveted to strong angle-iron inside. The door to be 5/8” thick. The chambers for the fire-proof composition to be 3” thick. The knob to throw the bolts; to be secured by a patent unpickable and powder-proof lock. To be fitted with two drawers. Size: outside measure, 30” high, 23” wide, and 23” deep.

POUNDS	SHILLINGS	DENIERS
JOHN TANN, LATE E. TAN AND SONS 17	**0**	**0**
GEORGE PRICE 18	**0**	**0**
W. MARR AND SON 20	**0**	**0**
SAMUEL WHITFIELD 22	**0**	**0**
JOHN LEADBEATER AND CO. 23	**0**	**0**
CHUBB AND SON 23	**10**	**0**
THOMAS MILNER AND SON 24	**0**	**8**

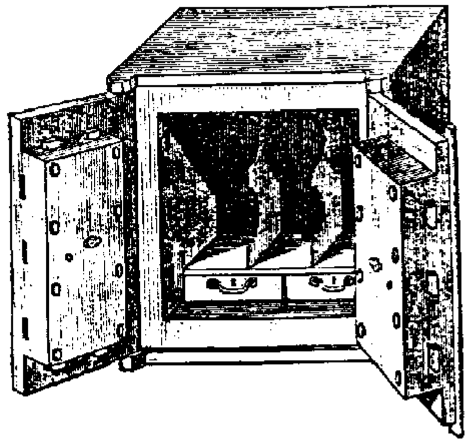

Figure 65. Price’s patent “first-class_ double-door Safe. No. in list, 102D. Size: 36 inches wide, and 24 inches deep. 31 Pounds Sterling. If with patent case-hardened doors, and powder-proof lock-chambers, 35 Pounds Sterling

No. II.-Specification for a double-door wrought-iron fire-resisting and thief-proof safe. Outer plates ¼” thick, to be both dove-tailed and riveted to strong angle-iron inside. The door to be 5/8” thick. The chambers for the fire-proof composition to be 3” thick. The knobs to throw the bolts; to be secured by a patent unpickable and powder-proof lock. To be fitted with two drawers, two partitions, and one shelf. Size: outside measure, 36” high, 36” wide, and 24” deep.

	POUNDS	SHILLINGS	DENIERS
W. MARR AND SON	30	0	0
GEORGE PRICE	31	0	0
JOHN LEADBEATER AND CO.	32	0	0
CHUBB AND SON	36	0	0

JOHN TANN, LATE E. TANN AND SONS 37	0	0
SAMUEL WHITFIELD 40	0	0
THOMAS MILNER AND SON 46	12	0

The estimates for the two safes, added together, give the following result:

	SINGLE DOOR SAFE P. S. D.	DOUBLE DOOR SAFE P. S. D.	FOR THE BOTH P. S. D.
GEORGE PRICE	18 0 0	31 0 0	49 0 0
W. MARR AND SON	20 0 0	30 0 0	50 0 0
JOHN TANN	17 0 0	37 0 0	54 0 0
JOHN LEADBETTER AND CO.	23 0 0	32 0 0	55 0 0
CHUBB AND SON	23 0 0	36 0 0	59 0 0
SAMUEL WHITFIELD	22 0 0	40 0 0	62 0 0
THOMAS MILNER AND SON	24 0 0	46 12 0	70 12 8

These prices include Milner’s double patent powder-proof and door.

After noticing such a disparity of prices for the same article, my readers will naturally inquire how such a difference arises. Since I have been a safe manufacturer, it has been my endeavor to bring the manufacture in my own establishment to a system, and the result is that I can tell to a trifle the cost of every safe that leaves my works.

From the very limited number of safes and chests that can be made annually by a great number of hands, even with the aid of steam machinery, the profit on them is nominally very great, but in some of the before-mentioned estimates it must be excessive.

The weight of the single-door safe (figure 64) is 5 cwt. 3qrs., and the double-door (figure 65) 10 cwt, 1qr., which, allowing at the rate of 121£ Per ton for the iron and fire-proof composition, amounts for the two safes to 9l£ 12s., thus leaving a considerable balance as a margin for cost of labor, wear and tear of machinery and tools, locks, knobs, and other incidental expenses, together with the profit.

The principal item of cost is labor, and therefore it follows that safes can be made cheapest where labor is cheapest. The next item is iron, and the same remark equally applies. Since the rebuilding of my works, with sixty pairs of hands at full work, with the aid of the most approved steam machinery and every contrivance which ingenuity could suggest, I have only been able

to manufacture three hundred and ten safes and chests in a period of six months.

This will give an idea of the number that can be made by those who employ a greater number of hands. The cost of plant and machinery being so great, a fair allowance for interest of money on the outlay must be included in the cost of manufacturing a safe. Beyond this and the other items named, there is no important item of expense, except that of advertising, which, on such a limited and small return, must in some cases amount to something like twenty-five per cent on the cost of the safe.

As the general usefulness of an article is always enhanced by its comparative cheapness so as to bring it within the reach of all classes of society, it should be the object of all manufacturers to do away with all unnecessary and extraneous expenses, which must be paid for by the increased selling price of such article.

It follows that indiscriminate and extravagant expenditure of whatever kind, connected with the manufacture and sale of any article, must be paid for by a proportionate profit, which being paid by the purchaser, becomes a heavy and unnecessary tax upon the public.

We appear to be in such favor with indirect taxation, that it is seldom we inquire what is the proportion of the sum we pay for an article which goes for extraneous and unnecessary expenses; but if the retailer were to tell us that on a 20l£ article, 5l£ went for such expenses, we should be as uneasy and as dissatisfied as we are in paying a direct tax, such as the income and property tax. Yet in too many cases such is the fact.

A manufacturer, no matter of what article, who by purchasing his materials at the cheapest hand, who adopts machinery and economizes labor, who by careful management and being satisfied with a moderate profit, produces such article at a moderate price, deserves the support and encouragement of all liberal-minded men.

CHAPTER TWELVE: On Testimonials

"The upright man is guided by a fixed principle of mind, which determines him to esteem nothing but what is honorable, and

to abhor what is base and unworthy in moral conduct. He seeks no mask to cover him, for he acts no studied part: but he is, in truth, what he appears to be full of truth, candor, and humanity. In all his pursuits, he knows no part but the fair and direct one: and would much rather fail of success, than attain it by reproachful means. In his manners he is simple and unaffected; in all his proceedings open and consistent."

"No calculation of probabilities can insure safety to him who is acting a deceitful part."

"A man of enlarged capacity and extensive views is always upright. Craft is always the supplement of inferior abilities. It characterizes a narrow comprehension and a little mind"

"The man of moderation, as he is temperate in his wishes, so in his pursuits he is regulated by virtue. A good conscience is to him more valuable than any success. He can have patience. He can brook disappointments. He can yield to insurmountable obstacles: and, by gentle and gradual progress, is more likely to succeed in the end than others are by violence ` and impetuosity."

"In his highest enterprise, he wishes not to have the appearance of a meteor, which fires the atmosphere; or of a comet, which astonishes the public by its blazing eccentric course; but rather to resemble those steady luminaries of heaven, which advance in their orbits with a silent and regular motion. He approves himself thereby to the virtuous, the wise, and discerning: and by a temperate and unexceptionable conduct, escapes those dangers which persons of an opposite description are perpetually ready to incur."-*Blair.*

As the value of all testimonials depends altogether upon their accuracy and truthfulness, I must be allowed to express my dissatisfaction with the character of those generally circulated in connection with fire proof safes.

A testimonial, to convey a correct impression to the minds of its readers, should state not only the result to a safe after its exposure to fire, but **all** the attendant circumstances, such as:

- **The position of the safe in the building in which the fire occurred;**
- **How long the fire exerted its influence on the spot where the safe was situate;**

- **Whether it was built in a wall, or otherwise surrounded with masonry, or whether it was in a fire-proof closet;**
- **The room containing the combustible materials on which the fire fed;**
- **In an upper counting-house, or a ground-floor office;**
- **How long the fire had been about the safe before the fire-engine deluged its locality with water.**

If the contents are singed it should say so, and should not attribute such stains to essential oil or pyrolignous acid. If the fire was so slight that, the contents were only "slightly warmed," it should not state that the external heat was intense.

It should also state the exact appearance of the whole of the contents of such safe, when opened. It should not, like some witnesses whose integrity is questionable at a trial in a court of justice, state but part of the truth, withholding essential points of the evidence, but should state "the truth, the whole truth, and nothing but the truth."

There is no necessity for collusion misrepresentations, or the withholding of facts, as all that safe manufacturers can be expected to do is to make such a depository as secure against fire, thieves, and burglars as the laws of nature and science will permit.

Many safe makers declare their safes and chests will do too much more than is possible. The public can only require from inventors such results as are within the bounds of practicability and do not expect to see perpetual motion, or to hear of the actual discovery of the philosopher's stone. Those who offer such gratuitous results must not be surprised to be generally disbelieved, and witness their statements ridiculed and laughed at.

I am compelled to express my surprise and regret that men of the highest character and attainments should append their names to such documents. Such statements, contrary to their makers intentions, are only calculated to mislead the public. They place implicit belief in the truth of the statements therein contained, simply on the strength of such an array of influential and respectable signatures.

Before reading the following testimonials, selected from those published by the safe manufacturers whose names they respectively

bear, it may be well to inquire the meaning of certain words and expressions therein used, as follows:

When deeds are spoken of as having been preserved, it is invariably understood to mean parchment deeds, though in many cases the word "parchment" will be found omitted.

Where the word "seal" or "seals" is mentioned, it must be understood to mean "wax" seals.

"Perfectly uninjured" means that the material remained in its pristine state, after the depository enclosing it had been subjected to intense heat.

"Intense heat," "severe heat", "fierce fire," are synonymous terms, and mean red-heat, i.e. 1000°F.

"The iron was melted," when applied to wrought-iron, is a misnomer, as wrought-iron does not melt; it only fuses, and the lowest heat at which iron will weld being 12,777° F, it follows that such a temperature can only be produced by a blast.

"In immediate contact with the top of the chest" means that the articles touched the iron lining of the interior.

"Not in the slightest degree injured," when applied to wax seals, means that the sealing wax retained its impression; that it did not run or spread upon the surface of the deed.

"Perfect conductor" means that it has no power of transmitting heat.

A simple non-conductor only, when acted upon by fire, evolves no vapor, and is the opposite principle to that of "steam-generation," "evaporation," "vaporising," and "chemical filled" safes. The composition in all of these, on the application of external heat of 1000° F, generates steam.

Steam, unless under artificial pressure, is neither cooler nor hotter than boiling water; 212° F.

All safes, the chambers of which are filled with alum and sawdust, are thereby made fire-resisting on the combined principal of "non-conduction" and "steam-generation."

Many testimonials must be looked upon as the representations of various factories which one sees hung up at the principal railway stations. If the building has ten stories in the picture in order to arrive at the proper height, it will be necessary to take off five; and so with windows, chimney stacks, etc.

"Sir, I beg to inform you, that the patent fire-proof Chest which I purchased from you about eighteen months ago was exposed to the fire which destroyed No. 2, New Square, on Sunday last."

"The safe was full of deeds and papers. A few of the deeds which were in immediate contact with the top of the chest, and which appears to have been exposed to the fiercest heat, are in some degree injured, being shriveled in parts; but, I believe, will not prove to be illegible. All the rest of the documents, being more than nine-tenths of the whole, are quite safe and uninjured. I am sir, Yours faithfully, "JOHN MARTIN". P.S. The safe was exposed to the fire for a period of thirty-four hours."

This testimonial, which is doubtless so far correct as to confirm what I have before stated as to the impossibility of preserving parchment in an iron safe, whether made fire-proof as this was on the principle of non-conduction only, (see Marr's specification) or that of evaporation.

The injury to "a few of the deeds"(parchment) is not attributed to the natural consequences of intense heat acting on such a substance, "for a period of thirty-four hours," but to the accident of these deeds being "in immediate contact with the top of the chest."

As iron is one of the best conductors of heat, it is simply impossible to make a safe so hot that it shall injure deeds at the top, without in the same degree injuring those situated in other parts. It implies that the top plate of the chest was hot, while the others were cool. From some of the deeds being in immediate contact, i.e., touching the inner plate of the top of the chest, the latter must have been pressed full.

I presume the explanation is as follows: the chest, although in the burning premises for thirty-four hours, was subjected to heat but for a very short time. Short as it was, it was sufficient to "shrivel" the few deeds without injuring the other nine-tenths of the contents, which very probably consisted of paper.

"Color Works, 115, Upper East Smithfield, London, June 17th 1852.

Sir, the safe we bought from you, three or four years back was unlocked by us this morning, and all the books and parchments were uninjured. The safe was exposed to the fury of the fire from nine O'clock p.m., to eight o'clock, a.m., during which period not less than forty tons of oil and one hundred barrels of tar were consumed close to the safe. The safe was red-hot. Your Obedient Servants, THOS HUBBUCK & SON.

This Testimonial states that besides "the books" the "parchments were uninjured," although the safe was exposed to "the fury of the fire," and was red-hot for the space of eleven hours, "during which period not less than forty tons of oil and one hundred barrels of tar were consumed close to the safe."

How can this be reconciled with the previous one? In the former the deeds were "in some degree injured;" in this, "all the books and parchments were uninjured." The only solution is that the external heat was insufficient to "shrivel" the parchments.

Mr. Marr, in order to prove the fire-prove capability of his safes, subjected several boxes to an "experimental test."

"To ascertain their security, several of the boxes were thrown into furnaces, and allowed to remain there until they became red-hot; but the boxes and their contents, consisting of parchment and paper, were perfectly uninjured."

"The patentee begs to refer to Messrs. Evans and Co., of Queen Street, Cheapside; and Messrs Gladill, of Clerkenwell Close, in whose furnaces the boxes were thrown when the experiment was made, and which was witnessed by more than forty gentlemen."

The making of the outer plates of several boxes made fire-proof on the principle of non-conduction only, simply red-hot, and then withdrawing them, is no test at all of their fire-proof capability without keeping them red-hot for several hours in succession. In this "experimental test" the parchment is said to have been "perfectly uninjured, which is proof positive of the character of the test.

"24, High Street, Manchester, March 6th, 1854. Gentlemen, we have great pleasure in communicating to you, that the large "patent fire-proof safe" that we purchased from you twelve years ago for our late offices in New High Street, has been the means of preserving our books, cash, notes, etc.

Enclosed therein, on the evening of the 1st of March, our entire premises were destroyed by fire. The safe, after being subject to "fourteen hours intense heat, was unlocked on the morning of the 3rd of March, the locks all answering to their respective keys, and all the damage the contents received (water excepted) was that only some of the books were slightly singed at the edge. You are at liberty to make what use of this communication you may think proper. We are, gentlemen, Yours respectfully, Byland & sons.

If this is true, it is miraculous, as it is physically impossible for a safe made fire-proof with a simple non-conductor, as specified in Chubb's specification, to have preserved the contents from such slight damage, "water excepted," when subjected to "fourteen hours intense heat."

Does it mean that it took "fourteen hours" to ravage the "entire premises?" Where did the "water excepted," that damaged the contents, come from? Not from the fire-proof composition, as it contained no chemical material of a vaporizing nature.

If any fire-engines attended the conflagration, it does not appear that their water lessened the intensity of the heat 'outside' the safe; but it does appear that such water by some means or other got 'inside' the safe, "which was all the damage the contents received," except slightly singing the edges of the books.

"Store Street Mills, Manchester, May 16th, 1854. Gentlemen, we have the satisfaction of informing you that the fire-proof safe we purchased from you about three years ago for our premises in Store Street, (the counting-house and blowing-room of which were completely destroyed by fire last evening,) has secured the entire of our books contained therein, together with cash, notes, policies, etc.

This, to our astonishment, considering the intense heat the safe was exposed to from being built in the chimney flue. You are at liberty to refer parties to us, should any further particulars be required. We are, gentlemen, Yours respectively, Wr. Jones & sons.

In addition to the remarks made in reference to this safe and the fire, I may state that soon after its occurrence I mentioned to the gentlemen who attended the test of my safe in Lever Street,

Manchester, October 17th, 1854, the fact of the door of Chubb's safe, which was the only part subjected to the "intense heat the safe was exposed to from being built in the chimney flue," was "not fire-proof."

The representative of Messrs. Chubb and Son, being present, was appealed, and at once unhesitatingly confirmed the truth of my statement. What, then, is such a testimonial worth in reference to the fire-proof capability of the safe?

It preserved the contents simply from the circumstance of its "being built in the chimney-flue," i.e., every part of it was surrounded with masonry, except the door, which was not fire-proof. This consequently proves that a cast-iron safe, occupying the same position and subjected to the same "intense heat," would undoubtedly have preserved the contents equally well.

Doubtless many who delight in the possession of testimonials will say, "Better this than none at all." Be it so.

"A test of Tann's Patent Safes was made on the 13th of June, 1850, in the Islington Old Market, Liverpool, in the presence of the worshipful mayor, and numbers of gentlemen of the professional and commercial classes of Liverpool."

"The chest contained papers, a 50 Pound bank note, a 5 pound bank note, a silver watch, and a 'parchment' deed with four seals attached. After having been exposed to a severe fire consisting of forty cwt. of coal and other combustibles for three hours, the chest was removed and opened, when the whole of the contents were found perfect; the watch indicating the exact time."

"At the suggestion of several parties on the ground, the chest was subjected to a second ordeal for an hour, and with the same satisfactory result; a gold watch, deposited by a gentleman (a casual visitor), and several other articles of value were restored to the their respective owners as perfect as before the test."

"The parchment deed with the four seals was quite perfect, the impression on the wax being as perfect as when first deposited in the chest. An offer was then made by the representatives of the patentees to subject the chest to a further test, but the majority were of opinion that it was unnecessary, and that the chest had been subjected to a much more

severe heat than ever it could possibly meet with in any accidental fire. The foregoing facts are certified by the signatures of upwards of seventy witnesses."

The principle upon which these safes are constructed and rendered fire-resisting is based upon filling the spaces between the outer and inner surface with a chemical preparation (the discovery of the patentees). The basis of this composition is chemical salts, and thus it remains unaffected until the safe is exposed to a high temperature.

The chemical 'merely fuses' when the heat is increased to a degree at which most substances (except the metals) become decomposed. The 'water of crystallization' having been driven off, affords a great amount of vapor which is effectively condensed in the interior of the safe.

This keeps it at such a temperature that it cannot, even in the most powerful fire, be increased 'beyond that at which fusion takes place, until decomposition. This is an operation that would require a much longer continuance of heat than the destruction of the most substantial residential property would require.

This fact has been established beyond all doubt by the result of many experiments, attested by persons of the highest respectability, and in every trial to which the Reliance Safe has been subjected. Whether accidental or for the purpose of testing its qualities, it has proved to be perfectly secure against the action of fire.

The simple principle of steam-generation is here described in mystical and ambiguous language. Why not have stated simply that the "chemical salts" when merely fusing at a high temperature, 1000°, and becoming decomposed, part with the water of crystallization in the shape of steam or vapor, and that the temperature of the latter is 212°F, and that this temperature cannot, "in the most powerful fire, be increased" so long as the generation of steam can be kept up.

It must be observed that the annexed testimonial states that although "the chest had been subjected to a much more severe heat than it could possibly meet with in any accidental fire," yet, that "the parchment deed with the four seals was quite perfect, the impression on the wax being as perfect as when deposited in the chest."

"An extraordinary test of E. Tann and Sons' Patent Reliance Safes took place at Glasgow, on the 17th of October, 1850, in the presence of the superintendent of police, and a large number of the bankers, merchants, and tradesmen of that city. The safe was placed in the midst of 48 cwt. of coals and several wagons of wood, and was exposed to the action of the fire for three hours and a half. The result was quite satisfactory, as the testimonials underneath will testify."

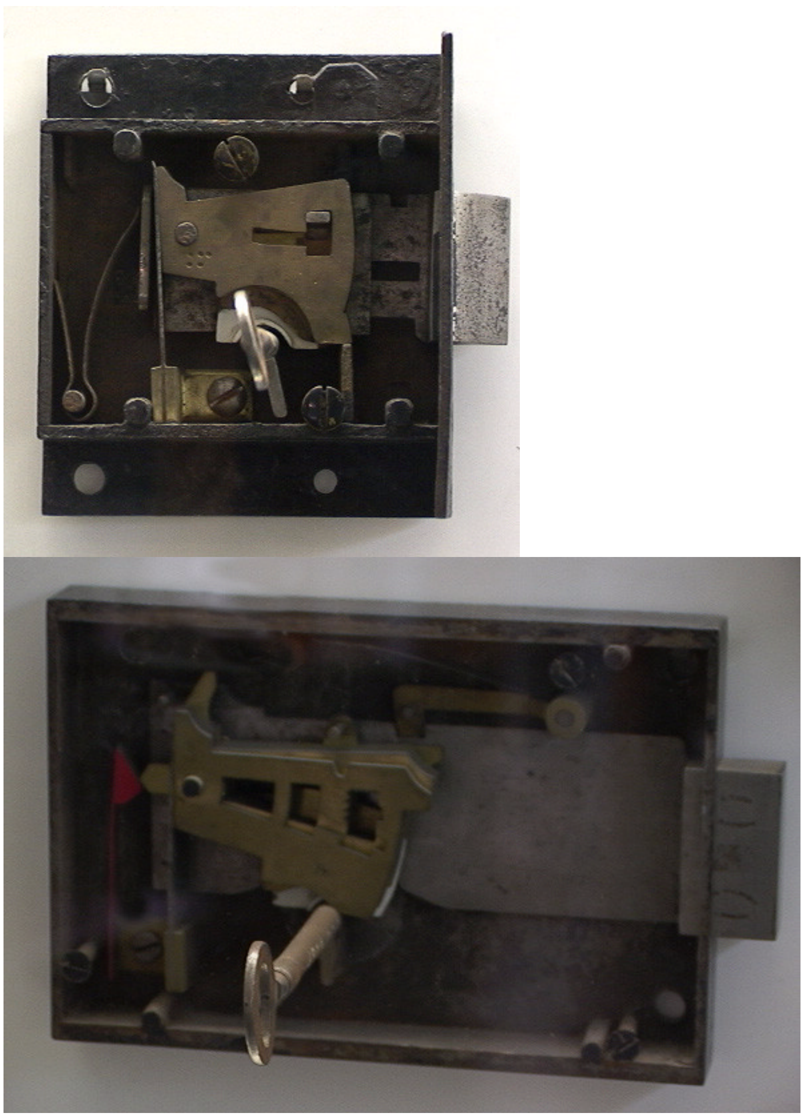

Figure GFP+1201 Tann's Reliance lever lock, circa 1843.

"Glasgow, October 15, 1850. Being present at the commencement of the advertised public test of the fire-resisting

qualities of E. Tann and Sons' (of the Hackney Road, London) Patent Reliance chemical filled safes, we certify that this document, with several books, bank notes, etc., among them parchment deeds with seals, and a watch was deposited in one of the safes immediately before being placed in the fire."

"We certify that the prefixed, and all other documents, watch, bank note, etc., placed in E. Tann and Sons' Patent Reliance Safe, prior to its being deposited in a testing fire, consisting of forty-eight cwt. of coals and several wagons of wood to prove its fire-resisting qualities, were, after a severe test of three hours and a half, found perfect as when lodged. (signed) James Smart, Superintendent of Police."

In order to perfectly understand the principle of vaporization, and the latter and following testimonials, I think it best to copy T. Milner and Sons' own explanation from their pamphlet, pages 8, 9.

"With reference to the superiority of this method of maintaining low temperature in the heart of a strong fire by vaporization, prolonged in chemical non-conductors, in other words, by substituting boiling for burning, it may be observed that from every pint of fluid discharged from the materials of the safe or box by heat into the interior, nearly two thousand pints of steam are evolved and condensed in the contents, rendering the whole mass damp and humid as a newspaper from the press."

By this means, 1000° of heat is neutralized and rendered latent and harmless, one-half of which temperature would destroy the contents of the best safe or box that can be put together of dry materials.

While the papers are made difficult of ignition, the whole process being conducive throughout to their preservation for a much longer period than that during which a box or safe would be in contact with fire in the successive conflagration of the parts of a building.

No greater heat than 212° will pass through this medium into the interior, a temperature perfectly harmless to books, papers, parchment, or even bank-notes.

The cause of the exhaustion of the moisture being so protracted, is its being sheathed and protected from rapid vaporization in

the absorbent non-conductor. In long continued heat, the nonconductor discharges its pyroligneous acid, which, combining with the alkali, forms a carbonaceous crust or pyrolignate of potass, the worst conductor of heat known.

From within this shelter, the papers or books slowly give out against the large volume of steam that has been passed into and condensed in them, reacting most favorably in keeping down their own temperature, that of the box or safe, and the surrounding, fire.

The tea-kettle, boiling at 212° in immediate contact with red-hot fire, into which a handful of bank-notes or gunpowder may be placed with safety, simply and aptly illustrates this principle. Another beautiful and forcible illustration of its extraordinary preserving capabilities may be shown in a very simple manner, by folding a piece of common writing paper into the form of a tea-cup, having a wire circle inside, and another outside, round the top, tied together with small binding wire, and two half-circles of wire crossing each other under the bottom, merely to keep the form.

If this paper boiler be filled with water, and put over a red-hot place on the fire where there is no smoke, it will boil away without even discoloring the paper. With great care, the boiler may be a bank-note; and with perfect safety, notes may be doubled up, and boiled in the water, with only paper betwixt them and red-heat, and afterwards dried.

As the inside of a loaf of bread in an oven is preserved for hours from being more than boiled, under circumstances wherein it would be reduced to a blackened, charred mass were it not for its own self-contained moisture. The most combustible materials are kept from injury in a similar but more perfect manner within these boxes, when surrounded with burning coal.

The same heat that would serve to make an iron safe red-hot in twenty-minutes will not bring the interior Milner's boxes, of one foot inside measurement (which dimensions are necessary for the full advantage of the resistance and reaction of this principle) to the boiling point, 212°, which cools down rapidly the moment the fire subsides around; whereas the red-hot iron safe remains an immovable burning prison for its dry contents, consuming them for hours after the fire has left them.

In short, the Milner's safe and the iron safe, standing near each

other in Messrs. Walker's fire, may be aptly compared to an oven and boiler in vigorous operation. In which of the two would you deposit a bundle of deeds, bank-notes, or gunpowder, with a view of preserving them from being burnt?

Within each of these depositories, a sentinel engine may be supposed always attendant and self-acting, ready not only to extinguish, but prevent fire, with its pipes charged and laid into the most valuable property which a public, professional, or mercantile office or private dwelling contains property uninsurable, and yet often exceeding in value all that is deemed needful to insure, the fire itself, in its first approaches, letting loose, and arousing, in concentrated operation within the box, its only efficient antagonist.

T.M. and S. have now briefly to allude to the insecure state of the monetary and documentary property of the country, from the custom-house, excise, and public offices, with their fire-proof (?) iron safes, strong rooms with iron doors, surrounded by piles of desks, cupboards, office furniture, and floors sufficient to make the safes and doors red-hot ten times over, burning them out with red-hot safety.

The banks and extensive professional offices, consisting of rooms, stories upon stories, whole piles of massive buildings full of wooden chests, drawers, secretaries, deed boxes, and iron safes and closets, little better, the whole property in which an hour’s strong fire would sweep into destruction.

Lastly, to the immense amount and value in commercial books and documents, without any more efficient protection than the worthless depositories which are sold as 'fire-proof,' without any rational claim to the quality of resisting fire.

It is as absurd so to denominate these gewgaw-looking things, like gilt bird-cages, as if fire had any respect for these things, as it would be to nail the old horseshoe over the door to keep out the fire-witch, instead of keeping her effectively out by giving the water-witch (the only fire-tamer!) scientific and permanent possession.

"Earnestly soliciting consideration of these remarks, T.M. and Son proceed to give the following testimonials:

"PUBLIC TESTING OF MILNER’S PATENT FIRE-RESISTING SAFES.”

"The triumph of science was completely shown by the result of the trials of Milner's Safe that took place in Messrs. Ransome and Sims's Old Foundry premises in this town, on Wednesday last, at eleven O'clock, to witness which a large influential body of gentlemen were present.

Two large fires were made in furnaces of bricks with flues all through, in one of which was placed a common iron Safe, filled with loose papers, and one of Milner's fire-resisting safes, also filled with books, papers, silver watch, gold, silver, and steel chains, with the half of a 100 Pound note.

The whole were inspected by the great body of gentlemen present, and locked down by Mr. S.H. Cowell, the Mayor. Fifteen minutes after being so placed, the cast-iron box burst from the great heat conveyed to each, while the patentees' chest firmly stood the test for two-and-a-half hours.

When it was opened, everything was taken out in such a perfect and uninjured state as to surprise and astonish all present. In a second furnace of similar construction was deposited Milner's Double Banker's Safe. After being filled by Mr. D. Wendon, the representative of T. Milner and Son, assisted by S. H. Cowell, Esq., and W.D. Sims, Esq. with the following articles, namely, the half of a 100 Pound note, several copies of various publications, including a beautifully illustrated edition of "Uncle Tom's Cabin," a casket of jewelry with gold and silver watches belonging to Mr. Read, jeweler of this town; a gold watch belonging to Mr. Dorling, a silver watch belonging to Mr. D. Wendon, a silver watch belonging to Mr. Baker, and others, the property of gentlemen present, with which was also a box containing several metals, to try the heat within, consisting of bitumen, iron, lead, zinc, by a scientific gentleman present.

This safe was allowed to remain five hours, during which time every exertion was made to increase the heat, the fire being superintended by four of Messrs. Ransome's men, and 1½ tons of coal, 50 cwt. of firewood, four large and three small hogsheads, several faggots, etc., were consumed.

At the time of opening the safe, the most intense anxiety prevailed; the company, including a great number of ladies for the town and neighborhood being very great. Every accommodation was afforded to give all parties a fair opportunity of seeing, a ring being roped round for the occasion.

Exactly at 4:45 P.M., the Mayor, with the gentlemen superintending, entered the ring and the safe was opened. On presenting its contents, the greatest delight and satisfaction they were evinced; each watch was correct to the time, being compared with the dial at the Old Foundry, no variation had taken place.

Every manuscript, book, paper, etc., was quite as perfect as when placed therein; the 100 Pound note was delivered to the Mayor, who exhibited it round, with all the other deposits, to the great assemblage, who at once expressed their entire satisfaction at the result of the experiments, and proceeded to sign testimonials recording the same.

We before briefly alluded to the common iron safe, which was also exhibited at the same time with the two patent safes from Milner's, and certainly presented a powerful contrast, the papers all being burnt to a calcined ash.

A slight discoloration appeared on the corners of one or two papers taken from the No. 1 Safe, which Mr. Wendon was glad to see, as it gave him an opportunity of explaining the same, being the essential oil form the non-conductor. This proved that however discolored, no injury is derived from the same.

At the close of these experiments, Mr. Wendon made a short address to the body of persons present, thanking the Mayor for his kind attendance and impartial attention; to which his worship replied, expressing his extreme satisfaction at the whole proceedings and heartily wishing so good an invention its deserved support."

A furnace of bricks, with flues all through, is a capital contrivance for conducting and driving the heat away from a safe, when under such circumstances it is subjected to fire.

When a half-note is deposited it is an evidence of doubt as to the capability of a safe to preserve it from destruction. All the newly published works, like "Uncle Tom's Cabin," are invariably bound in cloth, which, as previously stated, is not in the least injured by the steam; it being identical with calico, and is a vegetable production.

Bitumen or asphaltum melts at the temperature of boiling water, and therefore the remarks made relative to sealing was equally applicable to this mineral. Why is not the result to this and

the iron, lead, and zinc stated? Cast-iron begins to melt at 17,977° F. Lead melts at 594°, and zinc at 700°.

Instead of these, in order to prove the temperature of the interior during the fire, such articles should have been placed within that have a melting temperature that is lower than 212°. No parchment is named as having been in this safe.

The half-note during the operation appears to have grown into a whole one; all risk of its loss now being at an end.

This is a very clever idea of Mr. Wendon's, which shows his want of knowledge as to the properties of wood and essential oil. What is the difference between the stain of essential oil and a veritable **singe**? What is the distinctive name of this essential oil? Naphtha is distilled from wood by its total destruction. Essential or volatile oils require a temperature to raise them to a state of vapor, of 212°, which is in this case said to have been produced, and "discolored the covers of one or two papers." Yet it does not appear that the bitumen which melts at the same temperature (212°) did so.

London and Birmingham Railway Office. Easton Square, April 8th, 1844.

Sirs, I am instructed to send the enclosed report of the results of the public experiment on your Fire-proof Boxes and Safes at the Camden station of this Company, which was authorized by the Directors to be made under the immediate superintendence of their own officers, and to congratulate you on the complete success of the very severe trials by which you have allowed your admirable invention to be tested. I am, Sir, your obedient servant, R. Creed, Secretary.

"London and Birmingham Railway, Camden Station, April 8th, 1844. Mr. Bruyeres having requested me to superintend in person the trial of Messrs. Milner's Boxes and safes at this station, on Thursday last, I beg to report as follows:

"Early in the morning about one ton of coals and the same quantity of wood were piled upon a foundation of brick. Within the fire was placed a safe of double 2½" chambers, containing books and papers. The fire was lighted at half-past eight, and quickly burnt up. At the same time a placard describing the case as representing Milner's double-chambered Bankers' Safe was fixed in the ground. Double 2 ½" chambers shows that the chemical

composition is 5” thick."

“At nine O'clock a similar safe was placed in a similar fire, several gentlemen having previously placed inside some books, on which they had written their names, and Mr. Milner a ten pound note. A placard was again hoisted, Milner’s Double Chambered Safe, each chamber 1½". The fire burnt up to a great heat. The composition in this safe was 3” thick."

“A Deed Box was placed in another fire at 11:00 A.M., which had also been filled in the presence of a number of gentlemen. A brisk wind having blown steadily all day, the fires had from the commencement soon burned into an active heat, and this was especially intensely hot. A placard was again fixed near the fire, “Milner’s Portable Deed Box, 1¼”. The composition in this box was 2 ½" thick."

By this means the number of persons assembled having considerably increased, the cases were shortly after one O'clock removed and examined.

“First, the Bankers’ Safe, although taken out of a bed of red heat, the inner chamber and contents were, after five hours trial, quite cool and perfect as when put in. Next the double 1½” chambered safe was taken out and opened; its contents were found perfect like the first. The papers, including the ten Pound note, were only slightly warmed."

"The Portable Deed Box was then examined; when taken from the fire, parts of it were at a white heat on the outside, but the books and papers were all thoroughly steamed and preserved; some were slightly discolored at the edges near the cover, by the non-conductor, but all in a very good and sound state."

"The Bankers' Safe was again placed in a strong fire, and with two short intervals of a few minutes for examination, kept there until eight o”clock, when it was finally removed quite red-hot outside, but the inner chamber and contents perfectly fresh, and unaltered."

The severity of the test may be considered as far exceeding that of any ordinary fire. The perfect state in which the papers were found, after a trial of so many hours, should satisfy the most skeptical of the protective properties of the invention under the most trying circumstances. (signed) H. Wyatt.

This fire was lighted at 8:30 A.M., and the Bankers' safe was withdrawn at 1:00 P.M., consequently it was subjected to the heat arising from "one ton of coals and the same quantity of wood" for four-and-a-half hours. The *steam* in this safe was "quite cool." The second safe was in "a similar fire" for "four hours," and the "Portable Deed Box" for two hours.

All the three safes were made on the same principle, viz. that of steam-generation, and yet in the safe with the 3" composition, the contents are only "slightly warmed," while in the box with the 2½" composition, the contents are "thoroughly steamed." Steam is here represented as being of three degrees of temperature, on "quite cool", another "slightly warm," and the third its true degree, that of boiling water.

I cannot reconcile the plate of a safe becoming red-hot, which plate encloses a neutralizing vapor. Messrs. Milner illustrate this principle by "the tea kettle boiling at 212° , in immediate contact with fire, into which a handful of bank notes or gunpowder may be placed with safety," which, they say, "aptly illustrates this principle."

Also: "Another beautiful and forcible illustration of its extraordinary preserving capabilities may be shown in a very simple manner by folding a piece of common writing paper into the form of a tea-cup, having a wire circle inside and another outside round the top, tied together with small binding wire, and two half-circles of wire crossing each other under the bottom, merely to keep the form.

If this paper boiler be filled with water and put over a red-hot place on the fire where there is no smoke, it will boil away without even discoloring the paper. With great care the boiler may be a bank note; and with perfect safety, notes may be doubled up and boiled in the water with only paper betwixt them and red-heat, and afterwards dried."

Messrs. Milner blow hot and cold in the same breath. The paper or bank-note boiler does not get red-hot, neither does it burn; and yet, according to this testimonial, the red-hot boiler <u>does</u> get red-hot. What can anyone understand from these palpable contradictions?

The contents of these safes are said to have been preserved by steam at the temperature of boiling water, and yet the interior did not arrive at that degree of heat. The principle is

illustrated by a kettle boiling on a fire, and yet the outer plates of these safes, the kettles or boilers become quite red-hot outside, whilst "the severity of the test" of the Bankers' safe "may be considered as far exceeding that of an ordinary fire."

"Liverpool, May 24th, 1841.

"We, the undersigned, having this day witnessed the testing of one of Milners' fire-resisting boxes, by its having been placed in a large fire consisting of wood and upwards of six hundred-weight of coals, for the space of two hours and twenty minutes, do hereby express our conviction that the fire-resisting boxes manufactured by them are a perfect security in all cases of ordinary fire.

The box was filled with commercial and other books, papers, parchments, and deeds, (one of which, of the 16th Henry VIII. had five large thick-seals appended to it,) and, within an inch of the cover, several Bank of England notes; and previously to being closed, were submitted to the examination of J. S. Leigh, Esq., R. Frodsham, Esq., L. Graham, Esq., and others present.

The whole contents, on the box being taken out of the fire and opened in our presence, were found to be in a perfect state of preservation, the seals attached to the deed above mentioned not being in the slightest degree injured. This certificate is written on the deed of the 16th Henry VIII. Above mentioned, which was submitted to the test." (Here follow eight signatures.)

In all these testimonials, the amount of combustibles used for the fire, the time the boxes or safes were subjected to the heat, the articles enclosed, and their appearance when the safe or box was opened, should be particularly noticed.

Manchester, Jan. 20th, 1842.

"We, the undersigned, having witnessed the testing of one of Milners' new patent fire-resistant boxes, by its being exposed to the action of an open fire of wood and seven hundredweight of coals, for the space of one hour and a half, do hereby express our conviction that their new patent boxes afford a perfect security in all cases of ordinary fires."

"The box was filled with miscellaneous papers, an old ledger, and the deed on which this certificate was written, with

the seal attached. On opening the same, after it had been taken out of the fire, its contents were found to be preserved, and even the seal attached to the above deed was not in the slightest degree injured." (Here follow eight signatures.)

In the fire beside this box, the contents of a fire-proof box of another make were consumed." It appears an old ledger was put in this safe, which most likely was bound either in leather or forril. This, with the other contents, "and even the seal" of wax, were "not in the slightest degree injured."

Durham, 25th January, 1841.

"We, the undersigned, having this day witnessed the testing of one of Milners' Patent Fire-resisting Boxes, by its having been exposed to the action of an open fire of wood and coals for the space of an hour, do hereby express our conviction that the fire-resisting Boxes manufactured by them are a perfect security in all cases of ordinary fire. The parchment upon which this certificate is written formed part of an indenture which was in the box during the whole time of its being exposed to the fire." *(Here follow fourteen signatures.)*

The remarks previously made will apply to this and all the following testimonials, as all the latter state the same thing, viz., that the parchment and wax seals were in every case preserved uninjured, although the saving medium was a vapor of the temperature of boiling water, 212 °.

As the same element will always produce the same effects, I shall here copy from Milner's pamphlet another testimonial, and afterwards repeat the account of the test of one of my safes at Manchester, which, as before stated, was made fire-proof on the same principle and by the same means as those which were tested by Messrs. Milner in various parts of the kingdom.

"Gentlemen: A quantity of [parchment] deeds we had deposited in a common tin box at the Albion Bank, about a month since, were entirely spoiled, by water having gained access to the strong room; whilst, at the same time, and in the same situation, there were two or three of your fireresisting boxes also in the water; the papers in which were quite safe and dry.

I am, gentlemen, Yours respectfully," JAMES WENSLEY,

In the latter case it must be distinctly noticed that the

parchments were “entirely spoiled" by water" at the temperature of the atmosphere.

TESTING OF PRICES FIRE-PROOF SAFES.

An experiment was made on Thursday last, with the view of testing the fire-resisting qualities of a book safe, manufactured by Mr. George Price, of Wolverhampton. The trial took place in a yard near the Wesleyan Chapel, Lever Street.

The safe was a No. 8, being 28″ high, 22″ wide, and 22″ deep. The chambers are filled with a steam-generating composition, the moisture from which, on the safe being heated, is forced within, in the form of vapor, a principle which has been found to answer by other makers.

The door was fitted with one of 'Tucker and Reeves' patent safeguard locks," the two inner drawers being secured by Chubb's patent detector lock. Printed circulars were placed in the drawers, and six or seven volumes of books, chiefly ‘Slater's Directories,’ were arranged between the partitions above. There were also loose papers, blotting paper, a wood shaving, and, in addition to these, an account book containing the signatures of parties present, who were witnesses to the various articles being inserted.

Between the leaves of the account-book was inserted a five Pound note. A gold watch was also wrapped up in paper, and placed inside. The door was then locked and the key given to Mr. Councilor Warburton. The safe was raised in the center of the yard, upon two rows of bricks, (five courses) so as to allow the fire to act underneath it. Shavings, wood, and coal were then thrown around it, the wood being arranged conically so as to enclose the top of it, on which coal was also placed.

At a quarter to one O'clock the combustibles were lighted, and in a few minutes the safe was wholly enveloped in flame, which rose about two yards over the top, the heat compelling the spectators to retreat from its scorching influence. Mr. Alderman Heywood, Councillors Thackray, Thompson, Armitage, Worthington, and Howard, with agents of fire insurance Offices, and other gentlemen taking an interest in the matter, were present.

The fire was kept up burning until a quarter-past three o’clock, two and a half hours from the commencement, and was then withdrawn. Being extremely hot, it required to be soused with

water until four o’clock before it was sufficiently cooled to be opened.

It appeared to unlock with little difficulty, although the door was slightly warped by the contracting influence of the water. The brass handle seemed to have been partially melted, and broke on being pulled.

When the door was open, the contents presented the following appearance: The vapor, supposed to be at a temperature of 212° F., had dissolved the glue on the backs of the volumes, and thus loosened the leather. The wood shaving was a little darker, the edges of a few of the circulars were slightly discolored but most of them were not tinged, and the books, with the exception of being damped, presented no appearance of being near a fire.

The papers in the drawers, opened half-an-hour later, were also safe. The watch was going, and indicated four O'clock, but on being taken out, the sudden transition from heat to cold seemed to paralyze its energies, for it held its hands over its face, as if for protection, and refused to move.

The bank note, with the book enclosing it, were unsullied. The five members of the city council, named above, with a number of other gentlemen, placed their signatures to a document testifying their opinion of the fairness of the test, and stating the contents of the safe to have come out unscathed from the fiery ordeal.

We may remark that, so far as an artificial fire can be made to resemble that of a building, the test was a fair one. The conical mode in which the wood was made to surround the safe, threw the heat directly upon it, and from the length of time this was continued, the outer case must have been red-hot.

Indeed, the warping of the sides and door, and discoloration of the iron were sufficient indication of this. We understand that Mr. Price rests his claim to a share of public support on two points. The first is that he uses no solder, his objection to it being that it melts at a comparatively low temperatures, and then tends to allow the escape of what should be confined vapor. The second consideration is one of price, which will, no doubt, have its full weight with the public. (Manchester Examiner and Times)

It will be noticed that the size of the safe is here given, the time it was subjected to intense heat, the way in which it was

cooled before it could be opened, and the appearance of the whole of the articles after such a severe trial.

In addition to the facts already named, it may be well to state, that even after the cooling of the safe, the contents could not be handled. The watch which had been wrapped in a single sheet of paper was handed from one to another like a "hot potato," thus proving that the heat of the interior was that of boiling water, 212°.

Although the steam had "loosened the leather" of the books, it was apparent that whilst those in leather had their backs denuded of the cover, those bound in cloth were quite perfect. Another point to be noticed is that although the watch indicated the correct time on its withdrawal from the safe, yet to say it was uninjured would be to tell an untruth and deceive others; for, in consequence of the steam having entered the interior of the watch, the whole of the steel parts were oxidized the next day, and had to be replaced by new ones. This injury was the effect of the vapor, not the degree of heat, which is another reason why all such delicate articles should be first enclosed in a steam-tight box. It must also be particularly noticed that the watches in all the other tests came out perfectly uninjured.

By comparing this notice with those testimonials which precede and follow it, one of two alternatives is arrived at, viz., that either this or the others state the truth.

Hull, July 9th, 1841.

"We, the undersigned, having witnessed the testing of one of Milners' Fire-resisting Boxes, the same being submitted to a great heat from a fire in the Railway Bonding Yard, consisting of wood, coals, and coke, for one hour and fifteen minutes, do hereby express our conviction that they are a security in all cases of ordinary fire. The box was filled with books and parchments, part of which was the piece on which this certificate is written." (Here follow ten signatures.)

Nottingham, September 8th, 1841.

"We, the undersigned, having this day witnessed the testing of one of Milner's Patent Fire-resisting Boxes, the same being submitted to a great heat from a large fire of wood and coals, allowed by kind permission of Messrs. Bell and Corven, at their Iron Foundry, Beck Works, for one hour and twenty minutes, do

hereby express our conviction that they are a perfect security in all cases of ordinary fire. The parchment on which this certificate is written, with seal attached, was presented by John Buttery, Esq., Solicitor, and was in the box, with other papers and books, during the whole time of the above test." (Here follow six signatures)

Leicester, October 15th, 1841.

"We, the undersigned, having this day witnessed the testing of two of Milner's new patented safety boxes, in the Cricket Ground of this place, do hereby express our conviction that they are a great security in all cases of ordinary fires. The boxes were filled with papers, books, parchments, deeds, etc., and subjected to an intense heat, from a strong fire of wood and five hundred-weight of coal for one hour and fifteen minutes. The parchment on which this is written, containing the seal, was in the box the whole time of the test. ("Here follow nine signatures.)

Edinburgh, April 20th, 1842.

"We, the undersigned, having this day witnessed the testing of one of Milner and Son's Patent Fire-resisting Boxes, and its having been exposed to the action of an open fire of wood and coals for upwards of an hour, do hereby express our conviction that the Fire-resisting Boxes manufactured by them are a perfect Security in cases of ordinary fire."

"A considerable part of the Patent Box, previous to being taken out, was red-hot. A Box manufactured in Edinburgh, in imitation of Messrs. Milners', was tested at the same time, but not having arrived on the ground until the Patent Box had been nearly half-an-hour in the fire, it consequently did not undergo so severe a test. Both boxes were filled with account books, parchments, and miscellaneous papers and, on being taken out and opened in our presence, the papers in Milner's Patent Box were found to be in a complete state of preservation, while those in the spurious imitation box were nearly burnt to ashes. The parchment upon which this testimonial is written formed part of the contents of the box made by Messrs. Milner and Son." (Here follow eight signatures).

Glasgow, May 5th, 1842.

"We, the undersigned, having this day witnessed the testing

of one of Messr. Milner and Son's newly patented Fire-resisting Portable Safes, in the yard of Messrs. John M. Rowan and Co., Atlas Foundry, do hereby express our satisfaction and approbation that these Safes are calculated to preserve books, papers, and other property, in all cases of ordinary fire."

"The box was filled with books, papers, parchment, etc., and though it was exposed to the action of a coal and wood fire for an hour (thereby becoming red-hot), the contents were taken out in a perfect state of preservation. The parchment on which this testimonial is written formed part of the contents of the safe." (Here follow six signatures.)

Grantham, July 12th, 1843.

"Mr. D. Wendon, representative of Messrs. Thomas Milner and Son, new Patent Fire-resisting Box and Safe Manufacturers, of Liverpool, having announced by circular his intention of submitting some of these boxes to a public trial, we the undersigned beg to testify our approval of the principle, and satisfaction of their security in all cases of ordinary fire."

"At ten O'clock a.m. a fire was made in Mr. Green's yard adjoining the Duke of Rutland's premises, consisting of seven cwt. of coals, sugar hogsheads, a quantity of wood and shavings, and a barrel without its ends placed over the same, forming a chimney, and causing a very strong draft."

"At this period a round safe, in which was placed papers, parchments, and a small packet of gunpowder, also a deed box, nearly filled with books, papers, three parchment deeds, a watch, and pamphlets (upon which several gentlemen previously wrote their names) was placed in the fire, after being examined by the gentlemen present, and locked down by R. H. Johnstone, Esq., Mayor."

"At half-past twelve O'clock they were drawn from their bed of heat and opened, when the contents of the circular safe were as perfect as when put therein, the powder being quite cool and dry. The papers, etc. in the box were also preserved, and the watch marking off the time as though it had not been deposited. The circular on which the certificate is written formed part of the contents in the box during the whole time of the above test." (Here follow 21 signatures.)"

"In this test the "powder" is said to have been "quite cool"

in a temperature of 212°, and "dry" though it had been preserved by absorbing and condensing vapor evolved "by the chemical non-conductors," in the proportion of "nearly two thousand pints of steam" to "every pint of fluid discharged from the materials of the safe."

MILNER'S FIRE-RESISTING BOXES

A very interesting demonstration of the capabilities of these Boxes to resist heat took place in the City of Peterborough, at one O'clock on Tuesday last, in a spacious yard belonging to Mr. William Crisp, of Cumber-gate.

Perhaps nothing at the present time has so great a claim to public attention as this invention, warranting, as it does, in the common occurrence of casual fires, to preserve their contents uninjured. Certain, also, it is, that many opinions arising from the supposed impossibility of the thing will start in opposition.

In order, therefore, to remove such, and establish a confidence in the excellence of this patent, Mr. Thomas Milner, one of the patentees, and Mr. D. Wendon, representative of the firm, on their journey to Huntingdon, etc., waited for the purpose of publicly testing one, from the stock of Mr. J. Sawyer, their agent at Peterborough.

To witness the testing, a very large body of gentry and respectable tradesmen assembled. A Box was filled with papers and books; a parchment deed, dated 1657, with two very thick seals attached, belonging to John Broughton, Esq., Solicitor; and a five Pound Bank of England note, placed in by the patentee, and a very curious gold watch by Mr. Wendon, all of which were closely examined by the gentlemen above named, and locked down by P.J. Jenkins. Esq., Solicitor, who kept possession of the keys during the whole period.

At half-past one it was placed in a fire made for the occasion, consisting of a large quantity of coals, wood, shavings, barrels, crates, etc., superintended by Mr. Battersby, the foreman of the Gas Works. At twenty minutes to three it was removed and opened, when every thing deposited was as perfect as when put in.

The watch was set by Mr. Jenkins prior to being locked up, and when taken out was still going, not having varied scarcely a minute. Every person present was now satisfied that sufficient evidence had been shown fully to establish the principle; but on

a request being made for a second trial to ascertain how much more heat it would stand, the box and contents were given up to the parties, who placed it on the top of the fire, which was then at as strong a heat as could be made, every person exerting himself to put the fire on the box.

It was allowed thus to continue, until a general opinion that all was destroyed began to circulate, when it was again removed, and to the surprise, astonishment, and gratification of all, everything remained still uninjured, not even a discoloration or the slightest scorch, being perceptible. The gentlemen then signed the following testimonial:

"We testify our conviction that Milner's new Patent Fire-resisting Boxes are a perfect security in all cases of ordinary fires, and that the principle upon which they are manufactured is the best and most scientific ever brought before the public." (Here follow twenty signatures.)

Glasgow, May 7th, 1849.

"Gentlemen, we beg to inform you of the occurrence of one of the largest fires that has taken place here for many years. We send you, however, the Glasgow Herald, of this date which will give particulars, from which you will perceive that there have been a great many buildings burned down, a sugar refinery, a church, and several manufactories, including the extensive premises of Messrs. Charles Boyd and Son, soap and candle manufacturers."

"They had one of your No. 3 Safes, with drawers, got from us about five years ago; and the writer, upon calling upon them this morning, was perfectly astonished at the sight it presented."

"First of all, the brass knob, as well as the brass-work around the knob, was completely melted off, and the sides of the safe had blistered out nearly a couple of inches. The heat to which this safe has been exposed must have been tremendous."

"After enduring the fire above, it fell from the counting-house to the cellar beneath, and there it was exposed for hours to the most intense heat from the flaming oil and tallow. All the books and papers with which it was filled, and also notes to a considerable amount, wee perfectly saved. The large ledger, which must have been touching the door, was slightly discolored at the back-only; the binding, and no other

book was in the slightest degree damaged."

"On account of the absence of the principal this morning, the certificate of this splendid test of the complete and perfect resistance which your invaluable safes present against the ravages of fire will be obtained this evening."

“Thomas Milner and Son, with deepest feeling of gratification, lay before their friends, the public, the above extract from their Agent’s letter, reporting the strongest testimony they have received to the usefulness of their safes, and have equal pleasure in adding the promised certificate of the owners.”

This Testimonial is unquestionably of a very different character to the whole of those of Messrs. Milner and Son which have preceded it. But instead of admitting the liability to damage or destruction of the leather binding of books under such circumstances, the writer, perhaps in ignorance of the fact, to account for “only the binding” of “the large ledger” being “slightly discolored at the back,” jumps to the conclusion that it “must have been touching the door.”

“All the (other) books and papers with which it (the safe) was filled, and also notes to a considerable amount, were perfectly saved,” the whole of which, I presume, were in mid-air, like “Mahomet’s coffin.”

“As this safe was most severely tested,” how did it happen that none of the “books and papers” were stained by “the essential oil from the “non-conductor” which at the test at Ipswhich, in as severe a fire, “discolored one or two papers,” which Mr. Wendon was so glad to see, as it gave him an opportunity of explaining the cause.

I suppose that as this safe was “in long-continued heat, the non-conductor” discharged its pyrolignous acid, which combined “with the alkali,” and formed “a carbonaceous crust, or pyroliquate of potass,” and thus showed that it had a greater affinity for the “alkali” than for the “books and papers.”

It must be particularly noticed that this “ledger” was bound in either leather or parchment, as all “large ledgers” are invariably bound in one or the other. If the cause assigned for the discoloration of the binding is the correct one, it simply proves that the back-plate of the door must have been red-hot,

and consequently would have discolored the other papers and books in a similar manner. If the plate was red-hot, then it cannot be reconciled with the apt illustration of a kettle boiling on the fire.

Clyde-street, Anderston, Glasgow, May 7th 1849.

Gentlemen: At the calamitous fire yesterday morning, by which our premises and stock of oil, tallow, etc., were totally destroyed, our books were preserved in the Milner's Fire-proof Safe purchased from you. We have great pleasure in thus bearing testimony to the great efficiency of these safes. This safe was most severely tested; the brass knob and brass work about the lock were melted off. "Charles Boyd & son."

While commenting upon these testimonials, the amount of evidence against my hypothesis, viz., that it is a physical impossibility to preserve parchment, leather, and sealing was uninjured in a temperature of 212°.

The only means by which paper and books, bank notes, plate an specie can be preserved from destruction in an iron safe, when the latter is subjected to the influence of fire, appeared so overwhelming, that I began to doubt whether my senses had deceived me.

I immediately had a saucepan of boiling water brought to me, in which I placed two pieces of parchment, on one of which was a wax seal. The result was that the parchment immediately diminished in size one-half, and the wax seal ran and spread upon the decreased surface. In twenty minutes after the water had commenced boiling upon the fire, the parchment had lost two-thirds of its original dimensions, and the sealing wax remained in a liquid state, having lost all appearance of the impression it bore when first placed in the water.

This simple, effective, and interesting experiment can be tried by anyone with a vessel of boiling water, a piece of parchment, and a wax seal, and by folding a piece of paper and putting it in also, it will satisfactorily prove that the vaporizing principle has no injurious effect upon that material, although so destructive to the others.

For the purpose of procuring all the additional information on this very important subject, I wrote to Mr. Thomas Myers, of Gretton, near Uppingham, who carries on an extensive business in

the preparation of parchment skins, for his opinion as to the possibility of preserving parchment by vapor at the temperature of boiling water. He states in reply, that "Parchment will not stand either fire or water."

Conclusions

From the tenor of most of the before-mentioned testimonials, it will be gathered that leather, parchment, and sealing wax were preserved uninjured in a temperature of 212° F., in the various safes that were severally tested in different parts of the United Kingdom.

It will also be noticed that in my tests and experiments the contrary result has happened, although these safes were made fire-proof on precisely the same principle, Milner's patent, 1840.

It will be noticed further, that in one testimonial the parchments were "entirely spoiled" by simply water at the temperature of the atmosphere. Mr. Myers, from his practical knowledge of the substance of parchment and how it is affected by different temperatures, states, that it "will not stand either fire or water;" and, therefore, if the latter evidence is true, and I challenge its refutation, then the whole of the testimonials referred to, mis-state the real facts, and consequently lead the public to believe that such depositories will preserve these substances from injury when subjected to intense hear, at the same time that the contrary will invariably be the result, it being in accordance with a physical law of nature.

Admitting this to be so, then it follows that the appearance of these substances, when the safe is opened, is an infallible test of the severity and duration of the trial, for if they come out uninjured, it is a clear proof that little or no vapor has been generated, the fire having little power or intensity, and therefore that such tests are no tests at all, and that the notices and testimonials having reference thereto are deceptive, and therefore unworthy of credit.

BOOK TWO: On Locks and Keys

CHAPTER THIRTEEN: Early History

As, doubtless, thieving has been practiced in every age, it is only right to assume, that fastenings to the doors of apartments of some kind, by whatever name known, were employed from the earliest period of the world's history; but so little is known about them, that all is mere conjecture as to their construction.

Very little information can be gathered from, the works hitherto published, either in this or in any other country, relating to the early examples of the *manufacture Of* locks and keys, or to their *particular construction,* and there is the same dearth of information as to the lock-trade Of England in general, and that Of Wolverhampton in particular.

Mr. Tomlinson, in his "**Rudimentary Treatise on the Construction of Locks**," says, in the chapter "**On Locks and Lock Literature**" "The manufacture of locks, and a consideration of the mechanical principles involved in their construction and security, have never yet been treated with any degree of fullness in an English work."

This is so, as, although several locks invented in this country have been very minutely described and illustrated by engravings in the various foreign treatises on this subject, yet it is as Mr. Tomlinson says, "both in England and in America, men are more disposed to do the work than to describe it when done. In the 'Encyclopaedia Britannica,' in 'Hebert's Engineers and Mechanics Encyclopaedia,' in the 'Encyclopaedia Metropolitana,' in the 'Penny Cyclopaedia,' and in other similar works, locks are described as well as can be expected within the limits assigned to the articles.

Mr. Bramah's essay on locks, and on his own lock in particular, is one of the few English pamphlets devoted expressly to this subject. An excerpt from the proceedings of the Institute of Civil Engineers, in 1850, gives an interesting paper on locks by Mr. Chubb; and shorter reports of papers and lectures have been published in various ways. Perhaps the best account of locks which we have, considering the limited space within which great deal of information is given in a very clear style, is that contained in Mr. Tomlinson's 'Cyclopaedia of Useful Arts'.

The latter work, unfortunately, is only so far better than the others in respect to the description of locks, inasmuch as it gives a longer account of Chubb's than is contained in any of the former, and an account of the American locks introduced subsequently; otherwise, it is almost the same as the article on "locks" in the “Penny Cyclopaedia," which gives the most lucid description of the locks in general use up to the period when it was written, "within the limits assigned," of any work we have met with.

No one can question the *antiquity* of locks and keys, as there is abundant testimony to the circumstance of fastenings of this kind having been used for many centuries previous to the Christian era.

In Solomon's Song, chap. v., verse 5, this passage occurs: “I rose up to open to my beloved, and my hands dropped with myrrh, and my fingers with sweet-smelling myrrh, *upon the handles of the lock."* In Nehemiah, chap. iii., verse 3, is the following: "But the fish-gate did the sons of Hassenaah build, who also laid the beams thereof, and Set up the *doors* thereof, and the *locks* thereof, and the *bars* thereof." And these words are repeated in the 6th, 13th, 14th, and 15th verses.

It will be observed that in the previous quotations no key is mentioned; but in the following the key is mentioned in connection with the lock. In Judges, chap. iii., verses 23-25, “Ehud went forth through the porch, and shut the doors of the parlour upon him, and locked them. When he was gone out his servants came; and when they saw that, behold the doors of the parlour were locked, they said surely he covereth his feet in his summer chamber. An they tarried till they were ashamed; and behold he opened not the doors of the parlour; therefore they took a *key* and opened them.”

It may be well to notice in connection with these passages, that the word *“misgar”* translated “smith”, is rendered by Buxtorf “locksmith " in the following passage- Jeremiah, chap. xxiv., verse 1:

“The Lord showed me, and behold two baskets of figs were set before the temple of the Lord; after that Nebuchadrezzar, King of Babylon, had carried away captive Jeconiah, the son of Jehoiakim, King of Judah, and the princes of Judah, with the carpenters, and *smiths,* from Jerusalem, and had brought them to Babylon."

The most ancient lock ever discovered, is that described by Mr. Bonomi, as having secured the gate of an apartment in one of the palaces of Khorsabad. He says-

"At the end of the chamber, just behind the first bulls, was formerly a strong gate, of one leaf, which was fastened by a large *wooden lock,* like those still used in the East, of which the key is as much as a man can conveniently carry, and by a bar which moved into a square hole in the wall. It is to a key of this description that the prophet probably alludes, 'And the key of the house of David will I lay upon his shoulder;' and it is remarkable that the word for key in this passage of Scripture, ***muftah,*** is the same in use all over the East at the present time."

Figure 67. Egyptian Key

Figure 68. A Merchant of Cairo carrying the ke magazine

"The key of an ordinary street door is commonly thirteen or fourteen inches long; and the key of the gate of a public building, or of a street, or quarter of a town, is two feet and more in length. We have annexed a drawing of a key (figure 67) and the mode of carrying it (figure 68), alluded to in Isaiah. The iron pegs at one end of the piece of wood correspond to so many holes in the wooden bar or bolt of the lock, which when the door or gate is shut, cannot be opened till the key has been

inserted, and the impediment to the drawing back of the bolt removed by raising up so many iron pins that fall down into holes in the bar or bolt corresponding to the peg in the key."

The above discovery, and also the figure of one being sculptured among the basso-relievos of the Great Temple of Karnac, prove it to have been in use in Egypt for above four thousand years, during which period it does not appear to have underdone any sensible change. It was first described by Eton in his "Survey of the Turkish Empire," published in 1798 but it was not generally known in Western Europe, until the French invasion of Egypt, at the beginning of the present century, when a further account of it was given by M. Denon, in his great work on that country.

From a letter which appeared in the "Journal of Design and Manufactures," for July, 1850, p. 160, signed "W.C. Trevelyan," it appears that this pin-lock been found elsewhere than in the East; he says, "It is remarkable that the locks which have been in use in the Faroe Islands, probably for centuries, are identical in their construction with the Egyptian. They are, lock and key, in all their parts made of *wood;* of which material, if I mistake not, they have also been found in Egyptian Catacombs, and so identical with the Faroese in structure and appearance, that it would not be easy to distinguish one from the other."

It is said also, that a lock similar in character has been in use in Cornwall from time immemorial, which might have been introduced there by the Phoenicians.

Mr. Chubb says, in his paper on the construction of locks and keys, read before the Institution of Civil Engineers, April 9th, 1850:

"It is evident, however, that in the East, another lock and key, of a different description, were in ordinary use for fastening large doors and gates. There is nothing recorded as to the construction of the lock; but it can be inferred from the description given of the key, which is stated to have been in the form of a large sickle. Aratus, in order to give his readers an idea of the form of the constellation Cassiopeia, compares it to a key; and Huetius states that the constellation answers to such a description, -the stars to the north composing the curved part, and those to the south the handle."

"There is some curious information on this subject in

Parkhurst's Hebrew Lexicon. 'In the early ages,' he observes, 'they made use of certain crooked keys, having an ivory or wooden handle. These keys were placed in the holes of doors, and by turning them one way or the other, the bolt was moved forward or backward, in order to open or shut the door. This is evident from the testimony of Homer, where he says (Odyssey, xxi.) that Penelope wanting to open a wardrobe, took a brass key, very crooked, hafted with ivory, on which Eustathius remarks that this kind of key was very ancient, and differed from the keys having several wards which have been invented since, but that those ancient keys were still in use in his time."

"The poet Ariston, in the Antholgia, book vii, gives a key the epithet, *i. e., one that is much bent.* These crooked keys were in the shape of a sickle, according to Eustathius, but such keys not being easily carried in the hand, on account of their inconvenient form, they were carried on the shoulder, as we see our reapers carry on their shoulders, at this day, their sickles, joined and tied together. Callimachus, in his Hymn to Ceres, says that the Goddess, having assumed the form of Nicippe, her priestess carried a key, that is, *superhumeralem,* 'fit to be borne on the shoulder.'"

"It is most probable that the crooked keys' here spoken of were used to fasten and unfasten a simple horizontal wooden bar, moving into and out of a staple on the door-post, the key being inserted in a hole in the door, at some distance below the bar, and then turned to the right or left by its handle."

Very little information can be gathered from any published works relative to the locks used by the ancient Greeks and Romans. Most of the door fastenings of the former people cannot lay claim to the title of a lock.

Mr. Donaldson, in his work on ancient doorways, says, "the fastenings to the doors consisted of bolts, bars, and locks (Pessuli, Obiec Serae). Commentators are uncertain as to the time when keys were first used. Eustathius in his notes on the **x**th book of the Odyssey attributes the invention to the Lacedemonians: Pliny, vii. C. 56, on the other hand, gives the credit of the discovery to certain Theodorus of Samos. At all events, the use does not appear to be so remote as the Homeric Ages, for in the eighth book of the Odyssey, Ulysses is represented securing the rich and costly robes, vases, gold, and other valuable presents of Alcinous and his queen by a cord of rope fastened in a knot "closed with Circaean art.

The knot of Ulysses became a proverb to express an insolvable difficulty,; and a proof of the esteem in which the ancients held the art, so necessary in the absence of locks, maybe adduced from the Gordian Knot, famous in antiquity. And in fact Homer describes the treasures and other valuable objects as being kept in the citadel, secured merely by a cord intricately knotted. This, of course, was soon found to be a very insufficient protection, and therefore a wooden bar was adopted inside the doors of houses, to which it was attached by an iron latch, fastened or removed by a key adapted to it; this key was easily applied from within, but in order to get at it from without, a large hole was made in the door, allowing the introduction of the hand, so as to reach the latch, and apply the key.

The lock called the Lacedemonian, much celebrated by ancient writers, was invented subsequently; it was especially fitted for the inner chamber of houses, the bar fastenings continuing to be employed for closing the outer doors of dwellings and the entrance gates to cities. The Lacedemonian Lock did not require a hole to be made in the door, for it consisted of a bolt placed on that side of the entrance door which opened, and on the inside of a chamber door.

When a person, who was outside, wished to enter it, it was necessary for him to insert the key in the little hole, and so raise the bolt; and in time this species of fastening was improved by the insertion of the bolt in all iron frame or rim, permanently attached to the door by a chain, and fastening the door by the insertion of the hasp, through the eye of which was forced the bolt inside the lock by applying the key. Hence Varro lib vi de LL.- 'Nec satis reserare ab sera dictum, id est aperire. Hinc etiam Serae, quibus remotis fores pandunter. As also Nonius in Patibulum-‘Sera sua sponte delapsa cecidit, reclusaeque subito fores admiserunt intrantem.'

Thus it appears that the locks of the ancients were not of the same constructions as ours, not being inserted or morticed into the doors, nor even attached except by a chain, and being in fact mere padlocks.

Lipsius, in his comments on the second book of Tacitus, is the first to allude to the ancient usages respecting keys, some of which he states to have had a ring the size of the little finger, for the purpose of being worn and engraved so as to answer the purpose of a seal. Garlaeus, in his Dactyliotheca, gives in his

forty-second subject an example of a key with a ring attached to put on the filter; the ring has an onyx engraved with the helm of a vessel between two ears of corn, in allusion probably to the occupation of the wearer, who may have been engaged in the importation of corn from the provinces: the wards of this key, given by the learned Antwerpian are precisely similar to those of the present day; and numbers 205 to 209 inclusive are other keys with rings. There are several specimens of keys among the bronzes of the British Museum.

"The bolts (pessuli) were generally two to each door, as Plautus 'Ostium ambobus occlude pessulis; Aulularia;' for which reason the ancient writers generally use this word in the plural number. The reader will have observed that frequent reference has been made to passages taken from the Odyssey which abounds in allusions to the domestic habits of the Greeks, it being a picture of the domestic manners of the ancients, as the Iliad is of their public life and usages."

We shall here insert a passage forming part of the last paragraph to the second book of the Odyssey. Telemachus, after an angry debate with the suitors of Penelope, has retired to his chamber, attended by his old faithful servant, 'the sage Eurycleia.'

"Whilst to his couch himself the prince addressed,
The duteous nurse received the purple vest:
The purple vest with decent care disposed,
The silver ring she pulled, the door reclosed;
The bolt, obedient to the silken cord,
To the strong staple's inmost depth restored,
Secured the valves."

When the gate was opened among the Romans, the folds (**VALVAE QUOD INTUS REVOLVANTUR**) bent inwards, unless it was granted to any one by a special law to open his door outwards; as to P. Valerius Poplicola, and his brother, who had twice conquered the Sabines ***(UT DOMUS EORUM FORES EXTRA APERIRENTUR),*** Plin. xxxvi. 15, after the manner of the Athenians, whose doors opened to the street ***(IN PUBLICUM***); and when any one Went out, always made a noise, by striking the door on the inside, to give warning to those without to keep at a distance. Hence CREPUIT FORIS, *concrepuit a Glycerio ostium,* the door of Glycerium hath creaked, i.e. is about to be opened; Ter. And. Iv. 1. 59. Hec. Iv 1.6. Plaut. Amph. I.2.34. This the Greeks called "vooelv Ovpav; and knocking from without kottelv, pulsare vel putare.

“The door, when shut, was secured by bars (obices, claustra, repagula, vectes), iron bolts,(pessuli) chains, Juv. Iii.304, locks (serae), and keys (claves). Hence abdere pessulum foribus, to bolt the door, Ter. Iieaut. Ii.3,37, occludere ostium pessulis, with tow bolts, one below, and another above; Plaut. Aul., I,2,25, uncinum immittere, to fix the bolt with a hook; obserare fores, vel ostium, to lock the door, Ter. Eun iv. 6,25, seram ponere, Juvenal, vi. 34, apposita janua fulta sera, locked, Ovid, Art. A. ii. 244, reserare, to open, to unlock, Ovid. Met. x, 384, excutere poste seram, Am. I.6, 24, etc. It appears that the locks of the ancients were not fixed to the panels (impages) of the doors with nails like ours, but were taken off when the door was opened, as our padlocks: hence *et jaceat tacita lapsa catena sera,* Propert. Iv.12,26.”

"That mechanical contrivances for securing doors, which were essentially locks with keys, were in use by the Romans, at a later period, is beyond question, “for the keys found at Herculaneum and Pompeii, and those attached to rings prove that a kind of warded lock must have been well known. There are the remains of a tomb at Pompeii, the door of which is made of a single piece of marble, including the pivots, which were encased in bronze, and turned in sockets of the same metal; it is three feet high, two feet nine inches wide, and four and a quarter inches thick; it is cut in front to resemble panels, and thus approaches nearer in appearance to a modern wooden door; and it was fastened by some kind of lock, traces of which still remain."

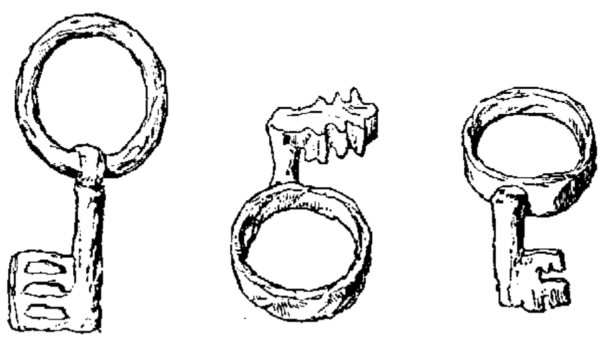

Figure 69. Bronze and Iron Keys from Pompeii and Herculaneum

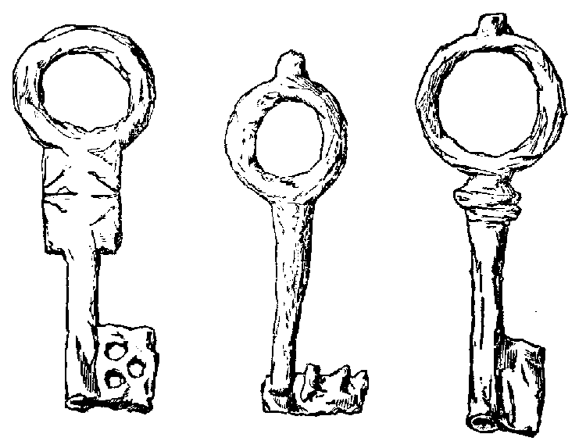

Figure 70. Bronze and Iron Keys from Pompeii and Herculaneum

In 1689, during some excavations in the plain at the foot of Vesuvius, where it was subsequently proved that Pompeii had

flourished, a workman observed the regularity with which successive layers of earth and volcanic matter had been deposited. He compared them to pavements one upon the other; with remains of burnt vegetation, charcoal, and common earth beneath each volcanic deposit. Under one of these dense masses of scoria, dust, and pumice stone, he found large quantities of carbonized *timber, locks, and iron work,* evidently the remains Of the inhabitants, which, together with some *old keys,* and inscriptions giving the name of the locality, satisfied the learned of the day, that they belonged to the ancient city of Pompeii.

In the garden was found a skeleton *with a key* by its bony hand, and near it a bag of coins. This is believed to have been the master of the house, who had probably thought to escape by the garden, and been destroyed either by the vapour, or some fragment of stone. Besides some silver vases lay another skeleton, probably of a slave.

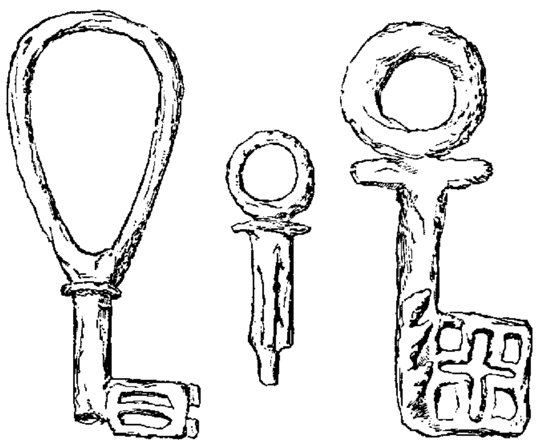

Figure 71. Bronze and Iron Keys from Pompeii and Herculaneum

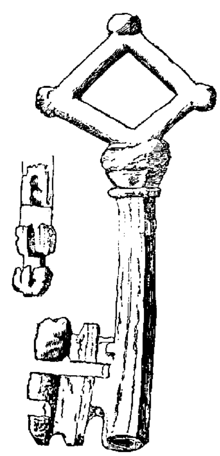

Figure 72. Copper key found

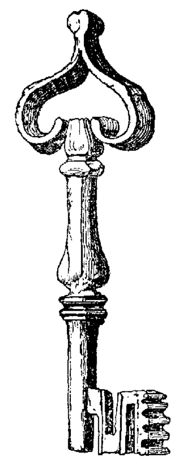

Figure 73. Early Key found at Mec Kent

The examples of Roman keys found in various parts of England and contained in the British Museum fully bear out the previous statement, and these, with the very beautiful specimens of the early English keys in the Museum at Marlborough House, being of such high interest, are well worth, and will amply repay, examination.

We may remark here that this important subject has not had the same attention and research of learned antiquaries which other

branches of science and art have received; and it is in part to this circumstance that so little can be said upon this interesting portion of our work. We may note that between the keys found at Herculaneum and Pompeii (figures 69, 70, and 71) and the Roman keys found in various parts of England (fig.72) there is a distinctive difference, although the whole of them belong to the same description of lock- the warded lock; and in the absence of any locks having been found, by which their particular construction might be ascertained, the shape of the cuts and holes in the "bits" of these ancient keys, prove beyond question, that in locking and unlocking, the key did not perform a complete revolution, and that consequently, they were identical with the spring locks of modern days.

It is remarkable, also, that the early English locks were constructed in a similar manner, as, will be apparent on a close examination of the *locks and keys* at Marlborough House. Several of the latter which were purchased at the Bernal sale are most elaborately and beautifully finished, and are the best specimens of any that have yet come under our observation, and prove that the locks were of the most complex character; and it may be fairly questioned whether they could be excelled either in ingenuity of design, or beauty of workmanship, by any of those, manufactured at the present day.

It was in the sixteenth century, in Germany, Italy, France, and England, that the art of the locksmith was at its highest perfection; and the keys were likewise treated, as M. de la Barte remarks in his interesting Catalogue of the DeBruges Collection,' during the 16th and 17th centuries, 'as absolutely artistic objects.' Nothing could be imagined more graceful than those little figures in the round, those escutcheons and armorial insignia, those ornaments and piercings, with which the end of the key was enriched; that part which is grasped in the hand, and for which we have substituted a common ring."

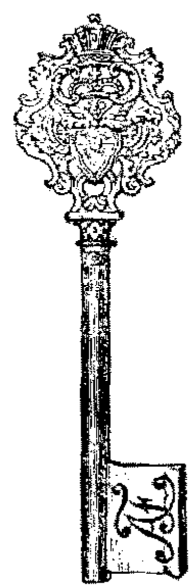

Figure 74. Old English Key

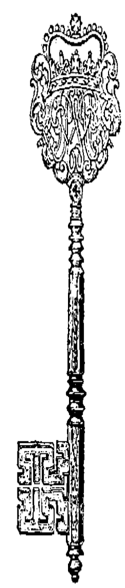

Figure 75. (
Ke

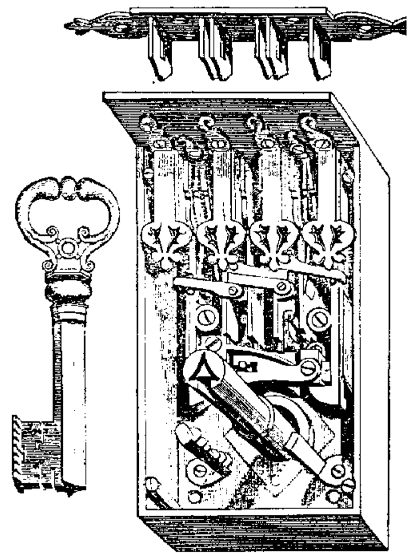

Figure 76. Old Elizabethan Link-plate Chest Lock

The English locks of this period are of such superior excellence in point of workmanship, that too high a value cannot be put upon the specimens now in existence, as they prove the advanced state of the lock manufacture in England three hundred years ago.

The Ornamental locks and keys which have recently been introduced, are mostly copies of those made in the sixteenth century, and as far as design and workmanship go, cannot claim superiority over the former.

Look at Figures 74 and 75, which represent two keys sold at the Bernal Sale. Can anything be more beautiful or artistic? Compare the modern "fancy bow keys" with these, and the superiority of the former will be at once apparent.

The comb-like nose-wards of the Elizabethan Keys are truly wonderful, and the tissue-paper thinness of the other wards are not less amazing. The iron of which these are made must undoubtedly have been of a superior quality.

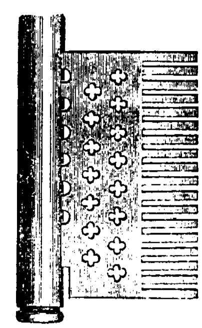

Figure 77. Old Engli
Marlborough House, pu
the Bernal Sa

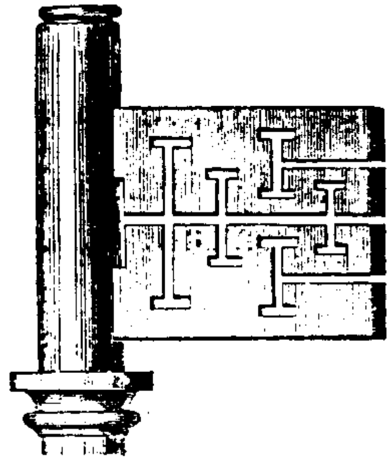

Figure 78. Old English Key found in the ruins of an Abbey

These ancient keys are variously composed of bronze, copper, or iron, and the variety of the locks corresponding thereto must have been as numerous as the modern ones.

The great antiquity of locks and keys being admitted, we shall, in the following chapters, describe and illustrate every principal lock which has been invented, from the wooden pin-lock of the Egyptians, to the most scientific and elaborately finished locks of the present time.

CHAPTER FOURTEEN: On the Old Locks and Keys

Master Index of Locks (chronological by date)

ROWNTREE'S LOCK, Patent dated February 23, 1790.
BIRD'S LOCK, Patent dated October 29, 1790.
FERRYMAN'S LOCK, Patent dated July 19, 1791.
BICKERTON'S SECOND LOCK, invented about 1792.
ODELL's LATCH, Invented about 1792.
MASON'S LATCH, Invented about 1796.
TURNER's LOCK, Invented about 1798.
PEDLEY'S LOCK, Invented about 1798.
BULLOCK's LEVER LOCK-BOLT, Invented about 1800.
ARKWRIGHT'S LOCK, Invented about 1798.
DAVIS'S LOCK, Patent dated April 11, 1799.
NORTON'S LOCK, Invented about 1800.
HOLEMBURG'S LOCK, Patent dated June 24th, 1801.
EAGLE's LOCK, Invented about 1801.
DOODY's LOCK, invented about 1804.
STANSBURY's LOCK, Patent dated May 18th, 1805.
THOMPSON's LOCK, Invented about 1805.
MACE'S LOCK, Invented about 1807.
COX'S LOCK, Invented about 1808.
ROBERTS' LOCK, Invented about 1809.
STUART'S LOCK, Invented about 1810.
TOMPSON'S LOCK, Patent dated December 29th, 1808.
ALPORT's LOCK, Invented about 1812.
DANIELL'S' LOCK, Invented about 1814.
GILES'S LOCK, Invented about 1814.
MITCHELL AND LAWTON'S LOCK, Patent dated March 7, 1815.
SCOTT's LOCK, Invented about 1815.
DEANE'S LOCK, Invented about 1815.
SOMERFORD'S FIRST LOCK, Invented about 1815.
RUXTON's LOCK, Patent dated May 14, 1816.
KEMP'S LOCK. Patent dated May 27, 1816.
SOMERFORD'S SECOND LOCK, Invented about 1816.
BURTON'S LOCK, Invented about 1816.
DUCE'S (SENIOR) LOCK, Invented about 1816.
TOY'S IMPROVEMENTS, Introduced about 1816.
HIGGINSON'S LOCK, Patent dated February 1, 1817.
GOULD'S LOCK, Invented about 1817.
LEES' LOCK, Invented about 1817
BRUETON'S IMPROVEMENTS, Introduced about 1817
CHUBB'S ORIGINAL LOCK, Patent dated February 3, 1818.
DYASS'S LOCK, Invented about 1818.
SMITH'S LOCK, Invented about 1818.
WRIGHT's LOCK, Invented about 1818.
STRUTT's LOCK, Patent dated October 18, 1819.

SPICER'S LOCK, Invented about 1819.
MALLET'S LOCK, Patent dated December 14, 1820.
AINGER'S LOCK, Invented about 1820.
YOUNG'S LOCK, Patent dated May 14th, 1825.
FRIEND'S SECRET LOCK, Invented about 1825.
RUBERRY'S BAG-IRON LOCK, Invented about 1826.
RICHARDS' LOCK, invented about 1827.
MACHIN'S LOCK, invented about 1827.
CHUBB'S COMBINATION LATCH, Patent dated May 7, 1828.
WALTON'S IMPROVEMENTS IN LOCKS, invented from 1828 to 1846.
GOTTLIEB'S LOCK, Patent dated June 21, 1829.
STANLEY's LOCK, invented about 1829.
CARPENTER & YOUNG'S LOCK, Patent dated January 18, 1830.
MORDAN'S LOCK PROTECTOR, invented about 1830.
WALTERS' LOCK, invented about 1830.
AUBIN'S LOCK, invented 1830.
RUTHERFORD's LOCK, Patent dated April 14, 1831.
BARNARD'S LOCK, Patent dated May 23, 1831.
YOUNG'S IMPROVEMENTS, Patent dated July 27, 1831.
PARSONS' BALANCE-LEVER LOCK, Patent dated December 20, 1832.
MACKINNON'S PERMUTATION LOCK, invented about 1835.
Dr. ANDREWS' (America) LOCK, invented about 1835.
MEIGHAN'S ALARUM LOCK, invented about 1836.
MARR'S LOCK, invented about 1836.
THOMPSON'S (SALLY) LOCK, Patent dated November 13th, 1838.
SANDERS' LOCK, Patent dated June 12, 1839.
NETTLEFOLD'S LOCK, invented by John Charles Schwieso, July 20, 1839.
GERISH'S IMPROVEMENTS IN LOCKS AND KEYS, Patented February 27th, 1840.
WILLIAMS' LOCK, Patent dated March 20, 1840.
PIERCE'S LOCK, Patent dated May 2nd, 1840.
WOLVERSON and RAWLETT ' Lock, Patent dated June 13, 1840.
BAILLIE 's LOCK, Patent dated December 23rd, 1840.
BROOKES LOCK, invented about 1840.
FOSTERS LOCK, invented about 1840.
PERRY'S IMPROVEMENT ITT FLUSH-BOLT LOCKS introduced about 1840.
BENTON'S LOCK invented about 1840.
COPE'S PIANOFORTE LOCK, invented about 1840.
HICKIN'S CIRCULAR ESCUTCHEON LOCK, invented about 1840.
WAKEMAN'S IMPROVEMENTS IN LOCKS AND ESCUTCHEONS, introduced about 1840.
DUCE (Junior's) LOCK, invented 1040, Patent dated May 24, 1842.
TILDESLEY and SANDERS LOCK Patent dated March 29 1841.

HANCOCK'S LOCK, Patent dated May 6th, 1841.
STRONG'S LOCK, Patent dated September 28th, 1841.
NEWELL'S (American) LOCK, invented in 1841. English Patent dated April 15th, 1851.
FIELDHOUSE'S IMPROVEMENTS, introduced about 1841.
ROCK'S IMPROVEMENTS, Patent dated Dec. 29th, 1842.
THOMAS'S PRISON LOCK, invented about 1842.
AUBIN'S LATCH-BOLT, invented about 1842.
TANN'S LOCK, Patent dated November 25th, 1843.
PITT'S IMPROVEMENT IN LATCH-BOLTS, introduced about 1844.
PICKIN'S IMPROVEMENTS, introduced about 1844.
CHESTERMAN'S IMPROVEMENT, introduced about 1844.
POOLE'S LOCK, Patent dated December 4th, 1845.
AUBIN'S SLIDE-STUMP LOCK, invented about 1845.
FELLOWES' IMPROVEMENT, introduced about 1845.
COTTERILL'S LOCK, Patent dated March 25th, 1846.
JONES' (American) LOCK, Patented in America about 1846.
DE LA FONS' IMPROVEMENTS, Patent dated July 6th, 1846.
CHUBB'S QUADRUPLE LOCK, Patent dated December 14th, 1846.
AUBIN'S CURTAIN-LEVER LOCK, invented about 1846.
BRIERLEY'S LOCK invented about 1846.
MORRIS'S DIRECTION PADLOCK, invented about 1846.
PLANTE'S Lock, invented about 1846.
TILDESLEY'S PADLOCK, Introduced in 1847
NEWELL'S IMPROVEMENTS, Patent dated September 28th, 1848.
YALE'S (America) LOCK invented about 1848.
WINDLE and BLYTH'S LOCK invented about 1848.
WILKES' LOCK, Patent dated May 8th, 1849.
JONES' LOCK, invented about 1849.
BRADFORD 'S LOCK, Patent dated July 22, 1850.
AUBIN'S BALANCE-DETECTOR LOCK, invented 1850.
AUBIN'S VIBRATING GUARD LOCK, invented 1850.
AUBIN'S COMPOUND LEVER LOCK, invented 1850.
TAYLOR'S LOCK, invented 1850.
BIGFORD'S LOCK, invented about 1850.
TUCKER'S CLOSED KEYHOLE SEPARATING-KEY LOCK, invented 1851.
RESTELL'S LOCKS, invented in 1851.
WOLVERSON'S LOCK, invented about 1851.

In the use of the word “old” at the head of this chapter, it may be proper to remark that we use it only to distinguish the whole of the locks which were in use previous to May, 1851, from the modern locks which have been in use since that period, and which

will be fully described in the chapter on modern locks.

We shall endeavor to describe the various locks mentioned with all possible regard to their chronological order, and also the usual modes of picking each variety as we proceed.

The first lock, of which there is any distinct account or representation, is the Egyptian lock, figure 79. These locks are described generally in Eton's Survey of the Turkish Empire, published towards the end of the last century, as follow: "Nothing can be more clumsy than the door-locks in Turkey; but their mechanism to prevent picking is admirable. It is curious thing to see wooden locks upon iron doors, particularly in Asia, and on their caravansaries and other great buildings, as well as upon house doors.

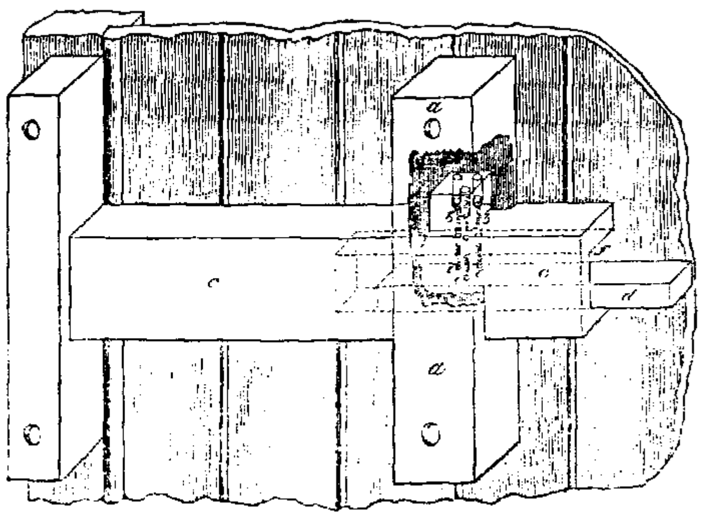

Figure 79. Egyptian Lock, copied from a wooden block recently brought from Alexandria.

The key goes into the back part of the bolt, and is composed of a square stick with five or six iron or wooden pins, about half-an-inch long, towards the end of it, placed at irregular distances. These answer to holes in the upper part of the bolt, which is pierced with a square hole to receive the key.

The key is put in as far as it will go, and then lifted up. The pins, entering the corresponding holes, raise other pins, which dropped into these holes from the part of the lock immediately above. They have heads to prevent them falling lower than is necessary.

The bolt, being thus freed from the upper pins, is drawn back by means of the key. The key is then lowered, and may be drawn out of the bolt to lock it again. The bolt is only pushed in, and the upper pins fall into the holes in the bolt by their own weight.

In respect to the **picking** of this lock, the main difficulty consists in obtaining any false key to correspond with the position of the pins. But this is easily accomplished in a manner analogous to that which is practiced in connection with other kinds of locks.

By laying a small piece of wax on a blank key and pressing it up against the holes, their **impression** would of course be left on the wax, thereby showing the position of the pins which furnish a guide to the fabrication of a false key that would open the lock. There is also little difficulty in picking it by a single instrument.

Although **warded locks** are next in antiquity to the Egyptian, after which followed those with tumblers, it must be particularly noticed that the Egyptian lock, in reality, lays claim to be considered as the type of all tumbler and most other locks.

The most essential part of all locks is the bolt, which can be shot backwards and forwards, locked or unlocked, only by its own key, and the greatest point of security that can be obtained in the construction of locks is that the possibility of effecting this purpose, by other instruments shall depend entirely upon chance.

It has therefore been the object of every inventor and manufacturer of locks that have any pretensions to security, so to construct them, that there shall be no possible means left by which the **particular form of the key(450)** or the requisite position of the security parts can be ascertained, except by having possession of the original or true key, or by an examination of the interior construction and arrangement of each particular lock.

Now although each of the great number of inventors of locks has produced one more or complex in character or new in form, nearly the whole of these innumerable ingenious contrivances for rendering locks unpickable may be classed under one or other of two systems of security.

Some consider that there are three distinct principles of

security exhibited in the numerous variety of locks, viz., the **fixed obstacles**, the **moveable impediments**, and the arrangement of the **letter lock**. Without questioning the propriety of such a classification, we prefer arranging the whole under two heads.

The first consists in inserting within the lock a series of fixed or **stationary obstacles(451)**, called wheels or wards. These are placed in and about the keyhole, or between the keyhole and the bolt, to prevent any other instrument than the proper key from having access to the bolt.

The second mode consists in the insertion of such **impediments to the retraction of the bolt(452)**, which are not fixed or stationary like the wheels or wards, but moveable and of various combinations, and which prevent other instruments than the true key opening the lock. To this class belong all the locks which have been invented, for the first Of Barron's, the patent for which was enrolled October 31st, 1778, downwards to the present year.

As before stated, the Egyptian lock is constructed on the latter principle, a consideration of which does not appear to have suggested itself to any inventor previous to the year 1778.

Barron was the first to improve upon this ancient principle, by affording additional security in the introduction of his double-acting tumblers. Most of the latter class are called either tumbler or lever locks, in contradistinction to the former. These two principles, vis., fixed or stationary wards and moveable wards or tumblers, may be applied separately or in combination.

Previous to the reign of James I, there is little or nothing on record relative to the inventions of our forefathers, as every inventor (no protection as we have under the patent laws) kept the secret of his invention to himself, in order to secure the monopoly of the trade to his own exclusive benefit.

On this account it is a most difficult matter to fix the date or introduction of any particular invention, not only in reference to locks and keys, but to nearly all scientific discoveries of whatever kind, as having taken place in any year, or even in any century. The moment protection was granted to the inventor, records of all the improvements in the arts and sciences which subsequently took place, abound.

Since that period, little difficulty exists for ascertaining the exact date of all meritorious inventions. From the above circumstances, it is not surprising that not a tittle of evidence can be found to prove whether the warded lock was the invention of any person in this kingdom or whether it was introduced from some other country.

The fact of its being of great antiquity is proved from "the representations of warded keys in early missals, and other works," since the commencement of the Christian era, and the keys preserved in the metropolitan and provincial museums. Beyond this, nothing more can be said as to its origin.

Before noticing the warded lock further, we will, for convenience sake, first describe the puzzle or letter lock, which, although not so ancient as the Egyptian, must certainly be considered as one of the oldest locks in use in Europe.

The **puzzle lock(453)** is generally in the form of a padlock, which is opened and closed without the use of a key, and which has certain difficulties thrown in the way of its being opened by any one who is not in the secret of the person who closed it.

It is, in fact, one of the locks in which the doctrine of permutation is made to contribute to the means of security. The key to open it is a mnemonic or mental one, instead of one of steel or iron. Two centuries ago, the puzzle lock attracted far more attention than any other. It has always contained certain parts, the movement of which constitutes the enigma. Some of these very curious and out-of-the-way locks are so formed as to receive the name of dial-locks; but chief among them are ring-locks, a name the meaning of which will be presently understood.

The puzzle or letter-lock of the ring kind, then consists essentially of a spindle, *d*; (figure 80) a barrel c encompassing the spindle; tow end-pieces, aa, to keep the spindle and barrel in their places; and the shackle b, hinged to one of these end-pieces.

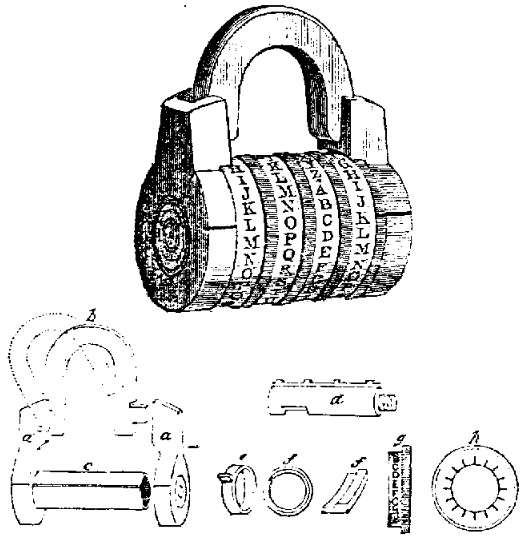

Figure 80. Puzzle or Letter Lock.

To unfasten the lock, one of the end-pieces must be drawn out a little, to allow the shackle or horseshoe to be turned on its hinge. The question arises, therefore, how this end-piece is to be acted upon. This is effected in a very ingenious way; there are four studs or projections in a row on the spindle d, and as the spindle fits pretty closely in the barrel, the former cannot be drawn out of the latter unless there be a groove in the interior of the barrel, as a counterpart to the studs on the exterior of the spindle.

Four rings, *e*, fit on the barrel, upon the interior of each of which there is a groove. Unless all four of these grooves coincide in direction, and lie in the same plane as the groove in the barrel, the studs will not be able to pass, and the spindle cannot be drawn out.

Each ring may easily be made to work around the barrel by means of the fingers, and to maintain any position which may be given to it. There are outer rings, g, one over each of the rings just described, with the letters of the alphabet (or a considerable number of them) inscribed on each. These outer rings, by means of notches on the inside, *h*, govern the movements of the inner rings.

The mechanical design of the lock is as follows; when the padlock is to be locked, the rings are so adjusted that all the grooves shall be in a right line; the spindle is thrust in, the end-piece is fixed on, and the shackle is shut down.

The padlock is now fastened; but a reverse order of proceeding would as easily open it again, and therefore the 'safety' or 'puzzle' principle is brought into requisition. **The outer rings(454)** are moved with the finger, to throw the various interior grooves out of a right line, and thus prevent the withdrawal of the spindle.

As each ring may be turned around through a large or a small arc, and all turned in different degrees, the variations of relative position may be almost infinite. The letters on the outer rings are to assist the owner to remember the particular combination which he had adopted in the act of locking; for no other combination than this will suffice to open the lock.

There may, for instance, be the four letters L O C K in a line, which line is brought to coincide with two notches or marks at the ends of the apparatus. Until all the four outer rings are again brought into such relative position as to place the letters in a line, the lock cannot be opened.

Vanhagen von Ense, in his Memorabilia, furnishes the following information regarding this lock and its inventor, Regnier. Speaking of M. Regnier, who was also the Director du *Musee d'Aruntilerie* in Paris, he says,

"Regnier was a man of some invention, and had taken out a patent for a sort of lock which made some noise at the time; everybody praised his invention, and bought his locks. These consisted of broad steel rings, four, five, or eight deep, upon each of which the alphabet was engraved. These turned around on a cylinder of steel, and only separated where the letters, forming a particular word were in a straight line with one another.

The word was selected from among a thousand, and the choice was the secret of the purchaser. Any one not knowing the word might turn the rings around for years without succeeding in finding the right one. The workmanship was excellent, and Regnier was prouder of this than he was of the invention itself. The latter might be contested.

I had a vague recollection of having seen something of the sort before, but when I ventured to say so, my suspicions were treated with scorn and indignation, and I was not able to prove my assertions; but many years afterwards, when a book, which as a boy I had often diligently read, fell into my hands, Regnier's

lock was suddenly displayed.

The book was called Silvestri a Petrasancta Symbola Heroica, printed at Amsterdam in 1682. There was an explanation at page 254, attached to a picture, with the following words:

Honorius de Bellis, seruloe innexoe orbibus volubilibus ac literatis circuscripst hoc lemma-sorte aut labore."

Honorius de Bellis wrote this inscription, by chance or by labor, around a lock composed of revolving rings graven with letters."

However, neither luck nor labor would have done much towards discovering the secret of opening Regnier's locks, from the variety of their combinations. Their security seemed so great that the courier's dispatch boxes were generally fastened with them."

This interesting extract which was brought forward by Mr. Chubb, in the paper before quoted, shows that the invention cannot be claimed by M. Regnier, as the above and other allusions to this kind of lock occur in authors who flourished two or three centuries ago.

In Beaumont and Fletcher's play of the "Noble Gentleman" the following lines occur:

"A cap case for your linen, and your plate, with a strange lock that opens with A M E N."

In the verses addressed to May, by Carew, in the "Comedy of the Heir," is the following passage:

"As doth a lock that goes with letters; for until every one be known the lock's as fast, as if you had found none."

But it does appear that although M. Regneir was not the original inventor of the letter-lock, he considerably improved it, as in the first example of this lock, supposed to have been invented by Cardan.

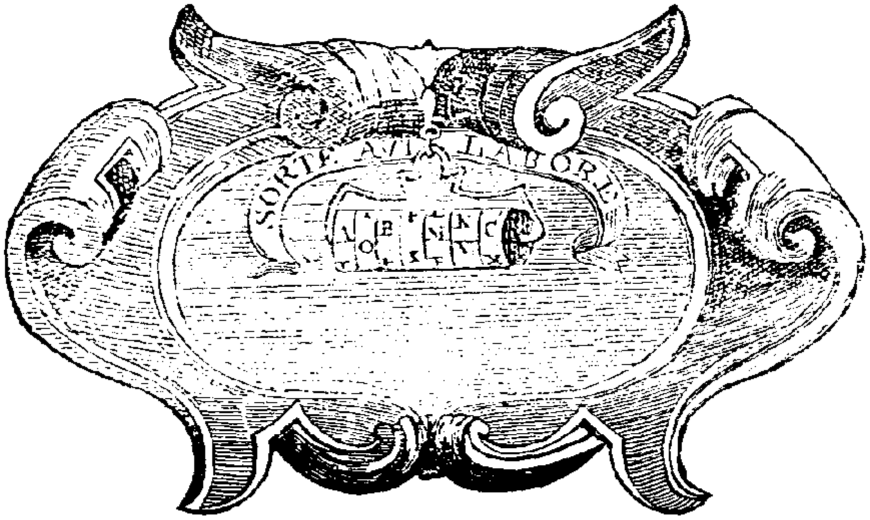

Figure 81. Puzzle-lock of the seventeenth century

Only one particular word or cipher could be used in each lock. **Regnier(455)**, to increase the chances of opening it, doubled all the rings, making each pair concentric, and enabling the user to vary the word at pleasure, by taking off the outer ring and placing what letter fancy chooses over the notch or groove in the inner ring, as contrived in all modern locks of this kind. (figure **80**).

In the work mentioned by Vanhagen, a copy of which is in the British Museum, is a drawing of a puzzle or letter lock (figure 81) which consists of a cylinder or barrel on which seven rings revolve. Letters are inscribed on each of these rings, and the ends of the cylinder are grasped by a kind of shackle.

During the progress of the "lock controversy" the following paragraph relating to this description of lock appeared in the *Observer*:

The French, in their exposition of 1844, availing themselves of the permutation principle, produced some marvels in the art; but the principle has not been adopted in this country.

The Charivari had an amusing quiz upon these locks when they first came out. It said the proprietor of such a lock must have an excellent memory: forget the letters and you are clearly shut out from your own house.

For instance, a gentleman gets to his door with his family, after

a country excursion, at eleven O’clock at night, in the midst of a perfect deluge of rain. He hunts out his alphabetical key, thrusts it into his alphabetical lock, and says A Z B X. The lock remains as firm as ever.

"Plague it!" says the worth citizen, as the blinding rain drives in his eyes. He then recollects that that was his combination for the previous day. He scratches his head to facilitate the movement of his intellectual faculties, and makes a random guess B C L O; but he has no better success.

In addition to his being well wet, his chances of hitting on the right combinations and permutations are but small, seeing that the number is somewhere about 3,553,578. Accordingly, when he comes to the three hundredth he loses all patience, and begins to kick and batter the door; but a patrol of the National Guard passes by, and the disturber of the streets is marched off to the watch-house”.

There is one adaptation of the principle of the letter lock, designed as an “escutcheon lock,” for securely closing the keyholes of locks on the doors of safes and strong rooms. Another modification is the dial lock, but both are too complicated and expensive to be generally used.

The escutcheon has long been a favorite resource with lock makers; various contrivances have from time to time been invented, more or less novel, and of various degrees of merit. But none of them when fixed to the doors of safes or such like depositories, can afford any security against the thief or burglar, from the circumstance of their being usually placed outside the surface of the doors, and consequently they can easily be removed by violence.

One of the first premiums awarded by the Society of Arts, after the commencement of their "Transactions," was to Mr. Marshall for a "secret escutcheon," in 1784, which invention was one of the many attempts which have been made to realize the properties of that “secret apparatus,” suggested by the Marquis of Worcester in his “Century of Inventions,” as follows:

“at page 69. A way how a little triangle-screwed key, not weighing a shilling, shall be capable and strong enough to bolt and unbolt, round abut a great chest, a hundred bolts through fifty staples, two in each, with a direct contrary motion; and as many more from both sides and ends; and at the self-same time,

shall fasten it to the place beyond a man's natural strength to take it away; and in one and the same turn both locketh and openeth it."

"at page 70. A Key with a rose-turning pipe and two roses pierced through endwise the bit thereof, with several handsomely contrived wards, which may likewise do the same effects."

"at page 71. A key perfectly square, with a screw turning within it, and more conceited than any of the rest, and no heavier than the triangle-screwed key, and doth the same effects."

"at page 72. An escutcheon, to be placed before any of these locks, with these properties; first the owner, though a woman, may with her delicate hand vary the ways of causing to open the lock ten millions of times beyond the knowledge of the smith that made it, or of me that invented it."

"Second, if a stranger open it, it setteth an alarum a-going, which the stranger cannot stop from running out; and besides, though none shall be within hearing, yet it catcheth his hand as a trap doth a fox; and though far from maiming him, yet it leaveth such a mark behind it as will discover him if suspected; the escutcheon or lock plainly showing what money he hath taken out of the box to a farthing, and how many times opened since the owner had been at it."

We cannot, of course, tell whether an "escutcheon or lock plainly showing what money" may have been "taken out of the box to a farthing" will ever be invented; but the locksmiths of Wolverhampton, in the sixteenth century, were celebrated for constructing locks that would tell "how many times" a lock had been "opened since the owner had been at it."

The **dial lock(456)** that is suitable for doors is made with one or more dials, each with a series of letters or figures stamped on it, and secured to the door. To each dial is a hand or pointer connected by a spindle to a wheel.

On each wheel inside the lock is a notch or groove which has to be brought to a certain position to allow the bolt to be withdrawn, also a series of **false notches(457)** to add to the difficulty of finding a proper notch.

In order to **change the relative position(458)** of the hand or

pointer to the true notch, a nut on the back of the wheel is loosened, and the pointer set at any figure or letter the parties using the lock may please, and it can be changed as often as they wish.

There is a very general belief that as these locks are susceptible of so many changes, they must necessarily be **secure against any skill or ingenuity(459)** that can be brought against them; but by a little further investigation, it will be apparent that they afford no further security than the Egyptian and the warded locks.

A dial lock was invented some years ago by William Brown, Esq., M.P., and was described in a paper read before the Architectural and Archaeological Society of Liverpool, in 1852. The following is an abridged account of it from a Liverpool paper of that period.

"As your Society are desirous of seeing any improvements or attempts at them, I send you a stock-lock for inspection. The idea for its construction I took from a letter-padlock. I had a lock of this description made by Mr. Pooley twenty-five years ago, which has been in use ever since on Brown, Shipley, and Co.'s safe.

Its **advantages(460)** I conceive to be as follows:

- **it cannot be picked, for there is no keyhole;**
- **it cannot be blown up by gunpowder, for the same reason;**
- **you cannot drill through the door so as to reach the lock, for you are intercepted by a steel plate on which your tools will not act; thus you cannot introduce gunpowder that way to force the lock off;**
- **you cannot bounce off the wheels in the interior with a muffled hammer, for vulcanized India-rubber springs resist this;**
- **you cannot drill the spindles out, as their heads are case-hardened;**
- **you cannot drive them in, for they are countersunk in the door about half-way through.**

"Now let us set the lock to the word "Wood" (any other four letters might be used). When you set the lock, make a private record of them, so that you may not forget them. If parties do not know your letters, nothing but violence, applied by some means or other, can enable them to get into your safe; for the

lock will not open to anything but its talisman. "

Take off all the large wheels and open the lock; you will see that the large wheels have a number of false chambers; if you get the spurs of the bolt into three real chambers and one false, you are as fast as ever, for all four must be right.

Having placed your key and pointer outside the door to point to W on brass-plate No. 1, the small wheel inside obeys the same impulse; then maintain your small wheel steadily on this point, and the large wheel No. 1, will only fit on at the right place, the true opening compartment being opposite the spur of the bolt.

It being necessary at the time you set your lock that it should be open, proceed with Nos. 2 and 3 in the same way; your pointer standing steadily at 0. No. 4 is the same, the pointer being held steadily at D. You should then shoot your lock two or three times, to be sure you have made no mistake.

Every time you shoot your bolts out, **turn your wheels(461)** away from the true chamber, and see when you again turn your pointers to " Wood," that your lock opens freely; it is the proof that you have made no mistake, and you may now venture to lock your safe.

When you unlock the door, and find it necessary to leave it open for a time, you should shoot the bolts as if locked, and turn the wheels, so that no one may find what your real letters are; and again adjust them to their proper places, in order that the bolt may go back and enable you to relock. Once having locked the door and turned the wheels from your real letters, you need not trouble yourself with carrying the key, but leave it in any place beside the lock.

"I believe two wheels would make a perfectly safe lock; three would be quite so. I adopted four to make security doubly sure, as it would be impossible in any given time to work the changes. On **two wheels by chance(462)** the lock might open; you can, however, calculate the chances against this; and also three or four, the false compartment on the outer rim being taken into calculation.

"If this lock is of any value, it should be known; if it has weak points, let them be pointed out, and they may admit of a remedy; for we ought not to be led to believe a lock is safe which is not so."

It be observed that Mr. Brown stated that his lock could not be picked because there was no keyhole; it being in this respect the same as its ally, the ring or letter lock. The same remark has been repeatedly made with respect to all the varieties of these locks.

They are unquestionably difficult to pick by merely turning the rings round and round, in order to hit upon the right combination, but can easily be picked on the **mechanical principle of applying pressure(463)** to the desired parts. It is only necessary to take a small piece of common wire, bend it in the form of the shackle, and put it between the ends of the lock; the spring or tension of the wire forces the ends apart, and causes the studs on the rod to bear against the rings.

On **feeling(464)** the rings, some of them will be found to bind, and by turning those that so bind, the notches or grooves are successively felt and brought into a straight line, and the lock is thereby opened. In a similar manner, the bolt of the dial lock is withdrawn, by feeling the “bind” or faction of the pointers, and the result is the same.

Not long after Mr. Brown made the previous statement, Mr. Hobbs was in Liverpool, and was taken to the office of Messrs. Brown, Shipley, and Co. to inspect the lock referred to. The safe door was closed and locked, and whilst Mr. Hobbs was explaining his views as to the construction of the lock, it immediately sympathized with his manipulation, so that the door was opened in a few minutes.

A puzzle or letter lock, which is really unpickable, was invented in 1855, by Mr. F. H. Wenham, of Effra Vale Lodge, Brixton, which obtained the medal of the Society of Arts in that year. (See the description of this lock in the chapter on modern locks.)

“We think it is probable that most nations have their ‘puzzle locks.’ There are several known by the name of Russian, Chinese, and Hindu puzzle-locks, some of which have the forms of various animals or birds, and they are locked and unlocked by pressing upon or moving some particular portion of their bodies.

The security of these locks, like the ordinary secret escutcheons, depends in most cases upon keeping the part to be pressed or moved, as secret. Some time ago there appeared in the Illustrated London News, the following engraving and description of one of the latter, which was so far secure in proportion to

the amount of reverence felt for the Hindu God it is supposed to represent.

“This curious Lock is in the form of a bird; probably, representing the Hindu god, Garuda, the carrier or bearer of Vishnu, the second of the Hindu Triad, Garuda being to Vishnu what the eagle is to Jupiter."

"Garuda is worshipped by the natives of Madras; and, his living type, a kind of large hawk, is diligently fed by the devotees: the writer has often seen the worshippers with little baskets, filled with flesh which is thrown skillfully, a small piece at a time, into the air, while they shout ‘Hari! Hari!’ a name of Vishnu, and the bird stoops on the wing and takes the prey."

"Garuda is supposed to possess divine intelligence, and is much revered. Many stories are told of his discernment and cunning; and it is, probably on this account that the native artist has made his lock in the form of Garuda, a sufficient guarantee, in his notion, for its acting as a safety or detector, equal, or even superior to the more mechanical and scientific inventions of Bramah or Chubb. We should add, that, in this Indian Lock, the keyhole is on the side, one of the wings of the bird serving as a shifting escutcheon."

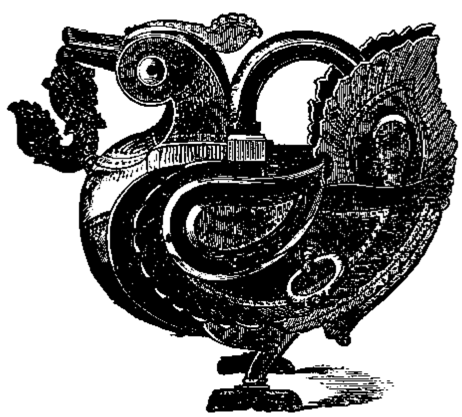

Figure 82. Indian Lock

In ordinary locks the **key(465)** consists of a circular shank with a loop-shaped handle at one end, called the bow, and a piece called the bit projecting from the shaft at a right angle at or near the other end.

The bit-end of the shank is, in the keys of locks which are to be

entered by the key from one side only, made hollow or tubular, hence called the pipe, to fit onto a pin or axis fixed in the lock.

In locks that are to be opened from either side, no pin can be fixed in the lock. In such a case, the shank is made solid and is prolonged beyond the bit, so as to enter and turn as in a socket within the upper part of the keyhole of that plate of the lock which happens to be farthest from the person applying the key.

The projecting bit, after being introduced into the body of the lock by a narrow opening (the keyhole), is turned round within the lock by a rotary motion imparted to the shank, until it comes in contact with a part of the bolt which is so shaped that the bit of the key cannot pass it to complete its revolution without shooting the bolt either backwards or forwards, as the case may be. When thus moved the bolt is retained in its position by a spring, or a tumbler, or by some other means, until it is again moved by the reverse action of the key.

The first and simplest means by which the entrance of a false key may be rendered difficult, is by giving a **peculiar form(466)** to the substance of the bit, and either adapting the form of the keyhole exactly to it, or inserting pieces of metal in the lock in such a way as to prevent the admission of a bit of different shape.

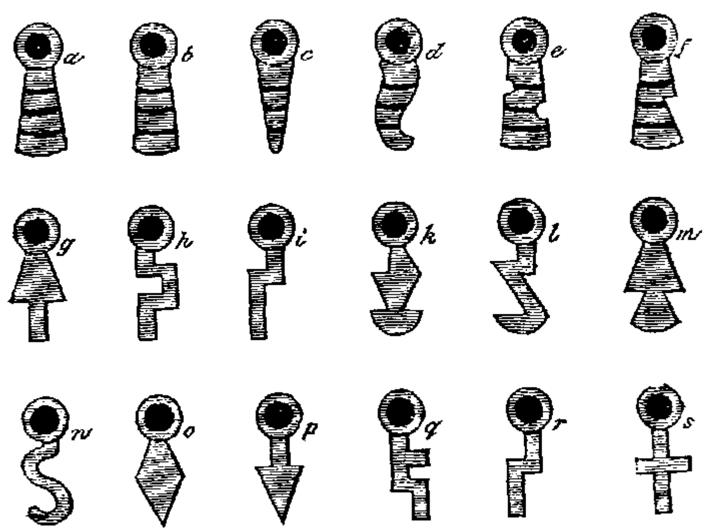

Figure 83. Fancy Bitted Keys

Fig.83 represents numerous forms of bits that are commonly used,

the keys, which are all represented as of the pipe or tubular make, being presented to the eye endways. Of these a b c and d are adapted for keyholes of various corresponding forms, while e and f, though suitable for keyholes of the same general form as the bit a, admit of further security by forming projections upon the sides of the keyholes, and also by forming the keyholes of the peculiar shape of the key bits g to s, the whole of which are cut through the front plate of the lock to fit the notches and grooves cut in the sides of the bit.

The next and principal means of security of the first class before mentioned is the use of pieces of iron or brass of various forms, fixed within the lock in such a way that no key can be turned round within it unless corresponding notches or slits are cut in its projecting bit. Figure 84, which represents a portion of the interior of the lock in isometric projection with the bit-end of the key in its place, will illustrate this. The tinted surface in this cut represents part of the back-plate of a lock with a tubular key turning upon a central pin in the plate.

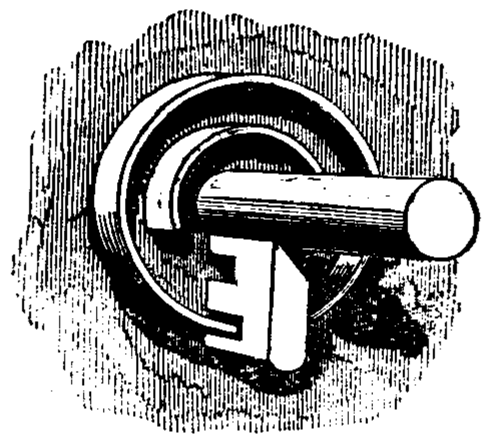

Figure 84. Key Bit and Wards

Attached to this plate are two concentric prominent rings of different degrees of elevation, one of which for the sake of variety is represented as complete or unbroken, while the other is cut away for a small space at the under side.

It is obvious that no key could be put into a lock provided with wards as in the cut, unless a **slit or notch(467)** were made in its bit to correspond with the larger and more prominent of the two rings, the round ward. It is equally evident that, although it might be put into the lock, no key could be turned round without having a notch also to correspond with the smaller and less

prominent circle, the short ward, which, being cut off near the keyhole, could not be discovered by an inspection from the outside of the lock.

In the common kind of locks, the wards seldom form a complete circle, but their effect is the same if they occupy only a small segment of it. They are commonly made of thin sheet iron, riveted to the plates of the lock. Locks with similar wards of copper are made for use in cellars and other places exposed to damp, where iron wards would become rusty.

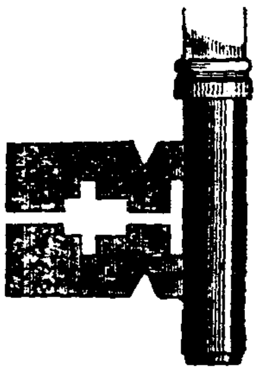

Figure 85. Key to Solid Warded Lock

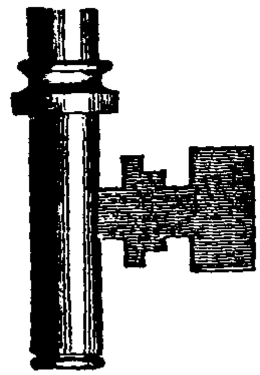

Figure 86. Key to Sash Warded Lock

A thicker kind of ward, known as solid wards, (figures 85-86) formed by casting in brass, and finished in the lathe, is used in many superior locks. Figure 84 represents wards of the simplest possible shape, which require nothing but a simple straight notch in the key to fit them. Many wards, however, are of a more complicated character, such as what are termed L, T, Y, and Z wards, from the resemblance of their sectional form to those letters respectively.

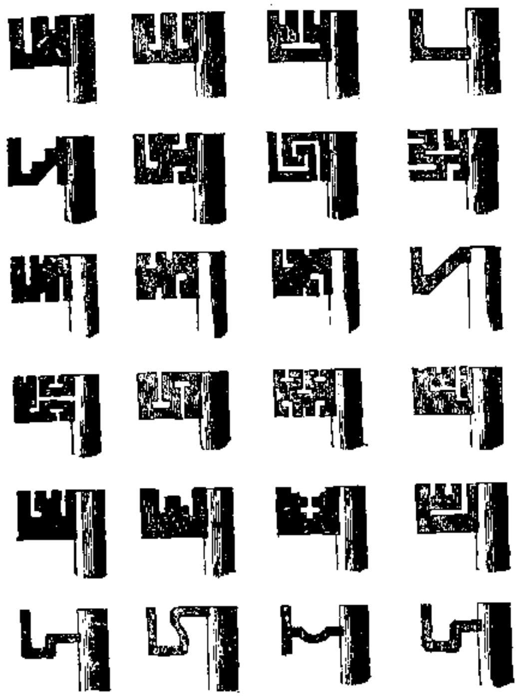

Figure 87. Keys to Warded Locks and ward patterns

There are also nose wards, top and bottom wards, step wards, bridge wards, etc.

By referring to the various forms of key represented in figures 85, 86, 87, and 88, the peculiar advantages and defects of that principle of security which depends upon the use of wards, may be readily comprehended.

The first and greatest defect of the system arises from the circumstance that, in ordinary cases, it is not absolutely necessary that a surreptitious instrument should perfectly thread the mazes of the wards. Thus the form and arrangement of the wards in the three keys numbered 1, 2, and 3 (figure 87) is so different that none of the three could be employed to open the other's lock, the first having two plain or simple wards, the second two L wards, and the third a T ward between two plain wards.

While these afford security against ordinary keys, they afford none whatever against a pick or skeleton key like 4 (figure 87), which would also open any other lock which is guarded merely by wards attached to the back-plate, as in Nos. 17, 18, 19, and 20; the only part essential to the moving of the bolt being the

extremity of the bit, which is retained in the skeleton key with nothing but a slender piece to connect it with the pipe or shank.

The security may be greatly increased by the use of other wards, attached to the opposite plate of the lock, and requiring notches in that part of the bit of the key which is represented by the slender connecting-piece in the skeleton 4. Such is the case in all the keys represented in Nos. 5 to 15 (figure 87) Number 5 represents a key for a solid-warded lock, which might, however, be easily picked by a skeleton key resembling No. 12.

The greater complication of the wards in No. 6 increases the difficulty of picking; while by the adoption of the arrangement shown in No. 7, the difficulty of introducing a false key is made perhaps as great as possible, since no instrument that does not thread all the intricacies of the wards could answer the purpose.

This form, however, requires very accurate workmanship, and unavoidably weakens the key to such an extent that it is in danger of breaking in the lock. All the keys represented in figures 83, 84, and 87, are pipe keys, adapted for such locks as have a fixed pin or axis, and can only be opened from one side.

It is, therefore, of no consequence that the wards attached to the back and front plates of the locks should resemble each other. In ordinary door locks, however, in which the key may have to be inserted from either side, it is essential that the wards attached to the two plates, if such be used, should either be precisely similar, or should bear such a relation to each other that notches may be cut in both sides, or rather in both edges of the bit of the key, to suit both sets of wards, it being a necessary condition that the two sides of the bit, marked a and b in the cut, (figure 88) should be perfectly alike.

In such locks, there is an intermediate plate, or bridge ward, which enters the opening marked c in the following figure, and which carries, on one or both of its sides, the principal wards. In many cases, the bit of a key divided by such an opening may be considered as constituting a double key, of which only one half is used at one time, that half being either a or b, according to the side through which the key is put into the lock.

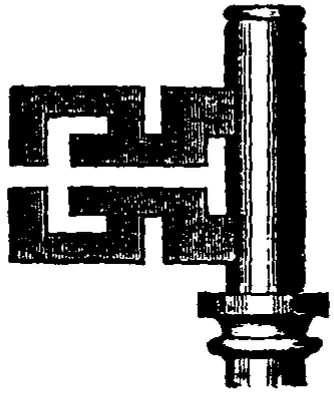

Figure 88 Room-door Key to a lock with bridge ward, etc.

Such is, in some measure, the case in the key from which figure 88 is drawn; although, as it is the key of a tumbler lock, both halves are brought into use at once, whatever may be the direction in which the key is applied, with this difference: that when the key is applied from the outer side of the door, the part marked ***a*** moves the tumbler and ***b*** the bolt, while when the key is put into the lock from the inner side ***a*** moves the bolt and ***b*** the tumbler.

The other illustrations of warded keys are intended to explain the theory of warded master keys, which was early understood by the ingenious locksmiths of Wolverhampton. In figure 87, the wards of the keys Nos.9, 10, and 11 are so far different from each other that neither of those three keys would open the lock designed for either of the other two, but a key formed like No.12 would readily open any of the locks of the other three, or any other of a more extensive series or suit of locks constructed on the same principle.

One defect of the principle of security by wards is that however complicated they may be, an ingenious picker will mostly be able to detect their form and position, by inserting a blank key with the bit covered with wax or tallow, so as to receive an **impression(468)** of the concealed obstructions in the lock.

It is well to observe that it is a very common practice to cut **more notches(469)** in the key than there are wards in the lock, so that the complex appearance of a key is no certain proof of the secure construction of the lock to which it belongs. Indeed some of the commonest locks are manufactured without any wards at all, although the keys are invariably made as if wards were employed.

A system prevails in the manufacture of warded locks of making

quantities in suits, i.e., making so many locks, say ten or twenty, each to differ, but with a master key to pass all of them, and also hundreds of locks for the same key to pass.

These orders are constantly repeated by the various ironmongers to the lock manufacturers or factors, so that in every town there are sure to be a considerable number of locks precisely the same in every respect, and which can be opened by each other's keys.

A set of twenty skeleton keys, similar to figure 89, would probably open nearly all the outer door locks in any city or town in the kingdom; and the keys of the patterns Nos.4, 12, 21, 22, 23, and 24, (figure 87) will open nearly three-fourths of all the common locks which are annually manufactured.

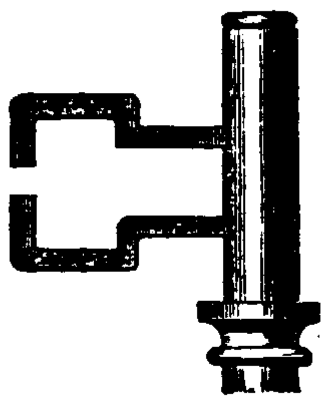

Figure 89. Skeleton Key

There is doubtless an advantage to ironmongers in supplying locks to their customers, which, when the key is lost, can so readily be opened by another key or one of the pick-locks (figure 87). Such a system should be at once abolished, as there can be no real security to those who use such locks whilst it exists.

We cannot better illustrate the consequences of this custom, than by stating a circumstance that occurred some short time ago in London.

A gentleman occupying one of a row of houses, the fronts and internal arrangements of which were exactly the same, went home late one evening, and by accident went to the door of the wrong house; but having inserted his key in the lock and let himself in, the mistake was not discovered until he found himself in his neighbor’s chamber.

Tens of thousands of warded locks are made annually, the whole of which are only duplicates of those which have been made every year for the last century.

We frequently expend from two to three pounds in the purchase of a brace of pistols, or a gun, as a means of preservation from the attack of burglars, when for less than half that amount spent in secure outer fastenings, the citadel might be kept perfectly safe against unwelcome intruders.

Locks, like all other articles in such common use, are considered of little importance by the majority of those who use them, and when from time immemorial we have been in the habit of purchasing a large lock for two or three shillings, it undoubtedly requires a certain amount of courage to give fifteen to thirty shillings for a lock similar in size. Unfortunately, size with many buyers is the only standard of comparison of the merits of various locks.

M.de Reaumur says, “There are no machines more common than locks: they are sufficiently complex to merit the name of machine; but I know of no others, the structure of which is so little understood by those who use them. It is rare to find anyone who knows wherein the goodness of a lock consists, or the **degree of security(470)** that he can attach to it. The outside of a lock is usually all that attracts attention. Doubtless the important uses to which locks are applied would excite curiosity respecting their structure, if curiosity were always excited for worthy objects."

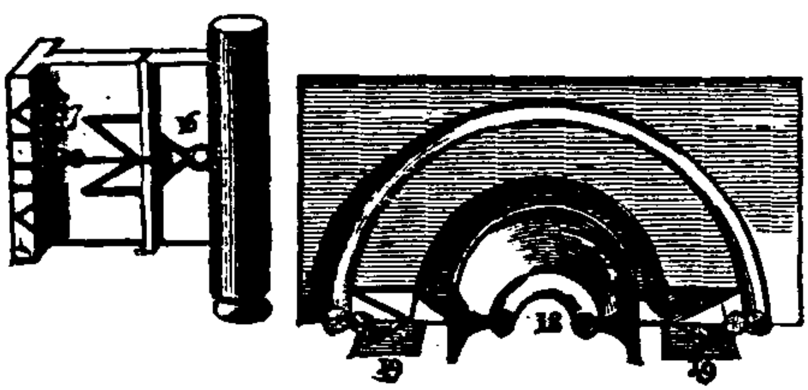

Figure 90. Wards of an Old French Lock

Some of the warded locks of the last century are curious. While the idea prevailed that a complicated ward gave security, there was room for the exercise of ingenuity in varying the shape of

the wards.

Figure 90 is copied from the great French work. It represents the cuts in the key, and also (seen from one perspective) the complicated forms of the pieces of metal which constitute the wards corresponding with those cuts.

The aperture in the key at 16 fits upon the metal surrounding the keyhole at 18; and the M-shaped cuts at 17 fit in like manner upon the similarly-shaped pieces at 19.

Another example of a similar kind is shown in figure 91, where an anchor appears to have been the favorite form. The anchor-cuts in the key are shown at 26; while in the wards the bottom of the anchor is near the keyhole at 28, and the top at 29.

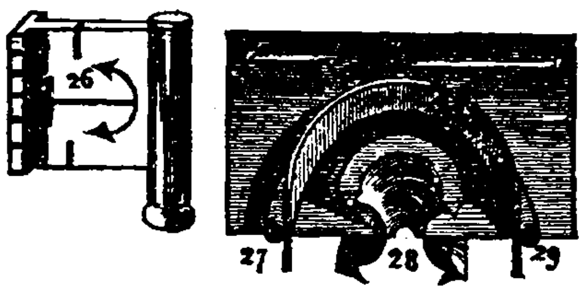

Figure 91. Wards of an Old French Lock

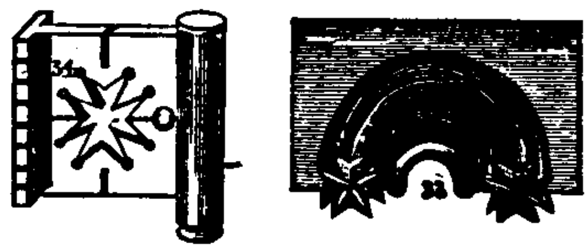

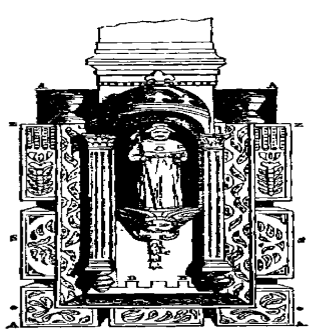

Figure 92. Wards of an Old French Lock

A similar illustration occurs in figure 92, where the star-like cuts at 34 on the key correspond with the star-like wards at 33.

From the fifteenth to the eighteenth centuries, locks were made in France, upon which a vast amount of **care and expense(471)** was bestowed. They were, in an especial degree, decorative appendages as well as fastenings.

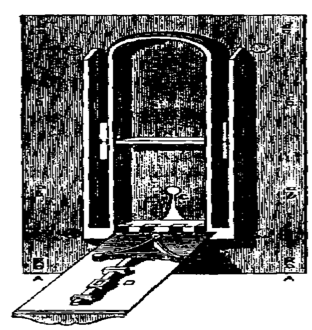

Figure 93. Exterior of an old Secret Lock

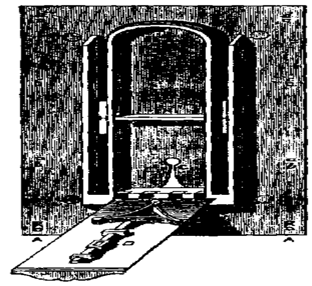

Figure 94. The same with a portion of the of the front let down, shewing the keyhole

chest-locks; they were fixed on the outside of the door or lid, so as to be fully visible. The key had a multitude of perforations which bore no particular relation to the wards of the lock, but which were regarded as tests of the workman's skill. The honorary distinctions awarded to apprentices and aspirants in the art, depended very much on the number and fine execution of these perforated keys.

The locks, considered as fastenings, had slender merit; although usually throwing four bolts, they were not very secure. Figure 93 represents the exterior of a lock made about the year 1730, by Bridou, a celebrated Parisian locksmith.

It was a lock belonging to a coffer or strong chest; all the works being sunk below the level of a carved architectural molding or ornament. There is a secret opening near the part c, forming a portion of the ornamental design. It allows a bolt, shown at D, (figure 94) acted on by the spring E, to be touched by which a doorway opens upon the hinges at BB. AA are a sort of pilasters, which aid in forming a hole for the bolts.

The little ornament at c is drawn down by the hand, opening the secret door and revealing the keyhole G. SS, 00, ZZ, are ornaments fastened on at b, c, d, figure 94, by nuts and screws, intended to display the skill of the workman. The lock itself, access to the keyhole of which is obtained within the secret door, has nothing very remarkable about it.

Figure 95 represents a safe door lock-case with a box of wards as generally used for cast-iron and common wrought-iron safes and chests. It is the kind of lock that enables any ordinary thief so readily to open such depositories, not only by a skeleton key, or other pick-lock, but by gunpowder also. The outer circle of metal which encloses the wards of the lock will of itself hold several ounces of gunpowder, and the lock-case or chamber a will hold some pounds.

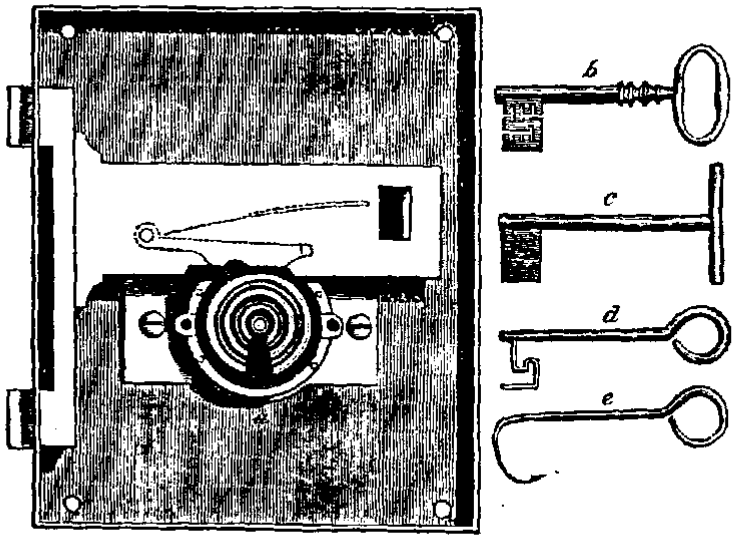

Figure 95 Lock-case, with Box of Wards

The comparative security or chances of opening the warded locks were supposed to depend upon the complexity or simplicity of the form of key required. Consequently, great ingenuity was displayed in arranging and shaping the forms of the wards and the keys corresponding to them.

Such locks can never be secure, because the underlying principle is flawed. The **number of combinations(472)** the lock is capable of, is comparatively so small, so that even in an ordinary dwelling-house, when the key of any particular lock is lost, how often does another on the same ring supply its place equally well.

Although this is so, yet there is millions of pounds worth of convertible property constantly under the care of such a worthless guard. The cuts in the key give it such an appearance of security, that many believe the warded locks to be far more secure than the improved modern locks that have plainer keys.

This is not altogether to be wondered at, when all a purchaser sees of the fastenings of his safe, or other depository, is the **key(473).** The owners of safes, which are secured by such locks, only find out that they are valueless, when they have been robbed of the contents.

The mode of **picking(474)** these locks is as follows: A blank is first made like *c*, (figure 95) generally of tin, the bit of which is smeared over with a composition of bees' wax, oil, and

powdered charcoal.

It is then inserted in the keyhole, and pressed against the wards, and an impression of their shape and position is thereby taken. A skeleton key, or pick-lock *d*, is next formed out of the marked blank, and for every purpose of locking and unlocking, it answers quite as well as the proper key *b*, as it is only necessary to preserve the *end* of the key bit, which comes in contact with, and moves the bolt.

Most of these locks can be picked by an instrument *e*, which is made of steel, and may very properly be called the burglars' skewer. It is passed outside of the outer ward, or wheel, and by a strong grip, will at the same time lift the tumbler and move the bolt. By inclining the door towards the hinges, it is only necessary to lift the tumbler with this instrument; when the bolts will fall down by their own weight and the door is thereby opened. By such assistance it unlocks itself.

Thousands of warded locks are annually made, in which the only security is a single tumbler, so that the only instrument requisite for locking and unlocking, is a skeleton key, like *e*, or just a blank key.

The multiple locks on the foreign coffers belong to this description of lock, and display considerable ingenuity in their construction. We have previously described the general construction of these coffers, and shall here confine our remarks to their locks.

The security consisted doubtless in the number of the bolts, but by far the principal security lay in the size of the key, and the great strength required withdrawing the bolts. In many of the foreign coffers, the lock is covered with a beautifully pierced and chased ornamented plate, as in figure 2, which partially hides the works of the lock.

Figure 96 represents the “strong German coffer” described by Reauniur, who says, ‘Not, withstanding the large size of these locks, and all the apparatus with which they are provided, they correspond but ill with the solidity of the rest of the coffer. If we have given a representation of one, it is chiefly to show how little confidence one could have in such a lock, and what are its defects, in order that we may avoid them."

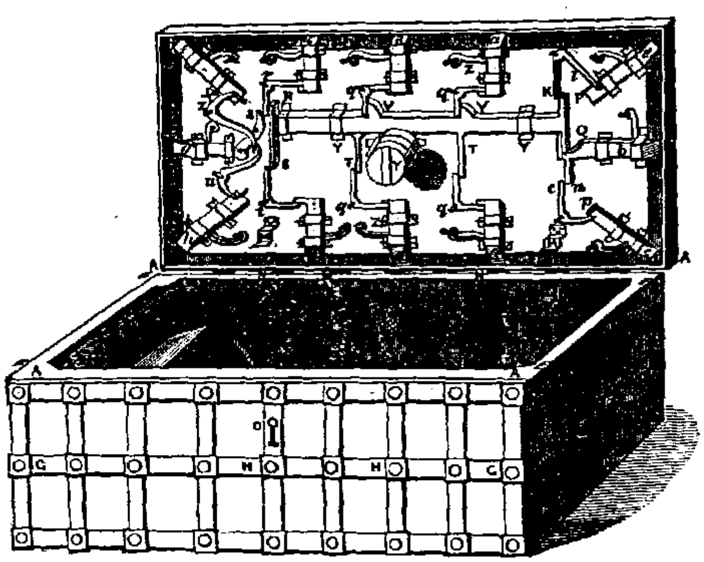

Figure 96. Strong German Coffer

It may be observed that there are, in figure 96, twelve bolts, each of which is connected by a powerful spring, z, to a long bar or lever, which may be properly designated the main bolt. H, f, d, c are the four corner bolts; a d e are the three each at the back and front, and b g one at each end.

There are no staples or bolt-holes in the top of the coffer to receive the bolts, but a projecting inner rim round the top at A A, under which all the bolts shoot. The bolts are usually beveled, so that the coffer locks itself, by closing the lid with a little force.

The keyhole in the front of the chest at D is a **deception(475)** or mask; the real keyhole being in the middle of the lid, concealed by a secret escutcheon, which is secured in its place by a spring. In unlocking, the key moves the main bolt, which simultaneously withdraws the other bolts P, Q, R, S, T, etc., and whilst the key is holding them back, the lid is lifted up and the key taken out. v v are studs which act upon two of the bolts. Y Y are staples confining the main bolt. k, l, c, p, x are small levers which transmit the action to the comer bolts; q, r, s, t, u, are other small levers which render a similar service to the front, back, and end bolts;

L L within the chest are the studs by which the “dogs " m m on the lid assist in securing the back of the chest when locked. As previously remarked, the multiple lock is only the rude lock multiplied by the number of its bolts, which if comprising twenty

can as easily be picked as if it had only one. It is not so much a lock as a series of spring latches, and any instrument sufficiently strong to move the main bolt will easily unlock it.

Besides the key, there is usually an instrument like a turn-screw, which is used for releasing the escutcheon and to put through the bow of the key for a lever. Without the aid of such a lever, the bolts cannot be withdrawn.

These coffers are by no means scarce, as we have frequently met with specimens in various parts of the kingdom, as well as in London, and there are several smaller ones at Marlborough House, in all of which the construction of the multiple lock is the same. There are different opinions as to the country in which these coffers were manufactured; some consider they are from Spain, while others pronounce them to be of German manufacture.

The keys to these multiple locks form a strong contrast to the keys of the locks belonging to similar depositories of modern date. The enormous size of the coffer keys precluded their being carried about the person, except when attached to the girdle. Many of them measure from ten to twelve inches in length.

As before stated, some contrivance is necessary to keep the bolt steadily in the position in which it is left by the key. In locks which depend upon wards for their security, this is usually effected by means of a spring, as illustrated by figure 97, which represents the interior of a small cupboard lock, with the bolt, ab, locked out, and capable of being moved backwards by the action of the key at c in a curved hollow, formed in the lower edge of the bolt.

This hollow or curve is called the "talon." The top of the bolt carries a long elastic piece, formed by nearly separating a stout lamina of metal from the body of the bolt, or as is more frequently done, by fastening a piece of tempered steel into a slot made in the top of the bolt, as shown in figure 97, and giving it an inclination to diverge from the bolt at the end b; and the lower edge of the bolt, behind the curved part acted upon by the key, is indented with two deep notches, *b* and *d*, with a smooth convexity between them.

The opening in the back rim, through which the end *b* of the bolt passes, is so small as to compress the spring with considerable force. If, therefore, the key be so applied as to shoot the bolt forward, the reaction of the spring will cause the notch *b* to

hold firmly on the edge of the rim, from which it cannot be disengaged without raising the bolt, and compressing the spring. This allows the convexity between *b* and *d* to pass over the edge of the rim, after which the notch *d* will hold on the rim in like manner.

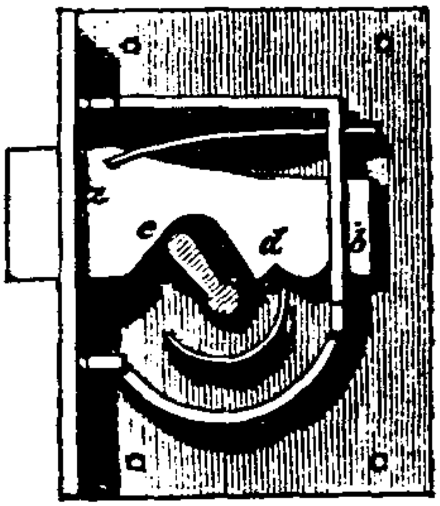

Figure 97. Back-spring Lock

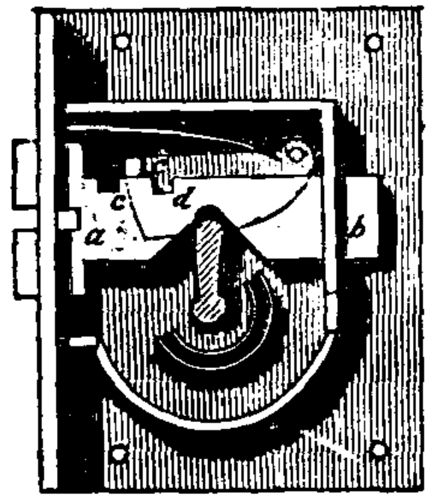

Figure 98. Common Tumbler Lock

The necessary raising of the bolt and compression of the spring is properly effected by the action of the key, but as it may be effected by pressure upon the end of the bolt, the security of locks in which such an arrangement is adopted, which are called back-spring locks, is inferior to that of tumbler locks. This is because of the means of retaining the bolt in its position, as well as from the defects already explained as incident to the use of wards.

We pass naturally from the consideration of the back-spring, as an essential feature in a lock protected by wards alone, to the explanation of one of the simplest modes of applying the second principle of security, that which consists in the use of moveable impediments to the motion of the bolt, and which may be applied, as an additional security, to locks in which the most ingenious arrangements of wards is employed to prevent the access of a false key to the bolt.

Figure 98 represents a lock similar to figure 97, provided with a *common* tumbler. In this figure the bolt *ab,* though shot backwards and forwards in the same manner as that of figure 97, has no spring or notches to catch on the back rim of the lock to

hold it in any required position. It is provided with two notches in its upper edge, at *c* and *d*.

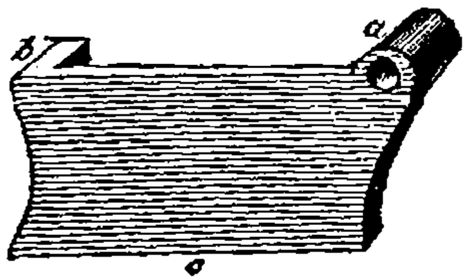

Figure 99 Common Tumbler

Behind the bolt is a piece of metal called the tumbler (figure 99) pivoted to the plate of the lock at F, (figure 98) and continually forced downwards by a spring which presses upon its upper edge. The upper part of the tumbler, which is visible above the bolt, is distinguished in figure 98 by being covered with a light tint, while the shape of the lower part, which is concealed by the bolt, is indicated by dotted lines.

At the angle e (figure 98) the tumbler carries a projecting stud b, (figure 99) which, when the bolt is fully shot, falls into the notch d. This holds it firmly, until, by the application of the key, (the bit of which reaches the lower edge of the tumbler), the tumbler is lifted up to the position shown in figure 98. In this manner, the bolt is released so that the further turning of the key shoots it back when the stud of the tumbler falls into the notch c and again secures the bolt.

It is obvious that so long as the tumbler remains in its proper notch, the bolt cannot be moved backwards or forwards by any pressure upon its ends; and also that the lock cannot be opened by any false key unless its bit be so formed as to reach the tumbler as well as the bolt.

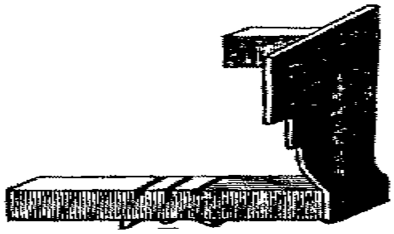
To render this more difficult, the tumbler is often made to fall a little lower than the bolt, so as to be acted upon by a step formed on the bit of the key. Further complication and security may be obtained by the use of two or more tumblers, which may be acted upon by different steps on the key.

The great exactness requisite in the length of the bit forms a strong recommendation of even the commonest tumbler locks; for if the bit be ever so little too short it will not lift the tumbler out of its notch, while if it be but a very little too long, it

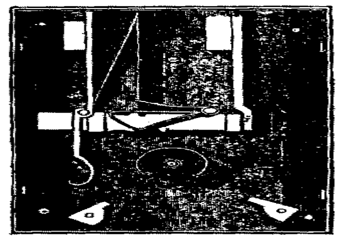
will not enter the curved portion of the bolt.

The common tumbler lock, like the back-spring lock, is easily picked, as it is only necessary to lift the tumbler sufficiently high when the bolt is easily set free. An expert mechanic, therefore, finds little difficulty in throwing out the tumbler, and at the same time moving the bolt.

There is nothing on record relative to the date when the tumbler was first invented, neither can we ascertain in what country it was first used. “The invention has been claimed by or for persons subsequently to the year 1767, when the celebrated French treatise (*Art du serrurier*) already referred to was published; and yet this treatise contains numerous examples of simple tumbler locks of ingenious construction, as will presently be shown.”



That tumblers were in use in the sixteenth century, in England, is evident from the specimens of that period now in existence. The Elizabethan lock, shown in figure 76, contains a well-constructed tumbler, and also a revolving barrel, the latter a contrivance which is to be found in many of the French locks of a later period. The revolving barrel in combination with the curtain has only recently been adopted.



“The great French treatise proves that the locksmiths of France were familiar with tumbler locks a century ago. The plates of that work represent the details of numerous locks, on the upper edge of the bolts of which were notches called *encoches, as* at *o k,* figure 100."

"Into these notches sank a small iron stud or stump called the arret du pene, or bolt stop, shown in figure 101. It was attached to the upper portion of the *guchette* or tumbler, which for the sake of economy of metal is made in the form of a triangular spring in front of the bolt ki."

"Not until the key, by its circular action, had raised this stud out of one or other of the notches, could the bolt move to the right or left. The stud was generally fixed to a spring which forced it down again into the notch as soon as the action

which forced it down again into the notch as soon as the action of the key had ceased."

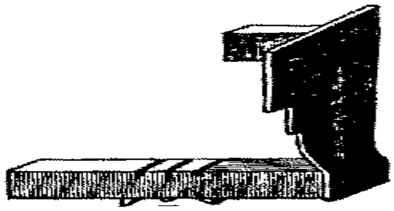


Figure 100. Bolt of old French lock

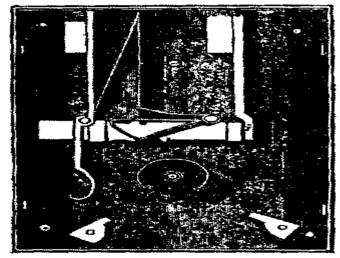

Figure 101. Old French Lock

Sometimes, however, the stud was fixed to the bolt, and the notches were in a separate tumbler or *guchette* (see E E, figure 103). In other instances again, the stump was fixed to the case of the lock and caught into notches in the bolt.

It will be seen, when we come to the treatment of tumbler locks of later date, that there was much in these early locks to point out the way. Figure 101, copied from the French work, represents a lock of the box or casket kind. Two staples, fixed into the cover, fall into two cavities or receptacles at *c d;* and a short bolt in each receptacle catches into each staple, one near *g*, and one near *h*. The small bolt is attached to the upper extremity of the lever *q r s, (*figure 101,) and shown separately in figure 102. By the pressure of a spring *a* (figure 101) upon this lever, the bolt *q* is kept locked in the staple.

Figure 102. Small b old French loc

The vertical portion of this spring presses at its lower end on another spring *P* (figure 102) of singular curvature; and attached to the horizontal part of this second spring is the stud, which falls into a notch in the top of the bolt.

The action of these parts, then, is as follows: when the key is placed upon the key-pin at *z*, and turned round in the direction in which the hands of a watch move, the bit presses against the tail *s* of the lever, moves it upon its center *z* (Figure 101*), v* (figure 102) to the left, and consequently moves the upper part *q* to the right, drawing it out of the receptacle and liberating the staple within *c*.

Thus it will be seen that the lever *q r s,* held in one position by the spring *a*, forms in itself a simple kind of spring

catch-lock, and was, in fact, formerly used as such, without any other appendage except the staple in the lever, into which the catch *q* fitted on shutting down the lid.

So also we may regard the other portion, figure 100, or *k, i, p, h,* (figure 101) as forming a separate lock. The key, after having passed *s*, comes in contact with the triangular spring, which it raises thereby, lifting the stud out of the bolt, and exerting pressure against the barbs of the bolt *n.* Figure 100 shoots the bolt *k,* and also the short bolt *l*, which passes through the staple in the cavity *d,* (figure 101).

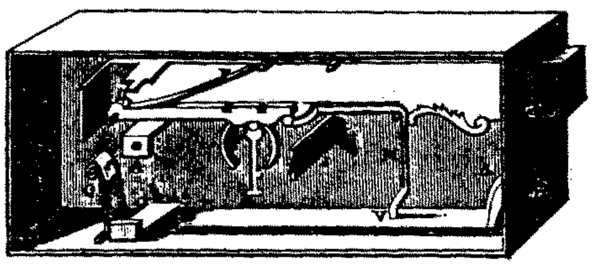

Figure 103. Details of Old French Lock

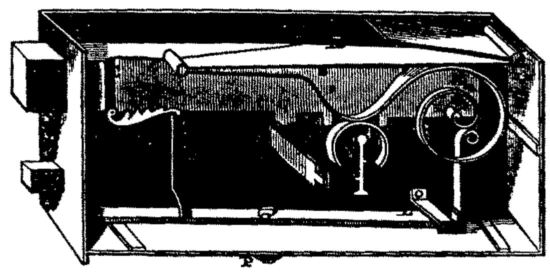

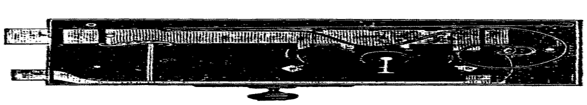

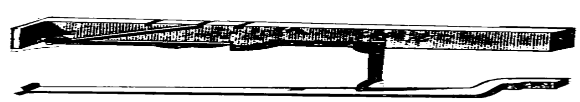

Figure 104. Another view of the same

The lock represented in the four following figures is also from M. de Reaumur's chapter on locks in the work referred to. In this lock the tumbler principle is carried out in a very elaborate manner, for not only is the stump or stud H (figure 105) attached to a very strong spring (best shown at H, figure 104) which holds it with considerable force in one of the three notches of the principal bolt *R S* (figure 106); but there is also a second set of notches *e e* in the *guchette g o* I (figure 103), and a pin attached to one of the plates of the lock fits into one of these notches.

This prevents the bolt from being moved until the *gauchette* is lowered by the revolution of the key; so that in attempting to pick this lock, not only must the spring *H* be raised so as to release the stud from the notches of the great bolt, but the *gauchette* must be lowered to disengage the fixed pin from the notches.

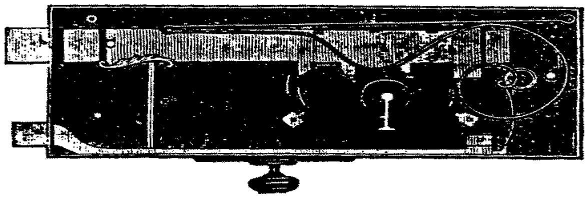

Figure 105. Another view of the same

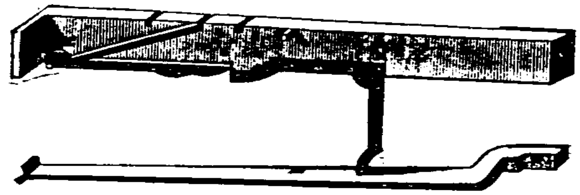

Figure 106. The two bolts detached

There is yet a third source of security. Attached to the large bolt are short projecting pins *F* (figure 103) against which an arm or detent, *G F*, of the *gauchette* projects, thus preventing the bolt from being shot back by any pressure applied to its extremity *S.*

There are a few details relating to this remarkable lock, which may as well be introduced here in order to complete the description. The principal bolt can be shot twice, or be *double-locked*; hence it is furnished with three barbs for the key to act against, and with three notches for the spring-stud.

The lower bolt *I k* can be shot by the horizontal pressure of the button *P* (figures 104-105), which is situated on the inner side of the door to which this lock is attached, so that a person inside the room can secure the door against anyone on the outside who is not furnished with the proper key, for it must be remarked that the small bolt as well as the large one is acted on by the key.

Now supposing the small bolt to be shot or locked, it is kept so by the pressure of the coiled spring *Q* (figures 103-104). But this small bolt is connected with the large one by means of the bent lever *o n m* (figures 103-106) which turns on a pin *N* attached to the main bolt.

Now, when both bolts are either fully shot or unshot, the arm *O N* lies flat against and parallel with the main bolt. When the large bolt is unshot and the small one not moved, the arms *O N, N M,* fall into an inclined position, and the arm *O N* passing a little below the main bolt comes within the range of the web of the key, which in its revolution causes the bent lever to move upon its center *N*, thereby restoring *0 N* to its horizontal position, and at the same time causing the arm *N M* to move from right to left, or in the direction for unshooting the small bolt. The end of this arm thus catches into a mortise *v* (figures 103-106) in the small bolt, and immediately unlocks it.

We have now described the whole of the locks known in England previous to the reign of James the First, and we shall here insert a correct list of all the patents granted for "locks and latches" since that period, to April 1851, and describe those which contain any peculiarity of construction, or any contrivance of sufficient merit to interest our readers.

List of Patents granted for Locks and Latches, from the time of James the First, until April 4, 1851, compiled from an "Alphabetical Index of Patentees and Applicants for Patents of Invention," published by order of the Honorable Commissioners of Patents, under the Act of 15 and 16 Vict., cap. 80, sec. 32.

***Those marked thus are not for improvements in the construction of locks or latches, but for contrivances in some way connected with them, and for fastenings for doors, windows, shutters, etc.**

The following lock was invented previous to May 1851, though not patented until 1852. It was exhibited at the Great Exhibition of 1851, and consequently it will be described in this chapter.

Besides those named in the preceding list, there are many other locks which are *called* "patent" whereas no patent has ever been taken out for any of them, and we understand it as a very common circumstance for applications to be made at the office of the Commissioners of Patents for information relative to "patents" which never existed.

The following list comprises all the other locks we have heard of, the improvements in which were not *patented*. Many of these will be described as we proceed.

Locks that have not been Patented by Claim to have received a Patent

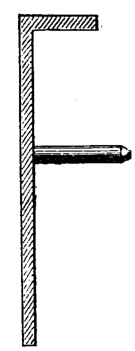
Eagle's	**Stanley's**
Edwardes'	**Steele's**
Foster's	**Strong's**
Friend's	**Stuart's**

Having arrived at that portion of our work when plainness of diction and perspicuity of description becomes absolutely necessary for a correct appreciation of the various patented and other locks, and the differences in their construction and their comparative merits, we think it will conduce to an easier understanding of the subject, to first explain and illustrate the several principal parts of which most locks are composed.

Definitions and Component Identification

The "back-plate" is that into which the "drill-pin" which receives the key, and other portions of the works of the lock are riveted.

The "cap" is that part which covers the internal mechanism of the lock. It is usually fastened to the back-plate by two screws. The cap used to be made of iron, hammered and bent to the required size, shape, and riveted to the back-plate. The caps of the very commonest locks of the present day are made and fitted in the latter way.



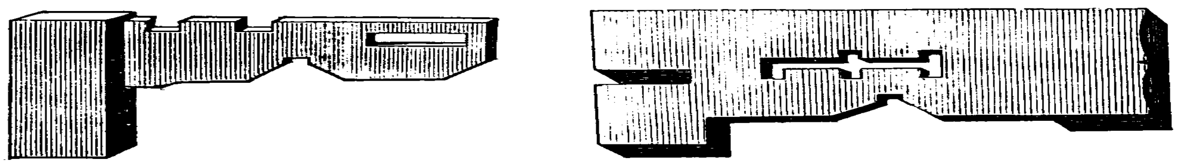


Figure 107. Bac

The **talon** of the bolt, **b**, (figure 109), is that part by which it is moved backwards or forwards by the end of the key-bit being forced against it.

A *common* tumbler bolt has the "racks" or "notches" in its top

A *common* tumbler bolt has the “racks” or “notches” in its top edge, as shown in figure 108.

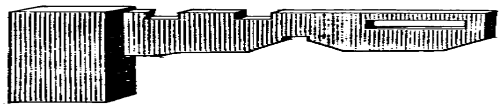

Figure 108. Common Tumbler Bolt

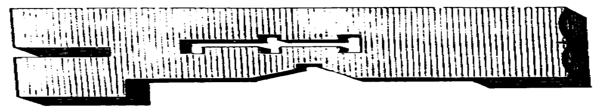

Figure 109. Bolt to a Barron's Lock. a, The gating. b, The talon

The bolt of a Barron's lock has the "gating" in the position shown in figure 109.

The term "double-acting" means that the slot in the bolt or lever has "notches" or "racks" at the top and bottom of each opening, as shown in figures 109 and 111.

The "gating" in the **bolt** is the slot or narrow passage through which the stud or stump of the tumbler moves. The "gating" in the **levers** is the slot or narrow passage through which the stump of the bolt moves. The bolt with the gating belongs particularly to all the locks known as Barron's, and the bolt with the stump to those known as Chubb's or other lever locks.

The "stump" of the bolt is that stud which projects at right angles from the face of the bolt, and which passes in and out of the "slots" through the gating in the levers, or combinations, or other moveable obstructions contained in the lock.

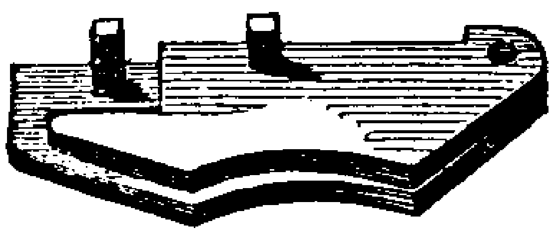

Figure 110. Pair of Barron's Tumblers. A, The Front Tumbler. B, The back Tumbler.

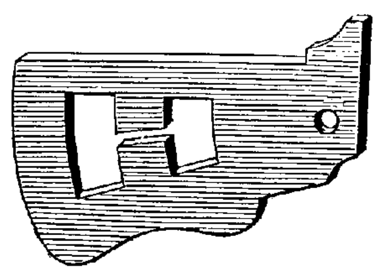

Figure 111. A lever as used for most locks of that kind

Figure 110 represents a pair of Barron's tumblers, the stumps of which move in and out of the slots through the gating in the bolt *a* (figure 109)

All the writers on locks up to the present time have used the terms tumbler and lever synonymously, but as there is a difference between the two, as shown in figures 110-111, we shall, throughout the work, observe the distinction. This distinction is strictly attended to in every workshop in the

district, for as a master locksmith remarked to us when discussing this pint, if he were to send one of his men for a tumbler, he would certainly bring him a *Barron's tumbler;* and if he asked him for a lever, he would give him one *similar to Chubb's.*

We have often heard the word tumbler used to express the different locks having moveable impediments to the passage of the bolt, and in this sense only is it admissible. Unless the distinction is strictly observed between the tumbler and the lever, confusion of ideas must be the result.

BLACK'S LOCK, Patent dated May 27, 1774.

The first patent granted for "locks and latches" was to George Black, May 27, 1774, for "a latch or lock so made as to raise the door over the carpet, and so made as to admit air into the room without opening the door."

Although there is nothing in the construction of Black's lock to add to the security of those which were then in use, yet as it is the first patent in connection with this subject, and as a curiosity, we should have printed the specification at length could we have procured a copy of it in time.

It has been thought by many that Black invented the "double-acting " tumbler, which, they say, Barron improved and patented in 1778, but there is nothing, whatever to support such a supposition.

BARRON's LOCK, Patent dated October 31, 1778.

As shown in the list of patents, it was in the year 1778 that the first great improvement in the art of making locks secure, took place. Mr. Barron, who had directed his attention to what is called the "tumbler " principle, added it to the warded lock.

In his specification, he claims "the gating or racking to allow a stump on the tumbler to pass through the bolt, or an opening in the tumbler to allow a stump on the bolt to pass through." This clearly proves that the invention of the modern, "lever," as well as double-acting tumbler," belongs to Barron.

Besides the above, he employed two or more tumblers, of the construction shown in figure 110, which, although similar to the *common* tumbler before described, are so arranged that they must

be operated upon at different times or altogether, and be moved so as to take the “stumps” completely out of their notches, and release the bolt, so that it can be moved backwards or forwards by the step of the key which acts upon it.

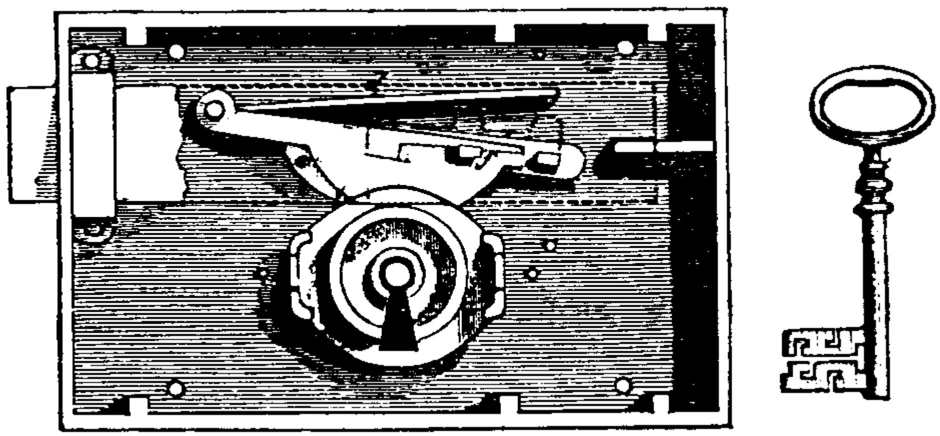

Figure 112. Barron’s Lock

Figure 112 represents Barron’s lock with wards and tumblers: *a* is the bolt; *b* and *c* are the two tumblers which are kept in their position by the spring *d*. The studs or stumps, *e f,* which project from the tumblers, retain the bolt in its locked position.

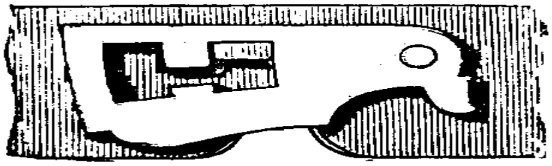
It is only with its own key *g*, which is cut in “steps" of different lengths to correspond with the varying lifts of the tumblers, that the latter can be raised to the exact height to bring the studs or stumps into a line with the slot in the bolt through which they pass, and thus allow the top step of the key to act on the talon *h*, and unlock it.

In the common tumbler locks, as stated before, it was only necessary to raise the tumbler sufficiently high to open the lock, it could not be raised too high. But in Barron's, there is a limit, for if the tumbler be raised either too low or too high, they either remain in the lower notches or get into the upper notches, and in either case prevent the moving of the bolt.

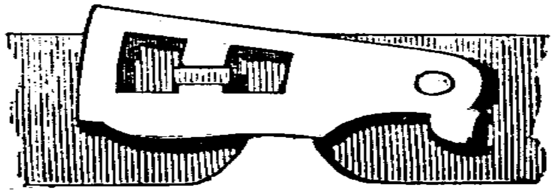
The tumblers, whether two or more, must be lifted exactly to the same height, at precisely the same time, and in a line with the slot in the bolt. The steps of the key are made to fit the inequalities in the width of the tumblers, so that all shall be raised to the required position at the same instant. Though the

upper and lower notches are applicable to a single tumbler, yet Barron, by using two, considerably increased the amount of security in his locks.

This lock, therefore, contains two important improvements on the common tumbler lock, viz., the double action of the tumblers in the bolt, and using two instead of one tumbler. Although this lock is constructed on precisely the same principle as the Egyptian, it is far superior, as the over-lift of the tumblers is a most important improvement and adds considerably to the security of the lock.



In the simple form of the tumbler represented in figure 99, there is the disadvantage, that, while it effectively prevents the removal of the bolt unless the tumbler be raised high enough, it presents no obstacle to its removal when, by the use of a false key, the tumbler is thrown up beyond the proper degree.



This defect is remedied in Barron's lock and in many more recent contrivances which are based upon it, by the use of from four to twelve *levers,* each of which requires to be raised to a different degree, and any one of which, if lifted too high, will form as effectual a barrier to the motion of the bolt as if it were not lifted at all.

To illustrate this, let *a* (figure 113) represent a lever pivoted at *b*, pressed downwards by the action of a spring, (not shown), at *c*. Underneath, or behind the lever, lies the bolt, a part of which only is shown, where it is distinguished by a dark tint, and at *d*, an opening, the gating and racking, somewhat resembling the letter H, in shape is cut through the lever, to allow a prominent square pin or stud, the stump, which is attached to the bolt, and is shown in the cut by a light tint, to pass through it.

It is obvious that the bolt, secured by such a lever, can only be shot when the lever is raised precisely to such a degree as to bring the horizontal portion of the H-shaped aperture opposite to the stud, so that the stud, which fits it accurately, may slip through it. Figure 114 shows the lever raised to this position, and the bolt half shot. When fully shot, the lever again falls; the stud is secured in that division or notch of the **H-shaped(476)** aperture which lies nearest the end of the lever.

H-shaped(476) aperture which lies nearest the end of the lever.

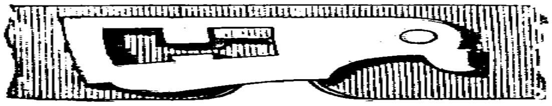


Figure 113. A Lever.

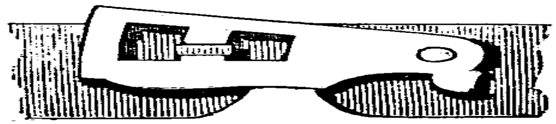

Figure 114. A Lever

An equal security is afforded against any attempt to return it to its first position by any key that does not lift it precisely to the proper height. Many such levers may be placed in one lock, the whole being mounted upon one pivot; and if the horizontal connection portion of the H-shaped aperture be placed at a different elevation in each, each will require to be raised to a different degree to allow the stump of the bolt to pass.

These different degrees of motion are provided for by variations in the curved portion of the lower edge or bellies of the levers, *e*, (figures 111-113) against which the bit of the key acts, and by dividing the end of the bit into a series of steps and notches, each acting upon a single lever. Figure 115 represents the bit of such a key adapted for a lock with either three tumblers or three levers. As may be seen from the cut, the lock to which this key is adapted is guarded by two wards of different forms, and the end of the bit is divided into four portions, of various degrees of projection, of which that marked *a* is employed for moving the bolt, while *b c* and *d* act upon the three tumblers or levers.

Figure 115. Barron's Key

In the event of such a key being lost to a lock with levers, or it being suspected that an impression of it had fallen into wrong hands, the levers of the lock might be taken out and returned on to their common axis in a new order, so as to require a key in which the members *b c* and *d* would stand in a different relation to each other, by which means the old key would be rendered utterly useless.

Barron’s Lock, when well made with three to six tumblers, and a well-constructed series of wards, is extremely difficult to **pick(477)**; for the wards, as previously shown, though useless as preventives to the operation of lifting up a single common tumbler, greatly impede so delicate a proceeding as the elevation of three or more to the precise height required for the passage of the stumps through the grating in the bolt.

A strong recommendation in its favor is its simplicity, and the strength of the various “limbs” which form the internal mechanism. There is also nothing in the construction of a Barron’s lock to render it very liable to get out of order.

The only successful method of picking the tumbler and lever locks is by applying pressure to the bolt through the Keyhole. We shall defer saying more relative thereto, until we discuss this part of the subject in the chapters on the Lock Controversy.

PRICE’S LOCK, invented about 1778.

About the year 1778 a lock was invented by Price, and was the first lock ever constructed with *four double-acting levers.* This lock bears a very close resemblance to those of more recent introduction. We have been furnished with a sketch of one of these locks, which was until lately in the possession of Mr. Aubin, of Wolverhampton, and which has been traced back to the above period.

The peculiarity of this lock was that it locked without the key by pressing a stud or knob, which released a common tumbler in the main bolt; the four levers had plain gatings. The bolt was driven forward, or locked out, by a powerful spring and “follow” resting against the bolt-head. To unlock it, the key was used in the ordinary way.

It may be well to remark here that all the modern spring or self-acting locks are constructed precisely on the same principle as that exhibited in this lock, except, that in the modern locks, the driving spring is placed against the bolt tail instead of the bolt head.

BRAMAH'S LOCK

No lock has been more generally used, the mechanism of which is less understood, than that produced by Bramah. It has continued

to have a most extensive sale from the period of its invention to the present time, and thus we must beg to be excused for giving at such length the following description and particulars relating thereto.

However great the number of new locks which may be introduced, none will interfere much with the almost universal employment of the Bramah lock, from the circumstance of its construction being so peculiarly adapted for all cabinet purpose, and the key of it being so conveniently small.

The majority of locks that are now or ever will be in use, are not required to be secure against the accomplished scientific thief, but only against the prying curiosity of children, servants, and employees. They must protect against petty fraud, and the designs of ordinary thieves; therefore, such locks as Bramah's or Barron's, well made, and there are now a great variety, will always command an extensive sale.

When locks are required to secure property of considerable value, as in banks, the fastenings to the depository should be as perfect and inviolable as possible, as the anticipated booty being so valuable tend to stimulates the ingenuity and enterprise of the highest class of burglars in devising complete and effective measures to accomplish the robbery.

A lock possessing perfect security with simplicity of construction, and which could be sold at a moderate price, is the article which all inventors, since the time of Barron, have been trying to fabricate. Almost every patentee, in his specification, states that he has accomplished this great and important desideratum.

It will be seen, as we proceed, that nearly every inventor, instead of simplifying that which had gone before, has complicated the construction without giving additional security. In the language of the workshop, he has added more "limbs" to the machine without increasing its security or utility, and it will most likely surprise many of our readers to find in the great number of locks that have been introduced, how few there are that can be called original, and how many there are that are "new" only in respect to the altered form or position of the several parts or "limbs" they contain.

We shall not forget the motto "Honour to whom honour is due," and it will be our object to point out to the general reader those

locks in which this copying or repetition exists. It is a fact which will be corroborated by a little inquiry and observation, that in the majority of inventions the so-called improvements are only complications.

The object of all improvements should be to simplify that which has preceded it; in other words, to construct a machine, say a lock, to be composed of only five pieces, which shall offer all the security, strength, and durability of others which comprise ten pieces.

Man's inventive powers seem to be like a lawyer's in a bad cause where there is plenty of money; the object being to complicate rather than simplify it. It would appear that our lawmakers also frequently act upon the same principle.

How different are all the contrivances of Nature, how beautifully simple are all the constructions of her machines. We do not see in her "handiwork" two "limbs" performing that which is better effected by one; and it is a fact that wherever an inventor has taken Nature for his guide, he has triumphantly succeeded in his design, as for instance, the "toggle," or knee-joint, etc.

Although Bramah's lock is constructed on the principle of the Egyptian, it will be seen that the mode of application is, however, very different. It is a compound of both end way pushing and revolving motion, which is also different from the simple rotary movement of Barron's lock.

We here insert, at length, the specification of the patent, published in the *Repertory of Arts*, for 1796.

BRAMAH'S PATENT SPECIFICATIONS, dated April 3rd, 1784

The principle of all locks hitherto known, or in public use, is too well understood to require any particular description here; yet it may not be improper to observe on what ideas their security was always founded, and likewise how far such principle may tend to render them perfect or effectual; by which may be obtained some comparative information necessary to show or explain the advantages and superior utility of this my said invention. The means hitherto adopted for the security of all locks are the inserting or fixing, between the keyhole and the bolt, a greater or a less number of wheels or wards.

Wheels or wards may be crossed or interwoven, in such a manner as

to render the communication between the keyhole and the bolt as irregular and crooked as possible, in order to prevent the said bolt from being moved by any counterfeit application when the key is absent. The bit of which said key is so cut or shaped as to form a complete tally with the said wheels and wards, and is thereby capable of producing the required effect, when applied for the purpose of moving the bolt.

Now the insufficiency of this method of rendering locks a perfect security is as follows, viz., notwithstanding the said wheels and wards may be variously placed and disposed, yet they cannot by any means become sufficient to answer the intended purpose, owing to their being always left fixed in the lock.

Their form and disposition can be easily obtained by impression; so that notwithstanding they may prevent the use or effect of pick-locks, yet the making a perfect or skeleton key is always extremely practicable.

And further, the **variations(478)** capable of being made in the disposition of the said wheels or wards, and the form of the key's bit, are not sufficient to produce the required number of locks, without having great quantities exactly alike, and their keys capable of opening each other reciprocally; from which they become a very imperfect security, as any ill-disposed person may, by furnishing himself with a number of old keys, be enabled to open almost all the common locks in the Kingdom, with as little difficulty as if he had in his possession the key belonging to each lock.

To remedy these objections, by discovering some principle or method whereby the success of pick-locks, false-keys, and all other counterfeit means of opening locks may be infallibly prevented, and has been the ultimate design of my said invention.

Such may be effected in manner following, vis.; instead of introducing (for the security of the bolt and other moveable parts of the lock) a number of wards and wheels, I have found out and invented much more simple and effectual means of rendering the said bolt and other parts entirely immovable, without the absolute application of the real key.

By those said means, the effects of pick-locks, the practicability of obtaining the form of the key, and the having a number of the said keys alike, are entirely avoided by having a greater or less number of moveable parts, such as levers,

sliders, etc.

These are adapted and placed in the lock, so as to require each of them a separate and distinct change in their situation and position, before the bolt, and other parts of the lock on which its safety depends, can be set at liberty or moved.

These said levers, sliders, or other movables, by the assistance of an elastic, gravitating, or other power, have the property of maintaining, or restoring, their given position or situation, after it may have been destroyed by any forcible application for that purpose.

From this said property, the said levers, sliders, or other movables, are rendered capable of receiving (as it were) any impression or required change in their position or situation, correspondent to the cause which produces such said change, and are also thereby always restored to their former state, or resting situation, when the said cause is withdrawn.

So that the opening these, my said invented locks, is as difficult as it would be to determine what kind of impression had been made in any fluid, when the cause of such said impression was wholly unknown; or to determine the separate magnitudes of any given number of unequal substances, without being permitted to see them; or to counterfeit the tally of a banker’s cheque, without having either part in possession.

The form of these said levers, sliders, or other movables, and also the manner of fixing them in the lock, may be varied without end, without altering or losing any of the intended properties or advantages, as the principal merits and efficacy of my said invention in no way depends thereon.

Rather, it entirely depends upon the said levers, sliders, and other moveable parts being so fixed or disposed as to prevent the bolt, or other parts of the lock on which its safety depends, from being moved, without the said levers, sliders, or other movables first receiving each of them a separate and distinct change in their position or situation, by a key or other contrivance for that purpose.

Such must be pushed or pressed in a progressive direction, without revolution, against some part of each of the said levers, sliders, etc., that occasions them to change their positions, in manner exactly correspondent to the part of the key so applied.

And the said part, being formed with a number of irregular surfaces, equal to the number of levers, sliders, etc., against which it is pushed or pressed, causes them to move at different times, and to different distances from their original situation.

And the said key, by having a stop, or some mark whereby to limit or determine the length of its push against the said levers, sliders, etc., puts a period to each of their motions, notwithstanding they are at liberty to move farther, but are prevented by the resistance of a spring, gravity, or other poser, always endeavoring to restore them to their original situation.

So that the motion of each lever, etc., separately, depends on the height or depth of that surface of the key against which it falls. So that perfect tally is formed, similar to any impression made in a soft body by the forcible application of any harder one. Said hard body represents the essential part of the key, and may be of any determinate shape, formed by rule or by accident; and the moving the bolt or other parts of the lock whereby it may be opened, entirely depends on the positive motion of the said levers, sliders, etc., as any one of them would, by being pushed the least degree too much or too little, entirely prevent the bolt, etc., from being moved or set at liberty.

And, as the whole of the said levers, sliders, etc. are restored to their resting situation when the key is withdrawn, by the properties or powers above-mentioned, the said tally or impression is then totally destroyed, and consequently the opening of the lock is then left wholly dependent on chance, whilst the said key is absent, as there is no rule whatever, nor imagination founded on certainty, that may in the least degree tend to assist in discovering the required position or situation of each or any of the said levers, sliders, or other movables whereby the form of the key, or the part of the said key necessary to the opening of the lock, might be ascertained.

Now, admitting that no lock on this said principle can be picked, or the form of the key obtained, their farther security then depends on the number of different keys that may be made without having any two of them alike, which number I trust will appear indeterminate from the following demonstration.

Let us suppose the **number of levers(479)**, sliders, or other movables by which the lock is kept shut, to consist of twelve, all of which must receive a different and distinct change in their position or situation by the application of the key, and

each of them likewise capable of receiving more or less than its due, either of which would be sufficient to prevent the intended effect.

It remains, therefore, to estimate the number of differs which may thus be attempted, viz., let the denominations of those levers, etc., be represented by twelve arithmetical progressions, we find that the ultimate number of changes that may be made in their place or situation is 479,001,600, and by adding one more to that number of levers, etc., they would then be capable of receiving a number of changes equal to 6,227,020,800, and so on progressively, by the addition of others in like manner, to infinity.

From this it appears that one lock, consisting of thirteen of the said levers, sliders, or together moveable parts, may (by changing their places only, without any difference in motion or size) be made to require the said immense number of keys, by which said lock could only be opened under all its variations.

Wherefore it likewise appears that the said number of locks may be made, consisting of the same parts, without the smallest difference whatsoever, and, by varying the places of such said parts, would require each of them a separate key, and not one out of the whole number above-mentioned be capable of opening any lock, except that particular lock to which it belongs.

Now it must be observed, that the number of different locks, above stated, is produced by thirteen movables, (to wit,) levers, sliders, etc., which having all a distinct difference in their required motions, determines their denominations or names, without any relation being had to the separate value or positive motion of each, which said motion may be given at discretion, so that it plainly appears that the number producible from a like number of levers, etc., is far from terminating here, as their motions, and the difference in proportion one to another, may be varied without end, and are to be added to the former.

It is therefore very obvious from this demonstration, that a much less number of the said levers, sliders, or other movables, will be found sufficient to produce any required number of the said locks, without having any of their keys to pass each other. These said levers, sliders, or other movables above-mentioned, may be adapted and applied to all sorts of discretionary fastening whatever, such as bolts, bars, turnbuckles, etc. The figures or drawings hereunder written, or hereunto annexed,

together with the demonstration or description therewith given, will more fully show the true nature and intent of this my said invention.

“Before I refer to the drawings, I think it proper to observe, that the art of constructing locks wholly depends on some method or means, so adapted or contrived as to be rendered capable of admitting or preventing, at discretion, the motion of some fastening, such as bolt, bar, or other moveable part, which may be made of iron, brass, wood, or other materials sufficient for the purpose."

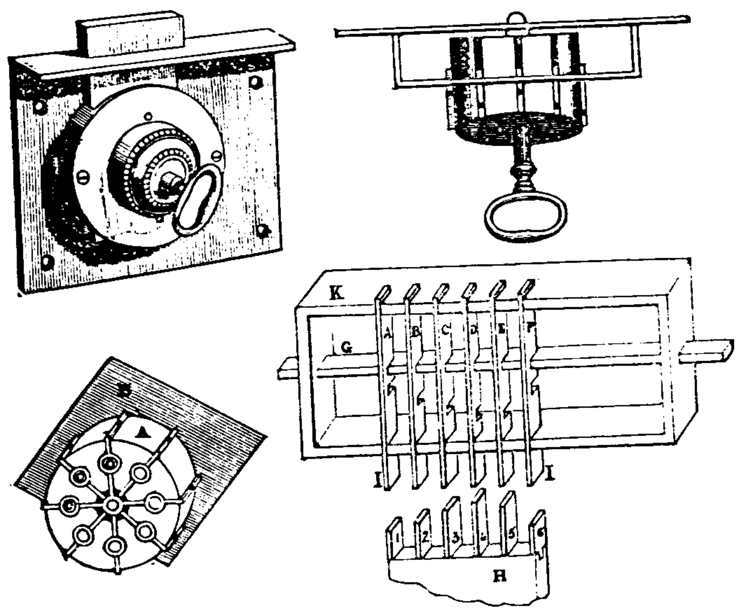

Figure 116. Bramah's Lock

Figure 116 represents the exterior of a Bramah until lock, with three diagrams to illustrate the principle of the sliders. *G* represents a sliding bar, or bolt, in the frame *X*, that contains within the cut in its edge six notches of any proper depth.

In these notches are placed six sliders, or small bars, *A B C D E F*, that are sunk into the bottom of each notch, so that the motion of the bar or bolt *G* is thereby totally prevented until these sliders are moved some way or other to give it liberty. This must be done from their ends at *I I*, as no other part of them is meant to be exposed for the purpose of moving them; which ends at *I I* always have an equal projection when the bar *G* is set fast.

Now we will suppose each of these sliders capable of being pushed upwards towards *A B*, etc. to any determined distance, and when each of them has exactly received its due motion, the bar *G* is set at liberty, so as to slide backwards and forwards as required.

Now in order to determine the separate and distinct motion that shall be given to each, we will suppose the part *H* to be made; which part serves to represent a key, and the ends *1 2 3 4 5 6* are cut of different lengths, either by rule, or by chance, so that when pushed against the ends of the sliders at *I I*, they will cause each of them to be moved up at different times, and to different distances from *I I*, in a form exactly correspondent to the ends of the part *H*.

When they have thus received their correspondent position, and their ends *I I* form a complete tally with the part *H*, by making a notch in each slider at *1 2 3*, etc., in a line with the bar *c*, the said bar will then have liberty to be moved backwards and forwards without obstruction; and, when brought into its original situation, and the part *H* withdrawn, the sliders *A B C*, etc. will then fall down into their notches, and fasten it as usual.

Their ends at *I I* will be restored perfectly even, as before, and not the least trace be left of the position required in them to set the bar *G* at liberty; it depends, therefore, entirely on chance when the part *H*, or key, is absent.

A is a frame or barrel that moves the bolt by its turning, in which barrel or frame are fixed eight, or any other given number of sliders. *B* is a thin plate fixed in the lock, through which the barrel or frame *A* passes, and is prevented from turning for the purpose of moving the bolt, by the projecting parts of the sliders that move in the fixed plate *B, un*til the notches in each of them are, by the application of the correspondent part of the key, pushed into contact, or in a line with the plate *A*.

At the end of each slider, in the cylindrical parts *c c c*, etc., is fixed a spiral spring, which always restores them after the key is withdrawn, similar to *A B C*, etc., by their own gravity."

c (figure 117) represents a spiral spring, which is lodged in each of the cells *c c c*, etc., in the barrel *A,* (figure 116). The other half of the barrel is filled with a slider that rests on the spring. *b* is the nib which is projected through the

interior groove into the space which forms the center or keyhole on which the key is pressed.

The office of these sliders exactly corresponds with that of the levers in the diagram *K*, (figure 116) "When lodged in their respective cells, they are upheld, like the levers, by the elastic power of the springs on which they rest, until a pressure superior to that power is applied; and are again restored to their stations by the reaction of the springs, when the weight which depressed them is withdrawn."

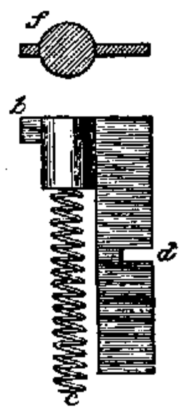

Figure 117. Bramah's first slider slider b, the nib. c, The spiral spring d, The notch. f, Top section.

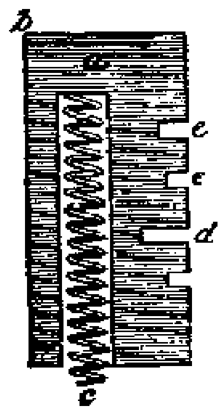

Figure 118. Bramah's with spiral spring, and False notches, as introduced in the year 1817. b, the point on which the key presses. C, The spiral spring. d, The principal notch or Main gating. eee, The False notches.

It will be well to notice particularly that Bramah's first locks were constructed with a spiral spring to each slider, as shown in figures 116-117, as we shall have to refer to this point hereafter. We have had lent to us for examination an example of these early locks, a large padlock. It is a beautiful piece of workmanship and proves the great mechanical skill of its inventor, and from its expensiveness must have been used to secure some depository of great importance.

It has eight sliders of the pattern figure 118, with a spiral spring, c, to each, and a slide escutcheon before the keyhole. At the top of the nozzle is a chamber for holding sealing wax to prevent the raising of the slide.

We have omitted several of the diagrams annexed to the foregoing specification, for the purpose of substituting others contained

in another version of the same specification, which forms a continuation of "A Dissertation on the Construction of Locks, containing, FIRST-Reasons and Observations, demonstrating all locks which depend on fixed wards, to be erroneous in principle, and defective in point of security.

SECONDLY-"A Specification of a lock constructed on a new and in infallible principle, which, possessing all the properties essential to security, will prevent the ruinous consequences of HOUSE ROBBERIES, and be a certain protection against thieves of all descriptions: by Joseph Bramah," which was published soon after the date of the first patent.

A second edition of this interesting, and now very scarce pamphlet, was published in the year 1815. We shall quote at some length from both editions, and shall conclude our description with numerous diagrams of the details of the lock as it is at the present time constructed, and with such additional explanations as may appear necessary.

At the time Mr. Bramah wrote the "Dissertation," house-breaking had risen to a most fearful height in London, which caused the public to examine into the nature of the fastenings to their doors, and to their money depositories.

The warded lock was the kind almost universally employed, Barron's being at that period but little known. That Mr. Bramah thoroughly understood the principle and the defects and insecurity of the warded locks is evident from his writings.

It would appear, from the following pages, that although he appreciated the ingenuity of Mr. Barron in the construction of his double-acting tumbler lock, yet that he considered it insecure, from the circumstance of the tumblers having a uniform motion, and there being presented with a face which tallies exactly with the key.

"But if the variations of locks in which the bolt is guarded only by fixed wards could be multiplied to infinity, they would afford no security against the efforts of an ingenious locksmith. For though an artful and judicious arrangement of the wards, or other impediments, may render the passage to the bolt so intricate and perplexed as to exclude every instrument but its proper key, a skilful workman having access to the entrance will be at no loss to **fabricate(480)** a key which shall tally perfectly with the wards, as if the lock had been open to his inspection.

This operation may not only be performed to the highest degree of certainty and exactness, but is conducted likewise with the utmost ease. For the block or bit, which is intended to receive the impression of the wards, being fitted to the keyhole, and the shank of the key bored to a sufficient depth to receive the pipe, nothing remains but to color the bit with a preparation, which, by a gentle pressure against the introductory ward, may receive its impression, and thus furnish a certain direction for the application of the file.

The block or bit being thus prepared with a tally to the first ward, gains admission to the second, and a repetition of the means by which the first impression was obtained, enables the workman to proceed, until by the dexterous use of his file he has effected a free passage to the bolt.

In this operation he is directed by an infallible guide; for, the pipe being a fixed center on which the key revolves without any variation, and the wards being fixed likewise, their position must be accurately described on the surface of the bit which is prepared to receive their impression. The key therefore may be formed and perfectly fitted to the lock, without any extraordinary degree of genius, or mechanical skill. It is from hence evident, that endless variations in the disposition of fixed wards are not alone sufficient for the purpose of perfect security.

I do not mean to subtract from the merit of such inventions, nor to dispute their utility and importance. Every approach towards perfection in the art of lock-making may be productive of much good, and is at least deserving of commendation and encouragement; for if no higher benefit were to result from it, but the rendering that difficult or impossible to many, which is until practicable and easy to *a few,* it furnishes a material security against those from whom the greatest mischief and dangers are to be apprehended.

“The first claimant to merit in this branch of mechanics is Mr. Barron, whose lock is undoubtedly, and beyond all comparison, more excellent and more secure than any lock that ever was in use before his invention was made known. An observation or two upon Mr. Barron's lock will however illustrate what I have said on the subject of fixed wards, and prepare my readers to comprehend more readily the principle on which my own lock is constructed."

It appears from the object of improvement which employed Mr. Barron's attention in the construction of this lock, that he was aware, and as sensible as I am of the impossibility of guarding the avenues to the bolt so effectively by fixed wards as to prevent all access to it. Leaving the entrance and passage to the common protection of wards and outworks, his ingenuity has been wholly applied to the interior fortification of the bolt, by a new and judicious application of additional tumblers.

These are a kind of grapple, by which the bolt is confined as well in its active as its passive station, and rendered immovable, until set at liberty by the key. One of these instruments is commonly introduced into all locks that are of any use or value; it is lodged behind the bolt, and is governed by a spring which acts upon the tumbler, as the tumbler acts upon the bolt.

The application, therefore, of any force to the tumbler, which is superior to the force of the spring, will cause it to quit its hold, and set the bolt at liberty. And in this operation no skill or nicety is required to ascertain the degree of force to be applied; for it matters not how far the tumbler is lifted above the point at which it ceases to control the bolt.

In Mr. Barron’s lock the case is otherwise. He has not only improved upon the practiced method of applying the tumbler, but has given it an office which is perfectly new, and of more importance to its security than any impediment, which art can oppose to the introduction of a false key.

Instead of leaving his tumblers liable to be forced to an indefinite distance from the point at which they cease to control the bolt, he has confined their action within a circumscribed space, cut in the center of the bolt, of a dimension barely sufficient to the purpose they are intended to answer.

This space or groove is, in form, an oblong square, and is not only furnished with niches on the underside, into which the hooks of the tumblers are forced by the spring as in other locks, but is provided likewise with correspondent niches on the upper side, into which the hooks are driven, if any greater force be applied to the tumblers than is required to disengage them from the bolt.

Hence it becomes absolutely necessary in the fabrication of a false key that the pressure of the extreme point of its bit on the tumblers be proportioned with the greatest degree of

exactness to the point of height to which they must be raised, to release the bolt. Otherwise the power which disengages the hooks on the one side will fix them on the other, and until leave the bolt immovable.

This improvement, which does great credit to Mr. Barron's mechanical skill and invention, being as useful and important in effect as it is new and curious in principle, must be admitted by every competent and impartial judge to be a very valuable acquisition to the art of lockmaking. But greatly as the art is indebted to the ingenuity of Mr. Barron, he has not yet attained that point of excellence in the construction of his lock which is essential to perfect security.

His improvement has greatly increased the difficulty, but not precluded the possibility of opening his lock by a key made and obtained as above described. An impression of the tumblers may be taken by the same method, and the key be thence made to *act* upon them as accurately as it may be made to tally with the w*ards.* Nor will the practicability *of* obtaining such a key be prevented, however complicated the principle or construction of the lock may be, whilst the disposition of its parts may be ascertained, and their impression correctly taken from without.

I apprehend the use of additional tumblers to have been applied by Mr. Barron as a remedy for this imperfection because a less object would not have been worthy the exercise of his great talents and ability; and because (if such were his intentions) he did not overrate the effect which the cause was capable of producing.

He seems evidently to have conceived the **principle(481)**, but has certainly failed in the execution. For, by giving a uniform motion to the tumblers, and presenting them with a face which tallies exactly with the key, they until partake in a very great degree of the nature Of fixed wards, and the security of his lock is thereby rendered in a proportional degree defective.

To make these remarks more intelligible, I must ask my readers to suppose the key, with which the workman is making his way to the bolt (by the process above described) to have passed the wards, and to be in contact with the most prominent of the tumblers. The impression, which the slightest touch will leave on the key, will direct the application of the file, until sufficient space is prepared to give it a free passage.

This being accomplished, the key will of course bear upon the tumbler which is most remote; and being formed by this process to tally with the face, which the tumblers present, will acquire as perfect a command of the lock as if it had been originally made for the purpose. And the key, being thus brought to a bearing on all the tumblers at once, the benefit arising from the increase of their number, if multiplied to fifty, must inevitably be lost; for, having but one motion, they can act only with the effect of one instrument. But nothing is more easy than to remove this objection, and to obtain perfect security from the application of Mr. Barron's principle."

From this last passage it would seem that Mr. Bramah had some idea that Barron's lock was capable of being made perfectly secure by some easy method.

If the tumblers, which project unequally, and form a fixed tally to the key, were made to present a plane surface, it would require a separate and unequal motion to disengage them from the bolt. Consequently, no impression could be obtained from without that would give any idea of their positions with respect to each other, or be of any use even to the most skilful and experienced workman in the formation of a false key.

"The correction of this defect would rescue the principle of Mr. Barron's lock, as far as I am capable of judging, from every imputation of error or imperfection; and, as long as it could be kept unimpaired, would be a perfect security. But the tumblers on which its security depends, being of a slight substance, exposed to perpetual friction as well from the application of the key as from their own proper motion, and their office being such as to render the most trifling loss of metal, fatal to their operation, they would need a further exertion of Mr. Barron's ingenuity to make them durable."

It is evident that at this period Mr. Bramah had not conceived any other **method of picking(482)** locks, than by taking impressions of the fixed obstacles to the passage of the bolt and the fabricating of a skeleton key. The mechanical or tentative method was then unknown.

"The idea of constructing a lock that might resist every application and effort of art, was first suggested to me by the alarming increase of house robberies; which, there is great reason to believe, are as often perpetrated by perfidious servants, or accomplished by their connivance, as by any means

that are used by the common house-breaker. In this view of the evil to be remedied, it was evident that a lock or fastening, which might effectively exclude the one, would be no security against the other; and that no lock would completely answer its intended purpose, unless a free and deliberate access to the keyhole could be rendered as useless to the purpose of obtaining a key by impression, as the pick-lock, and other instruments of mischief, may be rendered (to the purpose of opening, the lock) by the multiplicity. and intricacy of its wards."

The hasty execution of a midnight robbery, in which the servants of a family do not act a part, will not allow sufficient time, (if proper instruments were at hand) to overcome the difficulties which ingenious locksmiths have opposed to foreign invaders. My chief attention, therefore, was applied to contrive a security against the advantage which *a* domestic enemy possesses, in the opportunity of executing his purposes at his leisure.

Practicable as I conceived this to be, I did not venture to attempt it by any means which had hitherto been found ineffectual. I had not the presumption to imagine that I could give perfection to an instrument, which men of much greater knowledge and ability had left defective. I was, therefore, as solicitous to avoid their *excellences,* as to escape their imperfections which are so blended in the best locks, as to make it impossible to adopt the one, without falling into the other.

A very little thought on the subject convinced me that my success would depend on the application of a Principle as dissimilar as possible to that by which other projectors had in vain sought to attain perfection in the art of lock making. As nothing can be more opposite in principle to fixed wards, than a lock which derives its properties from the motion *of* all its parts, I determined that the construction of such a lock should be the subject of my experiment.

In the prosecution of my purpose, various models were constructed, and I had the satisfaction to receive from the least perfect of them the clearest demonstration of the truth and certainty of my principle. The exclusion of wards made it necessary to cut off all communication between the key and the bolt; as the same passage which (in a lock simply constructed) would admit the key might give admission likewise to other instruments.

The office, therefore, which in other locks is performed by the

extreme point of the key, is here assigned to a lever, which cannot approach the bolt until every part of the lock has undergone a change of position. The necessity of this change to the purposes of the lock, and the utter impossibility to effect it otherwise than with the proper key, are the points to be ascertained by a specification of the component parts of the movement, and an explanation of their respective offices.

"Among the various methods of applying the principle of motion, in the construction of locks, which have yet occurred in my practice, I think those described in the subjoined plates are to be preferred for their simplicity."

"The first plate shows the interior face of a lock which was constructed at a very early period of my experiment, and was intended merely as a model to try the efficacy of the principle; but, to my great admiration, it turned out a complete instrument of security, and gave the clearest demonstration that the principle was certain and infallible."

"The lines which cross the face of the lock (figure 119) represent six levers, which are united in a joint, and turn on a common axis. Each lever rests on a separate spring of sufficient strength to sustain its weight, or, if depressed by a superior force, to restore it to its proper position, when that force has been withdrawn."

The curve F represents a frame through which the levers are carried by separate grooves or passages; these grooves are exactly fitted in their width to the thickness of the levers, but are of sufficient length to allow them a free motion in a perpendicular direction, whether lifted by the elastic power of the springs on which they rest, or sunk by the pressure of a superior weight from above.

The part which projects from the opposite side of the joint, inserts its extreme point in the bolt at B, and is a lever of a different form, which acts in subordination to those above described; to this lever, two offices are assigned; the one to keep the bolt in a fixed and immovable position in the absence of the key; the other to give it its proper motion when the key is applied.

The joint or carriage of the levers, and the springs on which the levers bear, are fixed on a circular platform, P, which turns on a center, and in its motion impels the bolt in either direction,

by means of which the lever is projected from the joint before-named.

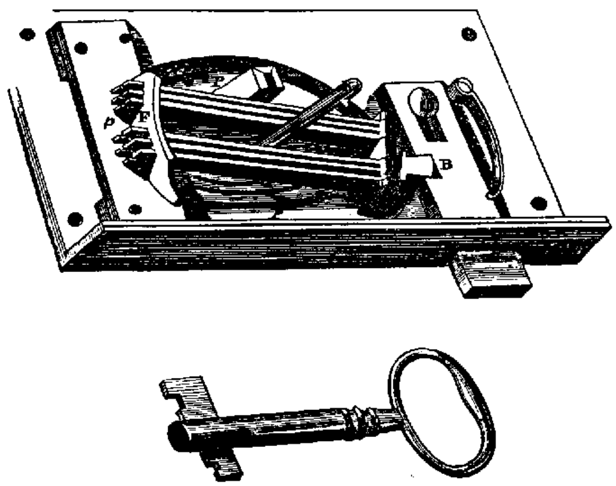

Figure 119. Bramah's First Model

"To give this machine the property of inviolable security, it was necessary to subject its motion to some restraint which the key only could remove. This power is lodged in the part *p*, which is a thin plate, bearing at each extremity on a block, and having, of course, a vacant space beneath, equal in length to the thickness of the blocks on which it rests."

"This plate is applied either to check or to guide the motion of the machine, and these opposite offices are thus performed. On the edge of the plate, which faces the movement, six notches are expressed, into which the points of the levers projecting beyond the frame are received; and whilst they are so confined, the motion of the machine is totally suspended, and the bolt so fixed, as to defy every effort of art or force to move it."

The necessity of the proper key to the purpose of opening this lock, and the impossibility of effecting it by other means, will be clearly seen from the process by which the machine is put in motion. It is to be observed that each lever has a notch expressed on its extreme point; and that those notches are disposed as irregularly as possible.

To give a capacity of motion to the machine these notches must be brought parallel to each other, and by a distinct and unequal pressure upon the levers be formed into a groove, in a direct

line with the edge of the plate *p*, which the notches are exactly fitted to receive. The least motion of the machine, whilst the levers are in this position, will introduce the edge of the plate into the groove; which, controlling the power of the springs, will give liberty to the levers to move in a horizontal direction, as far as the space between the blocks which support the plate *p* will admit, and which is sufficient to give the machine a power of acting on the bolt.

The impossibility of thus bringing the notches expressed on the points of the levers, to fall into a direct line, and to form a groove which shall perfectly tally with the edge of the plate *p* by any other means than the application and impulse of the key, is the principle of security which constitutes the peculiar excellence of the lock.

"The key (figure 119) exhibits six different surfaces on its bit, against which the levers are progressively admitted in the operation of opening the lock; the irregularity of these surfaces describes the distinct and unequal degree of pressure which each level requires to bring them to their proper bearings, for the purpose of putting the machine in motion."

It hence appears that unless the various heights of the surfaces expressed on the bit of the key are exactly proportioned to the several distances to which the levers must be carried to bring their notches into a direct line with each other, they must remain immovable; and, as one stroke of a file is sufficient to cause such disproportion as will prove an insurmountable impediment to their motion, I may safely assert that it is not in art to produce a key, or instrument, by which a lock, constructed on this principle, can be opened.

“It will be a task indeed of great difficulty, even to a skilful workman, to fit a key to this species of lock, though its interior face were open to his inspection; for the levers being raised by the subjacent springs, to an equal height in the frame *F*, present a *plane* surface; and, consequently, convey no direction that can be of any use in forming a tally to the *irregular* surface which they present, when acting in subjection to the proper key."

Unless, therefore, a method be contrived to bring the notches, expressed on the extreme points of the levers, in a direct line with each other, and to retain them in that position until an exact impression of the irregular surface which the levers will

then exhibit can be taken, the workman will in vain attempt to fit a key to the lock; or, by any effort of art, to move the bolt.

When it is considered, that the process will be greatly impeded, and may perhaps be entirely frustrated, by the action of the springs, it must appear that great patience and perseverance, as well as great ingenuity, will be required, to give any chance of succeeding in the attempt. I do not state this circumstance as a point essential, or of any importance to the purpose of the lock, but to prove more clearly what I have before observed upon its principle and properties.

If such difficulties occur to a skilful workman, as to render it almost, if not altogether impracticable to form a key when the lock is open to his inspection and its parts accessible to his hand, it pretty clearly demonstrates the impossibility of accomplishing it, when no part of the movement can be touched or seen.

It will naturally be imagined by the reader that the same difficulties which occur in the formation of a key in the second instance, must have been experienced by the maker of the lock; and that, however insuperable they may be to other workmen, they were easily conquered by him. But the contrary is the case.

No such difficulties occur in forming the original key; nor is any greater ingenuity exercised in the formation of it, than falls to the share of a common workman; for *the key is not fitted to the lock but the lock adapted to the key*; and this is effected by a mean, the most simple and the most easy that can be imagined.

The surfaces expressed on the bit of the key are worked as chance, or fancy, may direct, without any reference to the lock. The key being so completed and applied to the surface Of the levers, gentle pressure will force them to unequal distances from their common station in the frame *F*, and sink their extreme points to unequal depths into the space beneath the plate *p*. Whilst the levers are in this position, the edge of the plate *p* will mark the precise point at which the notch, on each lever, must be expressed.

"The notches being cut by this direction, the irregularity which must appear in their disposition when the levers resume their station in the frame *F*, and the inequality of the recesses

expressed on the bit of the key, will be as a seal and its impression to each other."

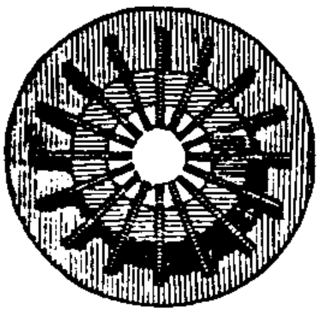

Figure 120. Top face of the Barrel or cylinder

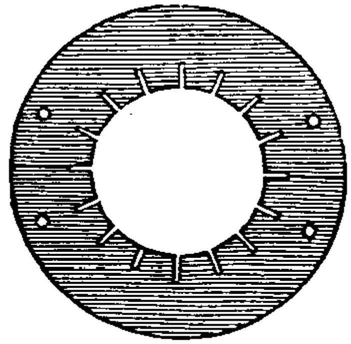

Figure 121. Locking-plate with Plain Notches or gatings

"Figure 120 represents the face of a circular block or barrel of brass, having a cylindrical cavity throughout, and divided from the center into sixteen compartments, separated by grooves passing also quite through, and fitted with as many steel sliders. The upper parts of these sliders project into the cylindrical cavity, and are elevated to be flush with the prominence in the center of the barrel. The notch in one part of this prominence receives the bit or lever on the key, which turns round the barrel in the operation of opening the lock.

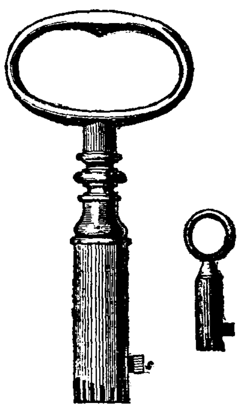

Figure 123.

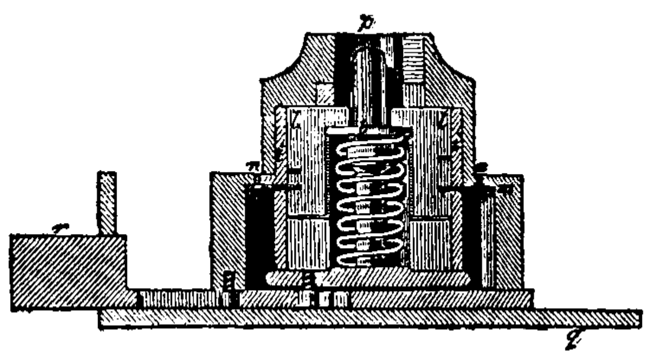

Figure 122. Bramah lock.

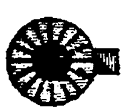

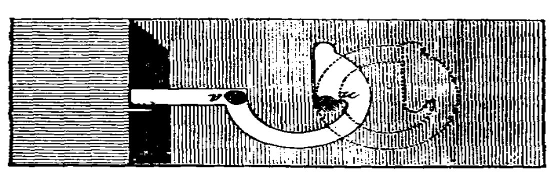

Figure 124.

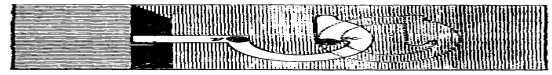

Figure 125.

"Figure 122 is a section of a complete lock; *i i,* is the brass barrel, as figure 120, having a groove cut in the middle of its spherical surface of a depth equal to the notches expressed at different distances on the outer edge of the sliders l l, and into which is fitted a thin plate of iron, shown at figure 121, and divided in halves for that purpose.

This plate is screwed to the cap or covering, m, at n n, with its internal edge to fit the cylindrical cavity, being previously notched thereon to correspond with the projection of the sliders in the groove. P is a pin attached to a brass plate at the interior end of the barrel; the plate is made to confine the parts in their places on that side, and the pin carries a small socket, *b*, on which the overhanging ends of the sliders rest, and which by the action of the spiral spring keeps the sliders buoyant.

The cap or covering plate, *m*, screws down to the external plate of the lock, *q*, limiting the upward pressure of the sliders, and protecting all the operative parts. When the barrel, *i i,* is moved round, the bolt, *r*, is thrown forward by a process which will be hereafter explained."

The description to figure 119 so well explains the action of the lock shown in figure 122, that we shall only here describe the analogous parts represented in the latter figure. The plate *n n,* (figure 122) corresponds to the plate *p*, in figure 119, and which in this lock is called the *lockinq-plate,* into which are cut sixteen notches, as shown in figure 121.

The sliders *l l* project into the cavity of the barrel, and are upheld in their respective grooves by the elastic power of the central spring on which they rest. All these sliders, as before observed, have a notch in the outer edge *d*, (figures 118 and 126) disposed as irregularly as possible, and all admit of pressure beyond the point which brings these notches parallel with the notches in the locking-plate.

By a distinct and equal pressure on the sliders, the notches therein must be formed into a groove in a line with the locking-plate *n n*, (figure 122) which those notches are exactly fitted to receive, before a revolving motion can be given to the

barrel or cylinder. This can only be performed by the key, which is represented in figure 123, and its indented point or extremity corresponding with the depths of the notches is seen at figure 124.

It will be recollected that the upper ends of the sliders overhang, or project into the cylindrical cavity which forms the keyhole; when the key therefore is applied, it must of course encounter these interior projections. Its extremity being notched in exact proportion to the several distances to which the sliders are to be carried, it will, when pressed forward, force the sliders to unequal distances from their bearings, and bring the notches on their exterior projections in a direct line with each other, and parallel with the plate, leaving the barrel at liberty to be carried round by the bit or lever on the key, (see *s*, figure 123) and which fits for that purpose into the notch on the prominence of the barrel, as explained in the description of figure 120, serving at the same time to stop the key at its proper point of pressure.

When the key is withdrawn, the sliders, of course, resume their station by the reaction of the spring, and the barrel returns to its confinement."

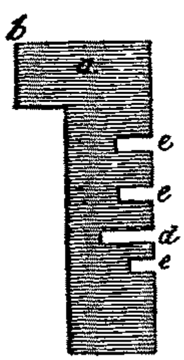

Figure 126. Steel Slider

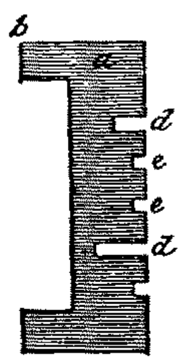

Figure 127. Steel Slider

Figure 128. Section of a Steel Slider

Figure 126 represents one of the sliders l l, (figure 122); b is the nib which projects into the keyhole; d is the notch. Figure 127 is a similar slider for a two-sided lock, and figure 128 shows a section of a slider split in its thickness so that it may move up and down in its groove with a slight friction, and thereby not fall simply by its own weight.

"Figure 129 is a plan of a complete lock, with a part of the cap or covering removed, to show the original mode of applying this

principle of security. The dotted lines on the bolt are the spring and tumbler, situated beneath, and having the same office as in the common lock. The lever *x* which is firmly attached to the barrel, represents the web or bit of an ordinary key, and which being carried round with the barrel, takes hold of the bolt in the notch, which it releases by lifting up the tumbler, and projects or withdraws in its revolution.

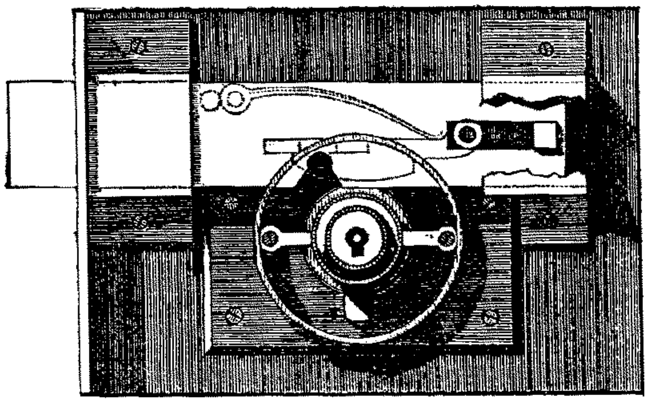

Figure 129. Complete Lock, showing the original mode of construction

As circumstances might by possibility occur, where ingenuity could gain access to the tumbler and release the bolt without attempting the principle of security, locks are now fabricated in the manner shown at figures 122 and 125, a method which can only be accomplished on this principle, and which vies in importance with the original invention.

"Figure 125 is a plan of the bolt of the lock figure 122. The point u is a pin fixed in the bottom of the barrel e e; and which, when the barrel is carried round, moves in the direction of the dotted circle, and, and of course, carries the bolt to and from with it. The pin v is attached to the covering plate, and serves to steady the bolt in its motion. The principle of security is thus made to restrain the bolt without the intervention of any other agent; and the slightest inspection must convince that no power can move the bolt, but that which also puts in motion the barrel.

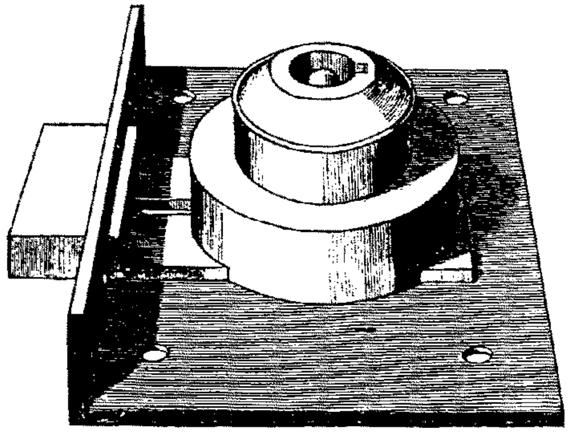

Figure 130. Drawer or Until Lock--complete

It would appear that previous to the publication of the second edition of the "Dissertation," a main central spring had been substituted in the place of the separate spring to each slider. In the words of the writer of the article "Lock" in the *Encyclopaedia Britannica*,

"Such was Bramah's lock as it first came extensively into use, and as it continued for many years, employed for the most important purposes, and by the most distinguished persons. At length an advertisement appeared in the public papers, requesting those who had lost keys of Bramah's locks, not, as had hitherto been done, to break open their doors or drawers, but to apply to the advertiser, who would undertake to save this destructive process by picking; and it appeared that an individual of great dexterity could perform this operation almost with certainty.

The effect of this discovery on the demand for the locks may easily be imagined; but the effect it had in stimulating ingenuity to provide a remedy is one of the best illustrations of the Proverb that necessity is the mother of invention.

Within a few days or weeks, Mr. Russell, who was at that time employed in Mr. Bramah's establishment, devised an alteration which at once, and without any expense, entirely overcame the difficulty, and converted the lock into one of perfect security. This contrivance is the most simple and extraordinary that ever effected so important an object; but before we describe it, we will endeavor to explain what has been called the *tentative* process of lock-picking, and which has been so successfully applied to Bramah's locks.

To do this, we will refer to the diagram (figure 131) in which *a* represents a bolt fitting loosely an outer-case, and tending to move in the direction of the arrow. It is, however, prevented by three studs, which are moveable upwards and downwards by their knobs, 1, 2, and 3; but it would be free to move if these studs were elevated or depressed to correspond with the notches made in the end of the bolt.

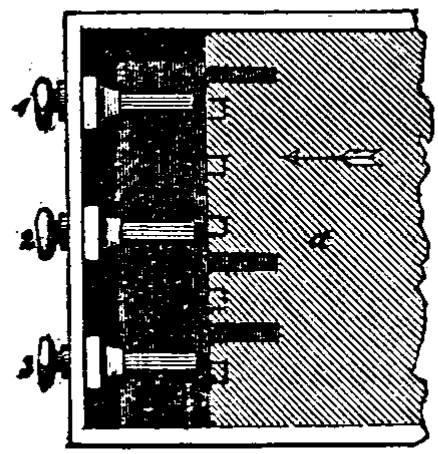

Figure 131. Diagram to explain the false notches

Now, if the case were closed, it would be perfectly easy to place these studs in the requisite position by the following process: Apply a pressure to the bolt, which can be done in any lock, tending to move it for unlocking. This will, of course, be resisted by the studs 1, 2, 3, but not by all equally; it will in fact be resisted by only one of them; the necessary imperfections of all workmanship would prevent more than one at a time from coming into sensible contact with the bolt.

Having therefore applied pressure to the bolt with one hand, with the other the operator would ascertain which of the studs was most bound by the pressure. This would be easily done, and then he would move the stud gently up and down until he felt it catch in the notch to which it belonged. The bolt would move until the next most prominent stud received it, which would be tracked to its notch in the same manner, and so on until all were disposed of.

“By a similar process the picking of Bramah's lock was effected. A tendency to revolve was given with some force to the barrel; then by means of a pair of small forceps, the several sliders were tried, and it was ascertained which was most detained by the pressure against the locking-plate. That which offered most

resistance was gradually depressed until its notch was felt to hang itself upon the locking-plate, and so on until the whole were depressed in succession, exactly as they would have been depressed simultaneously by the key.

Returning to figure 131, it will be easily understood that if, in addition to the three principal notches, a number of **shallower notches(483)**, as indicated by dots, be made equal in depth to any possible inequality in the projection of the studs, the process we have described is entirely prevented, because it will be perfectly impossible for the picker to tell whether he has brought the stud to one of the deep notches or to one of the shallow or false notches, and he will of consequence be entirely baffled.

This was the happy suggestion to which we have alluded. This will explain the two or three shallow or false notches which now appear in the edges of Bramah sliders, (see *e e e*, figures 118, 126, and 127) and which require corresponding false notches, or rather false widening in the notches of the locking-plate."

The Bramah lock has thus far been described in the words of its inventor. Its importance will induce us, at the expense of being considered too prosy, to illustrate and explain one of these locks, as at the present time constructed, and we shall do so as briefly as possible.

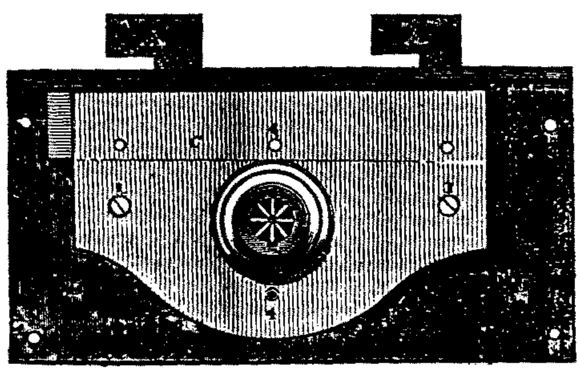

Figure 132. Exterior of a Bramah Box or Desk Lock

Figure 132 represents the exterior of a box or desk lock, a variety for which the Bramah principle is peculiarly adapted. The neat appearance of the nozzle, the small keyhole, and the corresponding small key, are properties not to be overlooked.

A A shows those portions which rise from the bolt through the

holes in the fore-end or selvage of the plate B B of the lock, upon which the bolt has a backward and forward motion. c is the cap, which is secured to the back-plate by two screws at 1 1. The cylindrical projection or barrel, D, contains the whole of the security parts of the lock. The pins, 4 4, are employed for securing the locking-plate f f (figure 133) firmly in its position between the cap c and the back-plate B B.

Figure 133 shows several of the internal limbs of the lock separately. *E* is the cylinder or barrel, with the hole in its center for the key, and into which the steel sliders *a a a a* (figure 134) project from the grooves cut inside the cylinder.

As mentioned before, the sliders are split open about half-way up, and since the year 1817, besides the principal notch or main gating, there two or three false notches cut in addition as before shown in figures 126 and 127, and at 3 3, (figure 134).

F is the circular plate of metal into which the drill-pin is riveted; the former being secured to the bottom of the barrel by two screws. c is the stud which works in that portion of the bolt d, (figure 135) by which it is moved backwards and forwards. 6 is the central spring coiled loosely round the drill-pin; the pressure of the spring forces up the collar 7, on which the upper part or nibs of the sliders 8 (figure 134) rest.

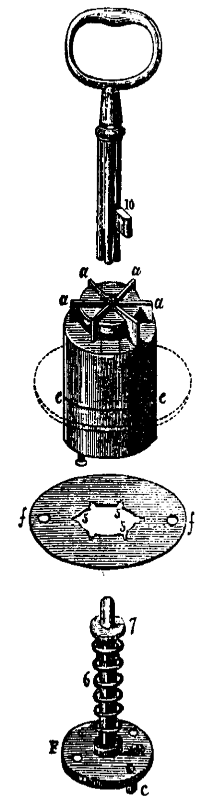

Figure 133. Detai interior of a Br

The locking-plate f f has six notches at 5 5 5, which, in consequence of the false notches in the sliders, are made wider or more open for the purpose of increasing the difficulty of opening the lock by any other instrument than its own key. By comparing this figure with figure 121, the difference between the former and the locking-plate as first used will be understood.

Figure 134. Stee

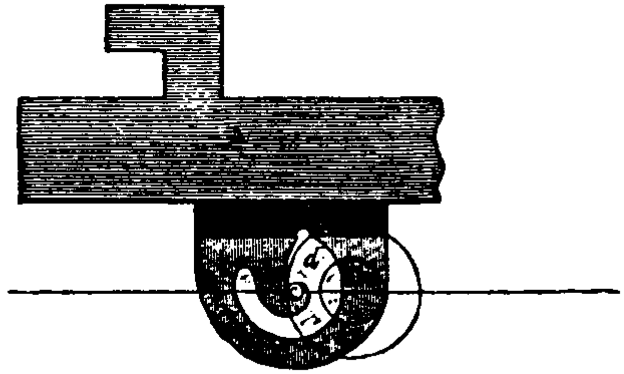

Figure 135. The Bolt

The locking-plate fits upon the cylinder at e e, (figure 133). The key, as shown in the upper part of figure 133 has six notches or cuts at the end of its pipe or shank, which are cut to different depths to correspond with the true notch on each slider. The small projection, 10, near the end of the pipe, is fitted to enter the notch D in the cylinder (figure 133).

The bolt of the lock, (figure 135) when locked, is prevented from being forced back by the stud c in the bottom of the plate P, through the cylinder coming in a direct line with its center of motion, and in this position no force applied to drive the bolt back would have any tendency to turn the cylinder around.

We consider the adoption of the central spring a great improvement, and one that quite accords with our views in relation to inventions, as it was effected, not by the addition of more parts to the mechanism, but in a lock with sixteen sliders, by actually dispensing with fifteen limbs.

The additional security thus obtained, consists in obliging the operator, who attempts to pick the lock by depressing the sliders separately by means of any small pointed instrument, and who by chance might bring two or more of them to the proper depth for turning round, if he pressed any one too low, so that the true notch went below the locking-plate, to release the central spring *6*, (figure 133). This would force the whole number of sliders to their original position, and would compel him to commence the operation de novo.

After Mr. Chubb read his paper "on the construction of locks and keys," in 1850, before the Institution of Civil Engineers, an interesting discussion followed on several of the principal locks, when Mr. Farley observed, relative to the Bramah lock,

“that the mechanism of locks had been a favorite subject with him, from an early period of his studies, when he had the good fortune to be intimate with Mr. Joseph Bramah, and had acquired a knowledge of his locks, which were then in high repute. The secret workshops wherein the locks were manufactured contained several curious machines for forming parts of the locks, with a systematic perfection of workmanship which was at that time unknown in similar mechanical arts.

These machines had been constructed by the late Mr. Maudslay with his own hands, whilst he was Mr. Bramah’s chief workman, The machines before mentioned, were adapted for cutting the grooves in the barrels, and the notches in the steel plates, with utmost precision. The notches in the keys, and in the steel sliders, were cut by other machines, which had micrometer screws, so as to insure that the notches in each key should tally with the unlocking notches of the sliders in the same lock. The setting of these micrometer screws was regulated by a system which insured a constant permutation in the notches of succeeding keys, in order that no two should be made alike.”

Mr. Bramah attributed the success of his locks to the use of those machines, the invention of which had cost him more study than that of the locks; without the machines, the locks could not have been made in any great number with the requisite precision, as an article of trade. There was great originality in those machines, which were constructed before analogous cases (beyond the clock-maker’s wheel-cutting machines) were in existence.

He said further, that “the security of Bramah’s lock against being picked, depended upon the circumstance that its several sliders must, each one for itself, be pushed in so far and no further; but how far the lock afforded no indication. It was nevertheless very objectionable that the sliders should be so completely exposed to view.

It had been suggested that a universal false key for Bramah’s locks might be made with the bottoms of its several notches formed by as many small steel sliders, extending beyond the handle of the key, so as to receive pressure from the fingers for moving each one of the sliders within the lock, with a sliding motion in its own groove, independently of the others; and during such sliding motion a gentle force could be exert4d, tending to turn the barrel round.

Under such circumstances, supposing that the motion of the barrel

was prevented by any one slider only, that one having to resist all the turning force would be felt to slide more stiffly endways in its groove, and therefore it could be felt when its unlocking notch arrived opposite the steel plate, and left some other slider to begin to resist the turning force; such a circumstance presumed a palpable inaccuracy in the radiating correspondence between the notches in the steel plate and the grooves for the sliders in the barrel, which could not happen with Bramah's workmanship."

The universal pick above alluded to, is, without doubt, a most formidable instrument when employed on a badly-made or spurious Bramah lock. In the hands of a practical locksmith, or an ingenious amateur, the probability of opening such locks by its aid is certain.

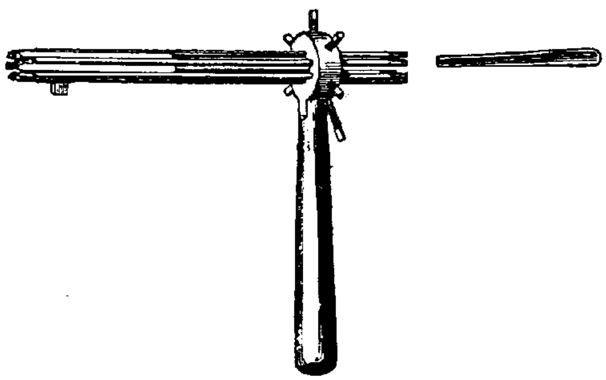

Figure 136. Universal Pick for a Bramah lock with Six Sliders

We shall merely illustrate and explain the instrument here, as all other particulars relating to its use will be found in the chapters on the Lock Controversy.

This ingeniously constructed instrument consists of a stem with six grooves, in each of which a sliding wire moves up and down. The stem and sliding wires are fitted into the cylindrical part of the handle *a*, and the sliding wires are held in any required position by the setscrews *e.*

In operating upon the lock, the bottom of the pick, *b*, is forced into the keyhole, when the bit *c* comes in contact with the neck of the barrel, which presses the cylinder, and the latter causes the steel sliders of the lock to bind more or less against the locking-plate.

The setscrews *e*, etc., all being released, a small handler is

screwed on to the end of one of the sliding wires at *d*, when a gentle pressure is applied to discover if that one binds. If not, the next is tried in the same way, and so on until the particular steel slider that binds is found, when it is gently set free, and the setscrew is turned round until the sliding wire becomes fixed in that position.

One slider being thus released, another of the remaining five will be found to bind in the same way as the first, when it is relieved in the same manner, and so on until the whole six are set free, when the pick becomes as complete a key as the true key itself. When the bottom of the pick, *b,* is put in the keyhole, it at once takes away the force of the central spring.

We must, however, mention, that the above pick will only do for a six-slide lock of the particular size of the pick; consequently, though it has been called "universal," a separate pick would be required for every lock which had more or less sliders, or which had a keyhole of a different diameter.

We have now so fully described and illustrated the Bramah lock, that we feel assured its merits cannot fail to be understood and appreciated by all our readers. It will be apparent that although many persons talk of opening the Bramah lock with a turkey quill, a pocket-pencil case, or other similar simple instrument, that it is only when these locks are made with wide slots in the locking-plate and sliders, or when the sliders are purposely made too short to reach the locking-plate, that they can so easily be opened with a pick of that description; or, as is the case with thousands of locks with "Bramah's Patent-Secure" stamped upon each, which are made without any sliders at all.

Many such locks(484), on examination, appear to be filled with sliders, but upon a closer examination, what appeared at first to be sliders are found to be only bits of iron wedged across the neck of the barrel. It will be readily conceived how all such locks can be opened by a quill or a pencil-case.

The principal cost in making a Bramah lock secure is the time consumed in carefully fitting the several internal parts, which careful fitting the lock is worthless, and it is to produce these locks at lower prices that the above deceptions are practiced.

A three-inch till lock with sliders, and well-made, is worth five shillings, whilst a lock of the same size and similar in external appearance with wide slots in the locking-plate and sliders, and

other parts as carelessly made, is worth but three shillings, and one without any sliders at all, only two shillings.

The public have to thank themselves, in the first instance, for the insecure and worthless locks they are furnished with, as they usually expect to be supplied with a genuine Bramah lock at the same price as the spurious imitation, and this remark will equally apply to all the other kinds of locks.

Instances have come under our observation, where locks of this description have been required, when the party giving out the order has stated that he did not care how they were made so that a certain price was not exceeded, for instance, two shillings for a three-inch box or desk lock. We only wonder that more robberies of ladies' cabinets and workboxes, gentlemen's writing desks and dispatch boxes, etc., do not occur.

In such cases the principle of the lock must not be condemned on account of the niggardly disposition of the purchasers, or the want of integrity on the part of the maker of the lock, or the manufacturer of the article to which the lock is attached. If the public wish to have good locks, they must give fair prices.

In concluding our remarks upon the Bramah lock, we feel bound to state that we consider it, when well-made, a most difficult lock to pick, even by a practiced and scientific locksmith. As to the merit of the invention, we cannot find words to express our admiration of the great mechanical skill and ingenuity of Mr. Bramah, so clearly exhibited in the beautiful construction of this lock. That he was no ordinary mechanic is evident from the number of his meritorious inventions.

He held, we believe, at one time, not less than **twenty patents(485)**, among which may be mentioned the hydraulic press; the force-pump; the beer-engine; the machine for numbering notes at the Bank of England (now in use); a patent pen, until in great demand; the mounted fire-engine, also now used; the water closet; a planing machine, extensively adopted; the ever-pointed pencil case; a slide cock, which has superseded the use of steam valves; and various other improvements in the details of the steam-engine.

We must not forget to mention **Mr. Russell(486)** in connection with the Bramah lock, who in the year 1817, as before named, introduced the false notches in the sliders as shown in figures 118, 126, 127, and 134, thereby increasing the security of the

lock so considerably. The value of this improvement, effected so simply and without any appreciable cost in the manufacture of the lock is of the greatest consideration.

It may be proper to remark that we shall so far depart from describing the various locks in their strictly chronological order of invention, as to describe the whole of the improvements introduced by the same inventor into the same lock, in their consecutive order.

BRAMAH'S SPECIFICATION, dated May 3rd, 1798.

This patent has two objects: the first is to make a lock that shall not require a key, which shall put all the sliders right simultaneously; and the second is for the construction of a kind of universal or changeable-bit key, by which the sliders shall be adjusted, one after the other, to a scale of variations supplied by the owner at the time of purchasing.

The patentee states distinctly in his Specification, that he abstains from giving any details, as he takes out the patent as a claim to the principle of such modes of constructing locks and keys, reserving to himself the right to make any mechanical arrangements for its proper carrying out that experience may show him to be the most suitable.

In the absence of any drawings or detailed explanations in the specification, we cannot tell how the " two objects " were to be effected, and from the circumstance of the present firm of Messrs. Bramah and Co. being ignorant of what the patent was for, we are inclined to think that the intentions of the patentee were never carried into operation.

TAYLOR's LATCH LOCK, invented about 1784.

The latch or spring bolt of door locks on the common construction (whether mortise, case, or rimmed locks) is very liable to be out of order as soon as the oil is dried up between the tumbler and tail of the latch, from the erroneous manner in which the tumbler is made to act; and more especially when the lower arm of the tumbler is engaged, for then the friction is very great, and the bolt very hard to be moved.

To remedy these defects, Mr. Taylor constructed "the tumbler and tail of the latch or spring bolt in such a manner that the lock might be constantly used for many years without any oil to those

parts, and always move alike both ways, that is, by turning the knob or handle either to the right or left, and with less force of the hand in turning it.

"The alteration which constitutes the difference between this lock and those in common use is, that the tumbler is reversed and the tumbler acts against two stubs fixed on the tail of the latch and thrusts it easily back, whether, the knob is turned to the right or left in opening the lock; behind the tail of the latch is also fixed a guide, having within it a groove wherein runs a small friction-wheel, serving to keep the latch in its direct situation, and lessen its friction; the arms of the tumbler are not so long as they are generally made, because the latch or spring bolt must move the easier by their being shorter.

“By the above construction, those parts of the tumbler and tail of the latch that are in contact move in a line, the nearest to the chord of a circle, whose radius is the arm of the tumbler, and consequently pass over the greatest space under the least angle possible. The friction-wheel before mentioned being placed on a stub rising from the tail of the latch, and in a line with the center of the tumbler, and having the spring that pushes the latch or bolt forward, touching also in the same line with the friction-wheel, is a still further improvement for all kinds of latch locks, though low-priced locks will do very well, according to this construction, without it.”

The inventor of this lock was rewarded by the Society of Arts with the silver medal.

MARSHALL'S SECRET ESCUTCHEON, Invented About 1784.

As before observed, this is one of the many attempts which have been made to construct a machine possessing the properties proposed by the Marquis of Worcester in No. 72 of his “Century of Inventions,” viz.:

“The owner, though a woman, may with her delicate hand vary the ways of coming to open the lock ten million times beyond the knowledge of the smith that made it, or of me who invented it.”

The construction of this escutcheon is an improvement on the principle of the common letter lock, and consists in allowing the owner to produce an almost infinite variety of **changes(487)** in one minute and in such manner “that even the maker would be as unlikely to open it as he would be of gaining the highest prize

in a lottery by the chance of a single ticket."

"A, (figure 130) the barrel in which the bar B slides; part of this barrel is concealed within the rollers, but the ends of it appear at a and b, figure 137. B, the bar with projecting teeth, by which the rollers C prevent its being drawn back till the nick in the recess is brought exactly over the tooth; the square end of this bar is seen at C, figure 138. C, a roller, of which there are five, each composed of two circle, the outer circle having four rows of letters at equal distances engraved on the surface, with small knobs, for the more commodiously turning the rollers round, the inner circle D being moveable within the outer one on the barrel A; to the surface of each of the inner circles is fastened a small spring d, serving to keep the outer circle in its place, till an alteration in the position of the letters, which are the foundation of the secret, is intended to be made; and within the inner circle is a recess to prevent the bar *B* being drawn back, unless the teeth and the nick are in their proper situations, at which time, by drawing back the bar by the square end *c*, (figure 138), which is otherwise retained in its proper place by means of the feather-spring *h*, the catch *e*, (figure 137) is released, and the door of the escutcheon is thrown open by the spring *g.*

Figure 137. Marshall's Secret Escutcheon.-(Back)

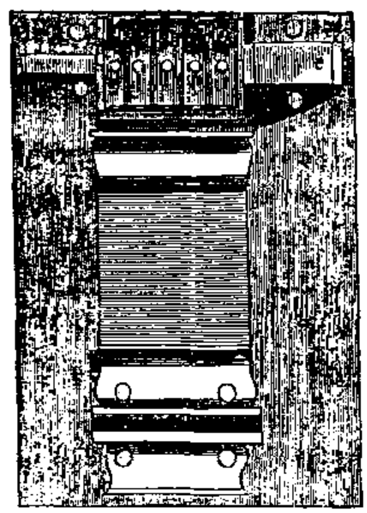

Figure 138. Marshall's Secret Escutcheon.-(Front)

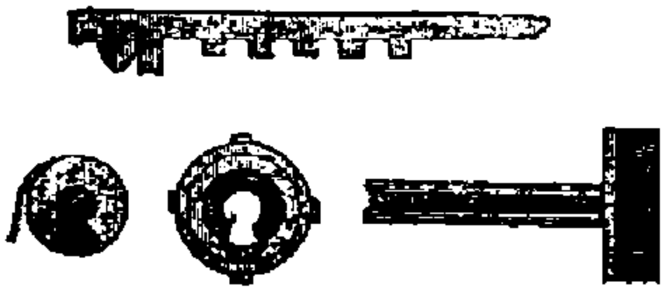

Figure 139. Details of Marshall's Secret Escutcheon

"When an alteration of the arrangement of the letters on which the secret depends is desired, the bar *B* must be held back by the square end *c*, while one or more of the outer circles are turned round until the letters chosen are uppermost. The escutcheon cannot afterwards be opened until that same arrangement is again made, and so on according to whatever situation of the letters the owner may choose."

"Hence, it is evident that whichever of the letters have been chosen must, at the time of opening the escutcheon, be brought in one line to the upper surface of the rollers; and then the bar being drawn back, the door of the escutcheon will be thrown open."

"Figure 137 represents the under or inner side of the escutcheon, and figure 138 the upper or outer side; and appears as when fixed over a lock, and covering the keyhole."

This escutcheon would be secure only so long as the combination could be kept secret. See the description of the letter-lock appears subsequently. The inventor received a bounty of ten guineas from the Society of Arts, in 1784, for this secret escutcheon.

BICKERTON'S FIRST LOCK, invented about 1784.

This was a good step in advance on the common tumbler lock, by adding to the common tumbler a double-acting limb at the back of the bolt, very similar to a detector. The front end of this limb, when at rest, presses against the main bolt, and holds it fast. If over-lifted by the tumbler, the back end of this limb grasps the bolt, and detains it until the exact height of the lift is discovered.

CORNWAITE'S LOCK, invented about 1784. Patent dated July 7th,

1789.

This lock comprises one of the most simple movements ever invented. Its construction is an improvement on the common tumbler lock, and consists of four levers, which are pivoted at one end, and at the other end have a *tongue* which works into a corresponding slot in the bolt-head. When the bolt is locked out, these tongues fit into the slot, and make the bolt, as it were, quite solid.

When unlocked, the levers are forced downwards by the springs. It is worth noticing that the curve in the bolt-head gives a wide range of combinations to this lock. There is no stump in the bolt, neither are there any slots or racks in the levers; and the peculiar construction admits of it being made particularly strong. This lock obtained a premium of ten guineas from the Society of Arts in 1784, though it does not appear to have been patented until 1789.

ROWNTREE'S LOCK, Patent dated February 23, 1790.

Rowntree's is a very elaborate tumbler lock, and contrasts remarkably with the simplicity of Barron's lock. This lock is constructed with tumblers in combination, with revolving discs or wheels. Its mechanism may be understood from the following description and engravings, which we have copied from Mr. **Tomlinson's Rudimentary Treatise on the Construction of Locks.**

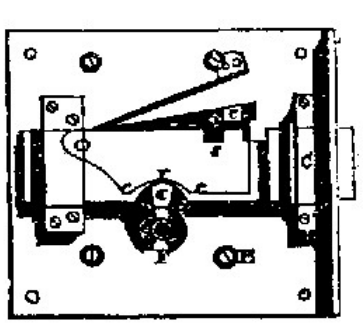

Figure 140.

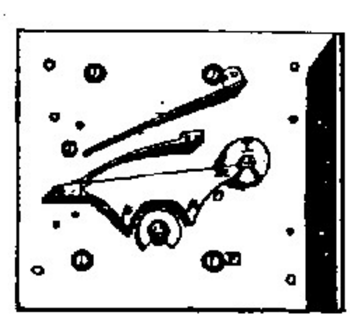

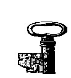

Figure 141.

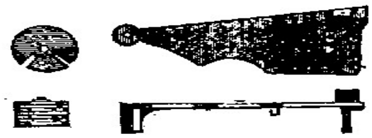

Figure 142.

Figure 143.

Figure

The same letters refer to the same parts in the several figures: A A is the plate which encloses the whole mechanism of the lock, and fastens it to the door; *B B* is the bolt guided in its motion by sliding under the bridges *C D*; *E E* are pillars which support a plate covering the works; *F* are the circular wards surrounding the center or key-pin; and *a* shows the position of the key, which, in turning round, acts in a notch *r* in the bolt, and propels it.

G, the tumbler, is a plate situate beneath the bolt, and moving on a center-pin at *d*; it has a catch or sump, *e*, projecting upwards, which enters the notches *f* or *g* in the bolt, and thereby retains the latter for backward or forward motion, as the case may be; *H* is a spring which presses the tumbler forward.

The key *a*, in turning round, acts first against the part *c c* of the tumbler, and raises it so as to remove the stump from the notches; it can then enter the notch *r* in the bolt, and move it. So far there is no particular security; but Mr. Rowntree sought to obtain it by the following means.

There is a piece of metal *h* fixed to the lower side of the tumbler, called the *pin;* when the tumbler is caught in either notch of the bolt, the pin applies itself to a cluster of small wheels I, fitted on one center-pin beneath the tumbler; the edges of these wheels stop the pin, and prevent the tumbler from being raised. But each wheel has a notch cut in its circumference I; and it is only when the wheels are so placed that all their notches lie in a right line that the pin can enter this compound notch and allow the tumbler to rise. The wheels must therefore be all adjusted to position; and this is effected by a number of levers, *k,* centered on one pin at *k.*

At the opposite end, each lever has a tooth *m* entering a notch in the wheel belonging to it; so that when any lever is pressed outward, it turns its wheel round. Now this pressure of the levers is brought about by a spring *n* applied to each; and when so pressed, the levers rest against a pin *o* fixed in the plate. The key is so cut as to determine the extent to which the levers shall act upon the wheels.

The key first operates from the curved part *p p* of the levers *k*, and, raising them, turns all the wheels, *I*, at once into the proper positions; in turning further round it then operates on

the part *c c* of the tumbler, causing the latter to rise and to release the bolt; and in turning until further round, it (the key) seizes the notch *r* of the bolt, and shoots it. The key is cut into steps of different lengths, as shown at *v v*; each step operates on its respective lever *k* in a different degree from the others; the notch at *s* acts upon the tumbler, and the plain part *t* moves the bolt.

BIRD'S LOCK, Patent dated October 29, 1790.

The peculiarity of this lock consists in the levers and springs being attached to the bolt, and moving with it, so that the bolt, the levers, and the springs, in locking and unlocking, all move together, and the stump which in other locks is generally fixed in the bolt, is, in this lock, fixed in the plate. Before the bolt and the levers, is fixed a contrivance which we shall designate the grate, through which the steps of the key have to pass to reach the bolt and the levers. This "grate " is identical with the "barricaded guider" of Mallett's lock, patented at a subsequent period.

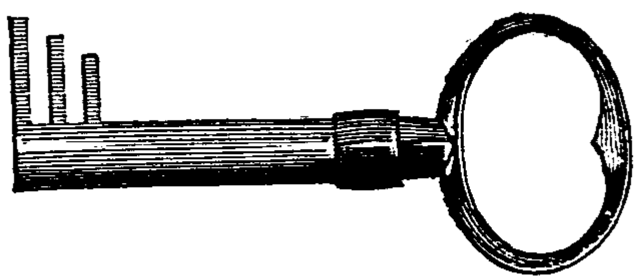

Figure 145. Key to Bird's Lock

FERRYMAN'S LOCK, Patent dated July 19, 1791.

This lock is described as "acting by lever, tooth-wheel, and drop, chiefly without springs, simple in principle, and not liable to be injured by accident or friction, applicable to prisons and other places where strong fastenings are required."

BICKERTON'S SECOND LOCK, invented about 1792.

The construction of this lock is an improvement on Mr. Bickerton's first. It has a double-acting tumbler, having a stump on each end of it, and works in racks at the front end of the bolt, and also at the back of it. The center of motion is in the middle of the tumbler. There is a pin fixed fast in the

lock-plate, and the bolt in locking and unlocking is lifted over it, thereby giving to the bolt an oscillating motion. Should the true position of the tumbler be found, the bolt will not move until lifted over the fixed pin.

ODELL's LATCH, invented about 1792.

This invention is commonly called, and is well known by the name of, a French latch, and is very curiously constructed. The keys are cut of various patterns in the form of letters, figures, etc., with secret contrivances attached in various ways before the keyhole, but which in use, are found to be very objectionable, more especially in the dark.

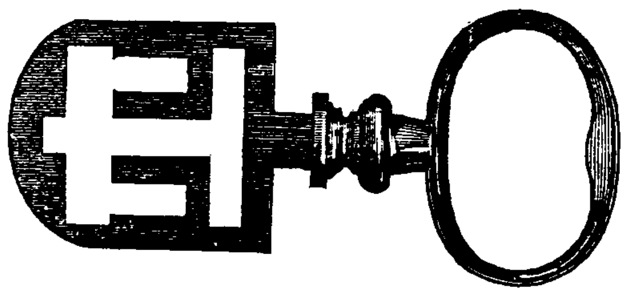

Figure 146. Key to French Latch

The peculiarity of the **construction(488)** consists of a large tongue, which drops down behind the keyhole, and has merely to be lifted up to unlock. This is the night-latch, which gentlemen who have lost their keys, open with their address cards, a very convenient substitute when used by themselves, but not a very desirable safeguard to the domicile.

MASON'S LATCH, invented about 1796.

The improvement introduced by Mr. Mason was chiefly in the latch bolt, by jointing it to a swinging piece similar to a "follow," to prevent friction, and which required considerably less action in working the knob. Also by adding a bar across the gating of the main bolt above and below, one fast and the other loose. To prevent a false key opening the lock, the bolt, if preferred, was shot twice, and the lock required **two keys(489)**, one of which locked out and the other, was a master key. It is supposed that the “shifting or reversing bolt" was the invention of Mr. Mason.

TURNER's LOCK, invented about 1798.

This is what is called a flush-bolt lock, i.e., the bolt of a desk lock, when unlocked, does not project above the fore-end or selvage, as in most other locks of this kind. The peculiarity of the construction consists in the key working within a cylindrical cup, which fits within another cup. There are three or more levers.

The outer cup, which is moveable, drives the bolt, whilst the inner one is stationary. The levers receive a sliding motion at right angles with the face of the cups. The lock has a nozzle similar to Bramah's, and the key is also as convenient in size. It must be noticed that the key reaches to and moves inside the levers.

PEDLEY'S LOCK, invented about 1798.

Pedley's lock was an ordinary tumbler lock. The peculiarity was the key. The bit of the key was jointed to the pipe or shank, and the lock had no drill-pin. A round tube was fixed on the cap, into which the key was inserted, and when it reached the back-plate, the key-bit moving in the joint at a right angle reached the bolt and tumbler, and required the reverse action of the key to act on the spring bolt on the ancient secret principle, before the lock could be opened.

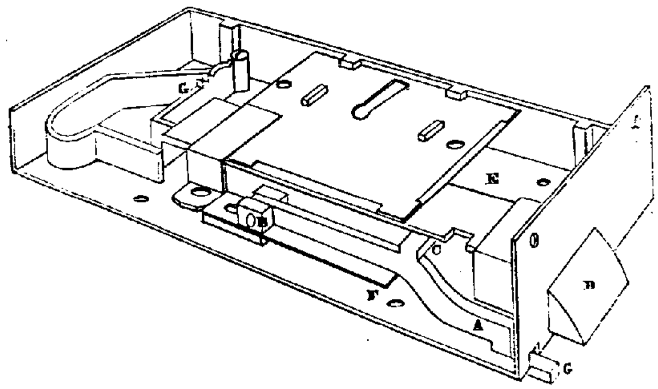
BULLOCK's LEVER LOCK-BOLT, invented about 1800.

The lever lock-bolt is for folding doors, by means of which the upper and lower bolts are withdrawn with ease by the turn of a common door handle, and the same bolts shot and fastened merely by pressing the door to its proper place.

The handle, in external appearance, resembles the round door-handles in general use; when moved, it acts in a double chain 'follow;' the lower chain communicates with a lever which has a pivot near its center, the extremity of which lever raises up the lower bolt of the door when shut.

The upper chain communicates with another lever connected with the upper bolt, which it draws down by moving on a pivot near the center of the lever; and thus the bolts are opened. The upper bolt being stopped down by a reliever at the top of the door, the bolts are prevented from grating either at the top or bottom of the door. On shutting the door, the reliever is pressed in by the wood-work at the top of the door, which sets the bolts at liberty. The lower bolt then falls down, and the upper bolt is

propelled by two springs that act upon the upper and lower levers, and the door remains firmly bolted.



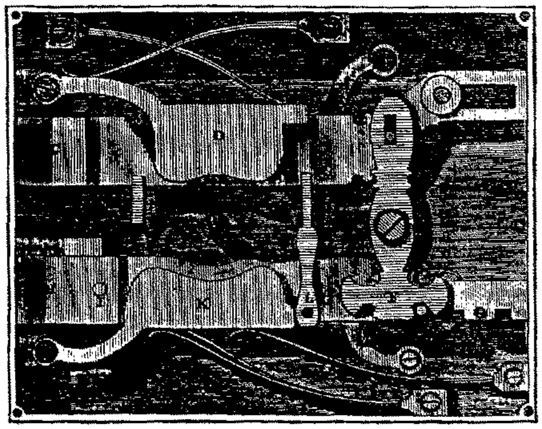


Figure 147. Bullock's Lever Lock-Bolt

A great advantage arises in the use of this invention, from the whole of the machinery acting upon pivots, which are not liable to rust, but allow a regular and easy motion to the bolts.* The inventor of this lock was rewarded by the Society of Arts with a bounty of ten guineas.

ARKWRIGHT'S LOCK, invented about 1798.

This is a "double-bolted" lock, with a double-bitted key. Its peculiar construction will be understood from figure 148.

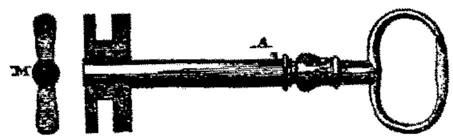

Figure 148. Arkwright's Lock

"*A*, the pointer on the shank of the key; *B* the pin on which the key turns; *C*, the top-bolt of the lock; *D*, the upper tumbler for the top bolt; *E*, another tumbler for the top bolt, and placed underneath it; *F*, a lever which works both bolts, and moves on a center *G*; *H*, the lower bolt, with a joint, *I*, upon its head; *K*, the lower tumbler, with two joints *L L*, which fall into two notches of the top-bolt."

"Underneath the lower-bolt is another tumbler similar to that marked E. There are five springs within the lock, four of which act upon the upper and lower tumblers, the other on the point-bolt H. M is the bottom part of the key. The dark ring in the center represents the hollow to be applied to the lock pin, B, above-mentioned."

To work the lock, it is necessary first "to place the head or bolts of the lock towards the left hand; then take the key with the right-hand, with the small pointer *A*, in the shank of the key towards the right: after this, put the key down to the bottom of the socket upon the center-pin *B* in the lock, and give one half-turn with the pointer in the shank of the key, upwards; by which the bolt *C*, at the top will be locked.

In the next place, draw back the key about one inch, so that the webs or bits of the key may clear the tumblers in the lock; then

turn the key with the small pointer towards the right hand, and put down the key in the manner above-mentioned. After this, make one-half-turn with the pointer in the shank of the key downwards, by which means the lower bolt *H* is locked, and the higher bolt *C*, unlocked.

Then draw up the key as aforesaid, and turn it with the pointer in the shank to the right hand. In the last place, thrust down the key, and give one half-turn with the pointer in the shank of the key, upwards, by which operation both the bolts, *C* and *H*, will be locked; so that, when the bolts are to be unlocked, the pointer in the key must be towards the left hand, and must be worked as above directed."

DAVIS'S LOCK, Patent dated April 11, 1799.

Davis's lock was made with a double chamber, and had wards on the sides of the keyhole. The key was inserted into the first chamber, and turned a quarter round. It was then pushed forward into the inner chamber, where there was a rotating plate, containing a series of small pins, or studs, which were laid hold of by the key.

By turning the key, the plate was moved round, the tumbler was raised, and the bolt shot backwards or forwards. This lock was now used to some extent on the cabinet dispatch boxes; but it was expensive, without affording any very great security.

A circumstance occurred some years ago (1815) which will serve to illustrate the amount of reliance which was then placed upon the security of Davis's lock. One of these locks, by some chance, was sent to Wolverhampton to have a key fitted to it, and was for that object given into the hands of a certain locksmith, who, on taking it to pieces, discovered an inscription inside the lock, stating that into whosoever hands that lock came to have a key or keys fitted, the individual, on application to Mr. Vansittart, the Chancellor of the Exchequer, should receive the sum of twenty guineas.

The amount was applied for, and was duly paid by the right honorable Gentleman, who also offered to the said locksmith a further sum of 100 Pounds if he would give up the name of the person who had sent him the lock. We can vouch for the correctness of this statement, having seen the original letter, dated 25th April, 1815, from Downing-street, which enclosed a bank post bill for the amount, and requesting a receipt for it.

On a similar occasion Mr. Davis posted from Windsor direct to Wolverhampton, to get possession of one of his locks.

There is another anecdote in connection with the inventor of this lock, which we cannot refrain from giving here. Mr. Davis was an inhabitant of Windsor, where he carried on his business as a lock manufacturer, and who was honored with the patronage of his late majesty, King George III, who paid the patentee frequent visits, and who also evidently took a great interest in his welfare.

On one occasion, when in his workshop, his majesty offered to confer on Mr. Davis the honor of knighthood, which Mr. Davis respectfully and humbly declined, saying to his majesty "Sire, it would sound very odd, were I to meet a gentleman in the street, and he were to say, Sir George Davis, please to come and mend my smoke-jack." We need not say that no further reason was required by his majesty, who seemed much pleased with so sensible and consistent a reply.

NORTON'S LOCK, invented about 1800.

In this lock, the key, instead of being adjusted to the main bolt, is gated to a wheel, and the wheel is gated to the bolt. There is also a tumbler, the stump of which works in a semi-circular slot cut in the wheel or disc. There is another slot cut in the wheel or disc from the circumference towards the center, through which is fixed a slide and setscrew, and by means of such slide and setscrew the bolt can be made to shoot out a longer or a shorter distance as the slide and setscrew is nearer to or further from the center of motion.

In ordinary locks, if it is desired to give the bolt a long throw, it is effected by the length of the key-bit, but in this lock, no matter whether the bolt is required to be shot out much or little, it can be done at pleasure by merely altering the position of the slide and setscrew.

HOLEMBURG'S LOCK, Patent dated June 24th, 1801.

This lock is simple in construction, its principal peculiarity being the circular bolt. Figure 149 is a front representation of the lock. *a* is a screw which secures the spring in its place on the lock-plate; *b* is an inside tumbler gated to a stump on the extremity of the orbicular bolt, *c; d* is the key-bit which works inside the orbicular bolt; *e* is a stud for stopping the return of the principal bolt; *f* is the quadra-circular conductor for the

principal bolt; and *g* is the catch which answers to the link-plate in other locks. A fastening for sashes, shutters, and doors, the patentee claimed, which is constructed on the same principle.

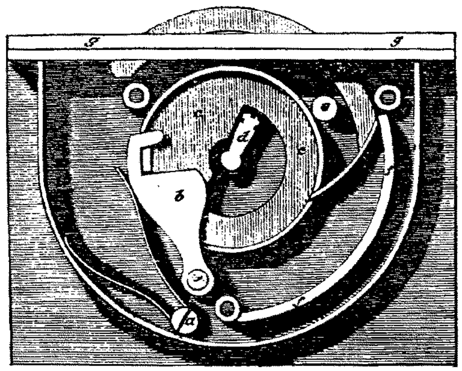

Figure 149. Holemburg's Lock

EAGLE's LOCK, invented about 1801.

The peculiarity of the construction of this lock consists in the employment of spring wards. The wards are produced in two separate parts, with the back part made to fall out of the true circle, towards the center or drill-pin; so that a key cut to correspond with the front wards in moving round would come in contact with and would be stopped by the end of the spring wards. The true key has the cuts of the bit made sufficiently wide to pass both the front and the back or spring wards, and is thus enabled to reach the tumbler and move the bolt. In all other respects it is a common tumbler lock.

DOODY's LOCK, invented about 1804.

This lock is constructed on the secret principle with wards. It is so made that the key will pass round either way without acting upon the tumbler and bolt. The back part of the ward is cut out in two places for the purpose of allowing the key, (by being drawn towards the keyhole), to pass through one of the openings when it comes in contact with the talon of the bolt, which is thus moved, and the key is then pushed through the other opening moved round, and withdrawn in the usual way. The wards of the key are cut to correspond with this "shifting" action. Two studs are fixed in the cap of the lock to prevent the key revolving, unless pushed in to the proper depth.

The inventor of this lock was favored by the authorities of

Stafford Gaol with the repairing of the locks connected with that establishment, and about the year 1812 he was unfortunately in pecuniary difficulties, and became an inmate of the gaol for debt.

By some means, he picked the locks placed between him and liberty, and made his escape, but finding he was likely to be punished if again caught, in the words of the narrator, "he went and picked himself in again." This is one of the many facts which might be brought forward to prove the inferiority and insecurity of the locks in use at that period.

STANSBURY's LOCK, Patent dated May 18th, 1805.

The inventor of this lock, an American, came over to this country in 1805, and patented it, “and was very assiduous in endeavoring to get it introduced; in which attempt, however, he met with so little encouragement, that it might be deemed a failure. Nevertheless, there was sufficient originality in his **contrivance(490)** to merit a notice in this place; the key was of the ordinary shape of those with a pipe, but longer and narrower in the bit, on the lower side of which were a number of pins projecting from its surface; the key had no wards, and the lock, consequently, none.

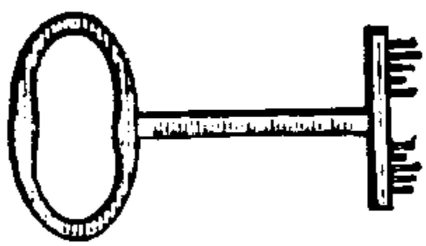

Figure 150. Key to STANSBURY’S LOCK

The bolt was not moved by the key immediately, but through the instrumentality of a revolving circular plate, attached to and underneath which was a fixed pin that took into a notch in the bolt. It was therefore the office of the key to remove the impediments to the motion of the revolving plate, which impediments consisted in a number of pins passing through it and another *fixed* circular plate or bridge underneath, the said pins being pressed through both and made flush with the surface of the upper plate by the action of springs riveted to the bridge.

The two plates thus locked together were separated by the projecting pins upon the key, which, entering the holes in the

upper plate, pressed the spring pins out of them and turned the plate round. The pinholes in the circular-plates were not opposite to the keyhole but on one side leading towards the bolt; so that, to find them out, it was necessary to push the key slightly against the plate whilst turning it round.

THOMPSON's LOCK, invented about 1805.

This lock is constructed with one single-acting tumbler combined with one double-acting tumbler, and is especially adapted for sliding doors, or such doors as are divided in the middle, and which at this period were generally in use. One bolt of the lock shoots into the door-frame, and the other bolt, which is hook-shaped, shoots into the lower part of the door. These locks in former years were very extensively used.

MACE'S LOCK, invented about 1807.

This lock is constructed on what is commonly called the “sun and planet" wheel, and the action is both easy and beautiful. There are double-acting tumblers, the stumps of which are gated into semi-circular slots in the wheel or disc for a long or short shoot of the bolt, as the case may be. The key passes into slots or openings cut in the tumblers, and so moves them into their proper position, moves the wheel, and shoots the bolt. The inventor of this lock was considered in his day one of the best and most ingenious locksmiths of Wolverhampton. His locks were well made and particularly strong.

COX’S LOCK, invented about 1808.

This lock was invented particularly for **fastening(491)** the glazed doors or sashes of rooms opening onto lawns. Many contrivances have been adopted for this purpose, both in this country and in France, but it is questionable whether any of them have surpassed this in effectiveness and simplicity of action. By the use of a rack and pinion, a bolt is shot at both the top and bottom of the one door at the same time as another bolt at right angles to the others is shot into the other door. The inventor of this lock was celebrated for the general quality of his other locks, viz., rim and mortise.

ROBERTS' LOCK, invented about 1809.

The peculiarity of the construction of this lock consists in the employment of a circular disc, which is placed on the drill-pin,

in which are two holes at certain distances from the center. On the bottom of the key-bit are two studs corresponding to the two holes in the disc. In using the lock, these studs enter the holes of the disc and move it round, which at the same time either lifts the tumbler or moves the bolt, whichever the maker of the lock may desire. The disc in this lock is the auxiliary which moves the bolt, and in this respect is similar to Bramah's design.

STUART'S LOCK, invented about 1810.

This lock is very ingeniously constructed, and is one of the many attempts that have been made to introduce into the construction of locks the tooth-wheel. The wheel or disc has cut into its circumference many notches, all of the same depth, except one, which is cut much deeper. There is also a double-acting lever, and a blade riveted on to the bolt, which blade works into the deep notch.

The action of the lock is as follows: the key is inserted and the bolt shot out in the usual way; the key is then lifted up against the cap and moved round six, seven, eight, or more times, until the requisite number of the shallow notches are passed and the true or deep notch or gating of the wheel is moved away as many notches as may be desired.

To open the lock, the exact number of times the key has to revolve before meeting with the deep or true notch of the wheel must be kept in mind, otherwise it would be a question of time how long it would take to open it. As a lock on the secret principle, perhaps it is second only in security to the letter-lock.

This lock would much puzzle a person to open even if he were possessed of the true key. The shallow notches on the disc correspond to the false notches which were subsequently introduced into the lever. The notches in the lever of Strutts lock are upon the same principle.

TOMPSON’S LOCK, Patent dated December 29th, 1808.

Tompson’s was a flush bolt lock, with two tumblers; one was gated to work the bolt up, then the key met another talon and tumbler placed at right angles to the first, and shot the bolt. This lock in its day had a good sale. Tompson was the first to *cast* the projections in flush-bolt and other locks, to save the time

and trouble occupied in fixing them in the manner previously adopted.

ALPORT's LOCK, invented about 1812.

The peculiarity of the construction of this lock consists in the introduction of moveable wards into chambered locks, that is, where there are one, two, or more platforms raised off the lock-plate, and with the keyholes set in various positions in the platforms. These locks are made to lock twice or thrice, as desired.

In using them, the key is inserted in the lock and pulled up towards the cap and passed round, which unlocks one shoot of the bolt; the key is next pressed down on the first platform, tried round to discover where the second keyhole is, and when found, the key is then passed through to perform the second operation of locking, and in the same way for the third or bottom tier, when the key comes in contact with wards that move with the key.

There are two clicks which the nose of the key has to pass, which press against these moveable wards; and should the key nose be too long, it lifts up the first click, which then falls down behind the key, so that it cannot be brought back again, and in passing further round meets with and is blocked against the nose of the second click, which forces a stud on the back of the first click into the main bolt, and prevents the lock from being opened. To shoot back the bolt, violence must be resorted to, the key being held fast in the lock. We may remark that the chambered lock is very ancient, and the inventor of it unknown.

DANIELL'S LOCK, invented about 1814.

Mr. Daniell's, a justly celebrated lock-maker, was one of the first, who in inventing an improved lock, abandoned the complicated constructions of those locks which had preceded it, and by taking the common tumbler and placing another stud upon it, made it a *double-acting* one, without materially augmenting the cost (say two-pence per lock).

It is to be regretted that he did not proceed with his simplifications, but most probably the time was not ripe for the introduction of such simple movements, as his next improvement, viz., the *security-bolt* for latches or spring locks for front doors, is not so simple in construction, but it is very excellent; in fact nothing to the present time has been invented

to supersede it.

Previous to the date of this latter invention, anything that could reach the bolt of spring door latches would easily shoot it back, but Daniell's added a secondary, bolt either above or below the main bolt, and the tumblers or levers being gated upon it, the bolt could not be easily tampered with until the security part of the lock was passed. The general quality of Daniell's locks in his day was second to none, and the locks at the present time, made by his successors are of a very superior quality.

GILES'S LOCK, invented about 1814.

Mr. Giles was the inventor of the padlock, in shape of a ring, and of various other similar forms. They were jointed in the ring part, and the lock was sometimes made as a slip upon the ring and frequently with a projecting barrel, through which the key was forced to reach a spring latch, or sometimes to turn a screw. These locks were remarkably cheap and very useful for all ordinary purposes.

MITCHELL AND LAWTON'S LOCK, Patent dated March 7, 1815.

This lock, invented by Mr. J. Lawton, is one of considerable merit. The principal peculiarity of its construction is the employment of a sliding steel curtain before the keyhole. Figure 151 "represents a six-inch dead lock with the cap removed. *A* is a circular steel curtain, with two keyholes pierced in it, connected with the curved aperture shown at *A*.

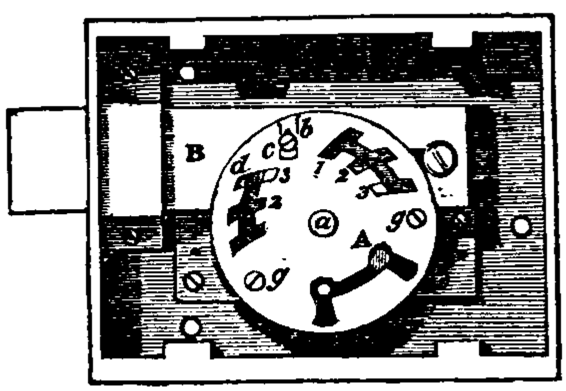

Figure 151.

The curtain *A* turns upon the center pin *a*, and is united to the bolt *B* by the screw *b*, which passes through the curtain, and

enters the stud *c*, to be described hereafter; the stud *c* moves in a slit shown in dotted lines at b; d e represent two stumps fixed to and being part of two tumblers which are placed below the curtain A; these stumps drop into the racks or notches made to receive them in the curtain 1 2 3, 1 2 3, and while there, prevent the bolt A from moving either way.

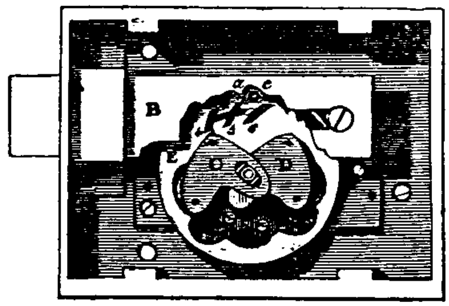

Figure 152.

The action of this part is similar to Barron's principle; but in this lock the motion of the parts is compound; for while the bolt B moves in a straight line, the curtain A turns at the same time upon the center-pin a, and consequently it moves in a circular direction.

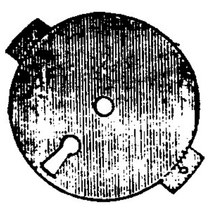

Figure 153.

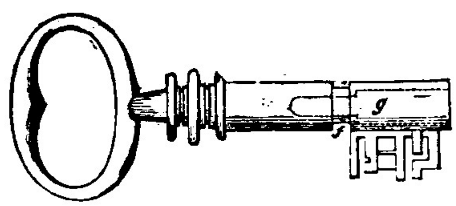

Figure 154.

Figure 155

Figure 154 represents a key; *f* shows a groove formed in the cylindrical part to admit a portion of the steel curtain to enter and move therein, while the key is employed in moving the bolt either backwards or forwards, as occasion may require.

Figure 155 represents the key-pin of the lock detached, so as to give a correct idea of its form, which exactly corresponds with the hole drilled in the key shown in dotted lines at g, figure 154.

Figure 152 represents a lock with the steel curtain removed, so as to show the position of two of the tumblers *C,D*, the stumps of which enter the notches of the curtain, and keep it stationary.

The circular plate *E* has a rack or set of notches *4, 5, 6,* in which a third tumbler acts similar to those that have been described. *c* shows the position of a strong stud, fixed in the circular plate *E*, which comes through a slit formed in the bolt. This stud is tapped to receive a screw, which unites the curtain to the bolt *B* and circular plate *E*. See *b*, in figure 151. Figure 153 shows the cap of the lock detached.

SCOTT's LOCK, invented about 1815.

The peculiarity of the construction of this lock consists of one of the most elegant and simple movements ever introduced, viz., a pair of tumblers gated into two circular discs or wheels. The security of this lock is equal to Barron's.

Figure 156 represents this lock as it appears on the base of *Aubin's Lock Trophy. A* is the bolt; *B* the tumblers; *c c* the two discs; *D D* the studs of the tumblers in their true position in the lower disc. The action is as follows: when the tumblers are lifted to their true positions, the discs revolve, and the studs in the tumblers appear stationary, but when the bolt is shot back, they fall into their original positions in the wheels or discs.

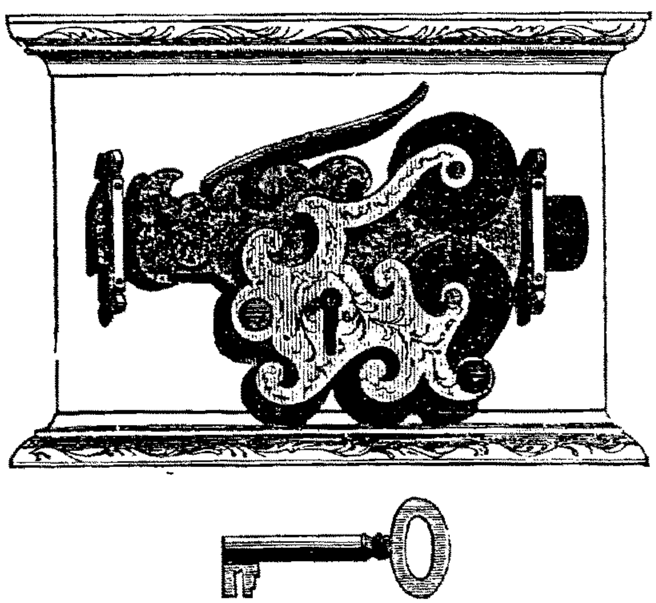

Figure 156. Scott's Lock

We regret that this is the only invention bequeathed by Mr. Scott

to posterity, as he evidently understood the beauty and desirableness of simplicity. This is nearly the last simple movement we have to chronicle, as in most of the other locks we have yet to describe a complicated construction prevails.

DEANE'S LOCK, invented about 1815.

The peculiarity of this invention consisted in combining a Bramah with a Barron lock, the Barron at the front, the Bramah, at the back. The security was of course increased, but at the expense of adding considerably both to the complexity of the lock and the cost of making.

SOMERFORD'S FIRST LOCK, invented about 1815.

The peculiarity of this lock consisted in its being constructed with one double-acting draw-tumbler, which is the reverse of the principle of Barron's lock.

RUXTON's LOCK, Patent dated May 14, 1816.

This is unquestionably the most meritorious lock invented to this period (1816) since that of Bramah's, and is essentially a *detector* lock, and the first of its kind.

Figure 157 represents a drawer or till lock, with the cap removed to show the works. Location *2* is the drill-pin; *3 3* is a ward. The two parallel lines below *2*, and apparently connecting the ends of this ward *3 3*, are two other wards.

The key passes these wards, having apertures or cuts (technically called the wards of the key) for this purpose in its bit. These wards are riveted to the plate of the lock. *A A A A* are the screw holes, through which the screws are put that fasten the lock to the drawer. *B* is the bolt, which has a cap or metal cover, being a plate that is screwed on by the screw a. *c* is a steel fence, to guard against the effects of any instrument that might be introduced at the keyhole. Figure 158 represents the inside of the lock when the cap of the bolt is removed.

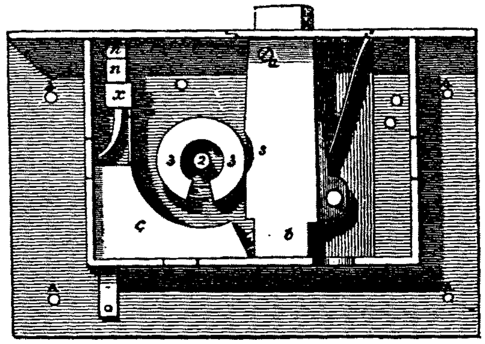

Figure 157. Ruxton's Lock

This cap in figure 157 conceals from view what here appears. *c* is the lever turning on a pivot *a,* and acted on by the spring *2 2*. *B B* is the bolt, the motion of which, up or down, is not hindered by the pivot *a*, nor by the spring *2 2*. *a* is the hole into which the screw goes that screws the cap of the bolt. This screw is seen in figure 157 where likewise the cap of the bolt is seen.

The pivot *a* (figure 158) projects from and is fastened to the lock-plate. The upper end of the spring *2 2* is also fastened to the main bolt. The bolt *B B* can move up and down. Its upper part moves through the selvage, and its bottom moves through the lower part of the rim. In figure 158 the bolt is locked out.

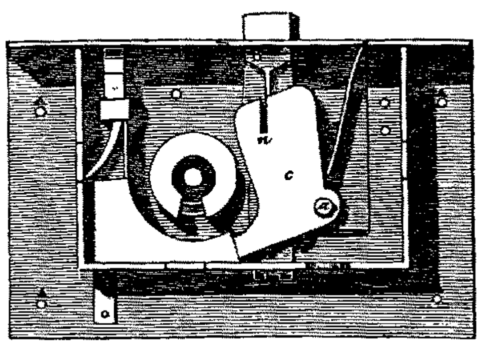

Figure 158. Ruxton's Lock

In the lever *c* is a slit *n*, and unless this slit be placed under the blade *r*, which is a part of the bolt, the bolt cannot descend. Figure 159 shows the position of the bolt after the operation of unlocking has been performed; and here the blade of the bolt appears in the slit of the lever.

It must be observed that there are three levers, and that the

slit in each is differently situated, and that the tails of the levers are of unequal lengths. The tails of the three levers, when in the locks, are concealed from view by the steel fence *c*, figure 157. The three levers being on their pivot are acted on by the springs *2 2*, figure 158, or rather each of them is acted on by one of the three tails which the extremity of *2 2* forms.

The edges of the three levers, when on their pivot, and when the operation of locking has been performed, present an even smooth surface perpendicular to the main-plate of the lock for the key to act on in its progress through the lock. Each lever yields to a moderate pressure and may be moved by such pressure far beyond its limit. On removing the pressure, it regains its former position.

The patentee states that for greater security he sometimes makes the steel fence *c* (figure 157) extend round as far as the bolt *B*. These levers admit of six permutations; four should admit of 24; five of 120; seven of 5,040; and eight of 40,320. The maker, therefore, has it in his power to increase the means of security to any extent at pleasure. Such is Ruxton's lock in its simplest form, but it was also constructed with the addition of a *detector.* As before stated, the fence *c* (figure 157) conceals from view the tails of the levers, but in figure 160 the tail of one of them appears.

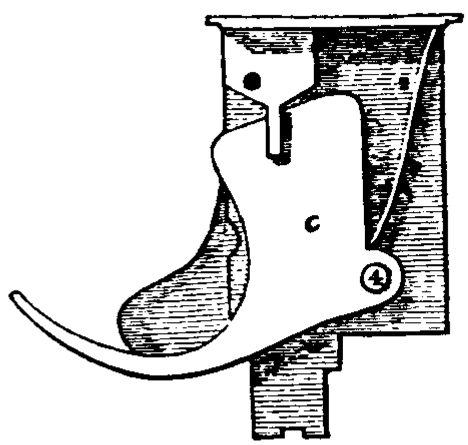

Figure 159. Ruxton's Lever

The ends *d* of all the tails come close to a small and thin plate of metal, which the patentee calls the prop, *1*, (*figure* 160). The outer edges of the tails touch the cheek *4 5* (figure 160). The prop has two pivots, and one part of it is lower than the other.

The prop, though it turns on pivots, cannot turn *towards* the tail *d* of the levers further than to be perpendicular to the main-plate of the lock, but it can turn from the levers so far as to be flat against the main-plate, with its edge, *1*, removed from the levers. To prevent the prop turning too far towards the levers, the spring *a b* that presses on it has a *shoulder,* against which shoulder the prop rests.

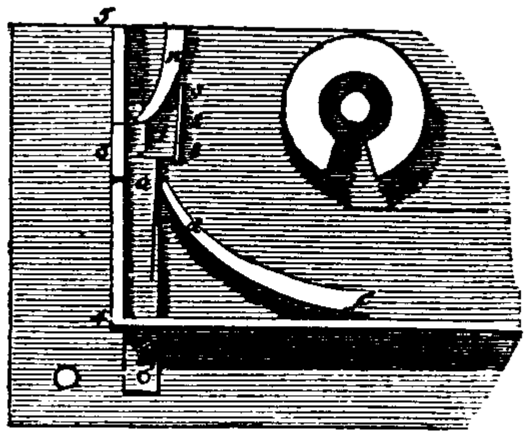

Figure 160. Ruxton's Detecting-bar

At location n, figure 160, is the lower termination of the detecting-bar, the only support for which is the spring a b. In figure 157, the whole of this detecting-bar is seen; it is there marked with the letters n n, and it moves in a piece of metal, x, riveted to the main plate of the lock.

A portion of the upper part of the detecting-bar is larger than the rest of it, in order to prevent its passing down too far through x, and likewise to prevent its passing too high its upper end is, except when violation is attempted, on a line and even with the selvage of the main-plate of the lock, as represented in figure 161. Location w (figure 161) marks the spot occupied (except when there is an attempt to violate) by the upper end of the detecting-bar.

Figure 161.

An attempt at violation is to be supposed to have occurred, and

such an attempt would cause the detecting-bar to fall as far as *x* (figure 157) would permit it. If the prop 1, (figure 160) should be pushed or stirred by the tails *d* of the levers, or by any one or more of them, it must turn so as to lie flat against the main-plate of the lock.

The spring *ab* must press upon, that is, lie flat upon the prop, and the detecting-bar, losing its only support, must fall down. The lock being screwed on to the front of a drawer, the detecting-bar is perpendicular to the plate of the horizon, and therefore, losing its support, it must fall.

It has been mentioned before that the tails of the levers were of different lengths. They are so placed, and the prop *1* (figure 160) is so placed, as that if the tail of either of the levers should move in the slightest degree beyond their true position, the prop would be pressed upward, the spring *a b* would press it so as to make it lie closely to the main-lathe of the lock, and the support of the spring which would have followed the prop would fall, leaving to the view of the proprietor the lock, when he should next open his drawer, a hole in the upper part or selvage of the lock, as in figure 161, which hole, had there been an attempt at violation, would be filled to a level with the surface of the selvage with the detecting-bar.

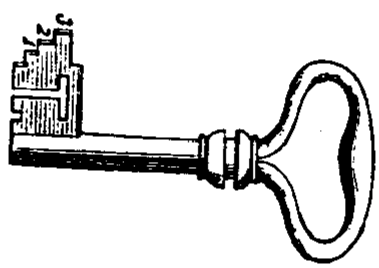

Figure 162. Ruxton's Key

In the specification the patentee names other modes of employing this detecting apparatus. In order to facilitate the readjustment of the detecting apparatus, after an attempt to violate, a part of the main-plate of the lock is sometimes made moveable, up and down, in grooves; which moveable part, when withdrawn, brings with it the detecting-bar, the prop, and the lever, if there be a lever.

The simplicity of the lock is not affected by this apparatus for betraying clandestine efforts to open it, the operations of locking and unlocking being quite independent of such apparatus,

and therefore the lock may be considered to be independent of it.

The patentee further states that, in order to deter from any attempt at violation, he sometimes constructs the lock so as that such an attempt must produce an alarming noise, which may be effected in various ways. Also, that an attempt to violate it causes to be exhibited all indication that such an attempt was made to every person who may chance to look at the thing secured, as, for instance, a drawer.

This is effected by the disengagement of the spring *a b* (figure 160) letting fall a bar within the lock, the end of which bar is, until an attempt to violate be made, on a level with the outer surface of the front of the drawer, but, falling, a cavity appears in the front of the drawer.

Another mode of adapting the principle of a detecting apparatus is (where local situation does not forbid) to construct the lock so as that the person making the attempt will, without sustaining personal injury, be caught in the act; but the particular mode of effecting it the patentee thought it better not to publish.

The patentee states also that he sometimes constructed this lock so that an attempt to violate it must cause the false instrument used in the attempt to be detained; but then such an effect is produced that the lock becomes unopenable by any means, even by its legitimate key, all recourse must then be had to the sledgehammer, the saw, the drill, or the chisel.

He further states that he sometimes so constructs the key so as that, if lost or carelessly kept, a person finding or procuring it shall not be able to perform the operation of unlocking. This object is attained thus; in some spot of the nose of the key, from which should issue no projection, a mock projection is affixed, so contrived as to be removable in a moment, and without trouble.

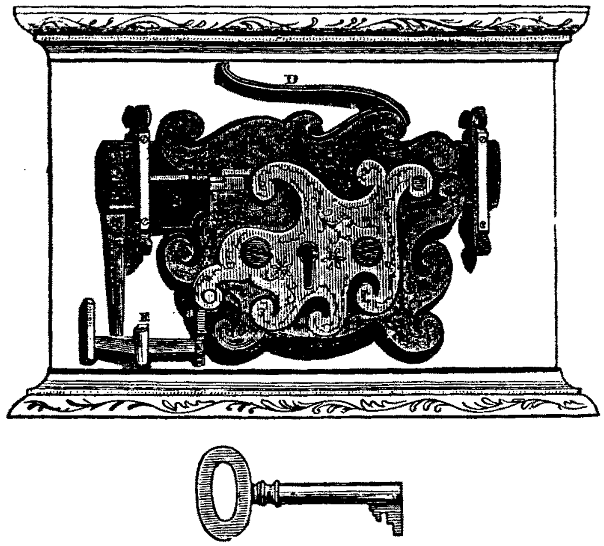

Figure 163.-Ruxton's Tell-tale Lock.

KEMP'S LOCK. Patent dated May 27, 1816.

The security of this lock consisted in the adaptation of tumblers or sliders, operated upon by two, three, or more small concentric tubes of different lengths, placed inside the barrel of the key. These tubes were made of such a length as to push back the pins or sliders that detain the bolt to the required positions, until each one corresponds with the notch that is cut in it for the projecting part of the bolt.

Mr. Kemp calls his invention the union lock, from the circumstance that it unites the qualities of Barron's and Bramah's locks; and from the manner in which the combination is effected. It affords, according to the inventor, a greater degree of security than either of the former, or than both of them together, supposing a lock of each kind was placed on the same door; and that a dishonest servant, who does not possess any particular ingenuity, may be instructed by a locksmith how to take the requisite impressions of either Barron's or Bramah's keys, even if he could be entrusted with them only for a few minutes.

This cannot be done with the key of the union lock, as it would require the locksmith to examine it himself, and to make several tools to ascertain its different dimensions, which he could not do without having it in his possession for some considerable time, with leisure to make repeated trials.

In this remark of Mr. Kemp's we entirely coincide; and it applies to all locks hitherto made (1834), that the *keys,* when in the possession of a workman, *may be copied;* and, in many, without possession. Mr. Kemp's invention may supply a partial remedy for this defect; but until a complete one is provided the art of lock making is imperfect, and no locks are inviolable.

Viewing the subject in this light, it affords the editor of this work (Hebert's Encyclopaedia) much satisfaction to state that he has in his possession a lock, the key of which *cannot be copied;* a locksmith possessing no tools by which an exactly similar one can be made; and the machine by which the original one was made is so arranged as to be deprived of the power of producing another like it.

The lock is very simple, very strong, and can be very cheaply made. The cost of a complete machine to make them would be about one hundred pounds; with that they might be manufactured at one-half the expense of any patent lock. The inventor is desirous to have the subject brought before the public under a patent, but want of time to devote himself to such an object at present obliges him to lay it aside.

The machine here referred to has not to the present time (1856) been patented, and therefore nothing is known of its particular construction; but that such a machine is capable of being constructed to do all that has been stated we verily believe. Further, we believe that such a machine may even be made self-acting. If the attention of the Lancashire machinists were to be given to the manufacture of locks and keys, a perfect revolution in the trade would be the result.

SOMERFORD'S SECOND LOCK, invented about 1816.

This lock is constructed with a lever and two tumblers, but with the tumblers so arranged that one is made to ascend, and the other to *descend,* before the bolt can be shot. The lower ascending tumbler has an iron plate attached to it, the use of which, besides receiving the key and thus bringing it down to its central place, is, that it stands as a complete guard in front of the riding tumbler which descends. The lever on the top of the bolt is also a new construction, having the tumblers working in its racks, and refusing to let them pass until it is brought to its proper position; on which account the inventor calls it the *master lever.*

Figure 164 is a front view of a door lock, with the cap or upper plate removed; *a a* is the bolt, having a longitudinal perforation in each side of which are four notches opposite each other; *b b* is a plate of brass fixed to the bolt by the pin and collet *c*, under which it freely moves. This plate has a perforation, with four notches in the upper side, and three in lower, corresponding with the notches in the bolt, but deeper.

d d is a spring fixed to the top of the bolt acting on the protuberance *b* of the master lever *b b*, and pressing it on one side, so as to prevent the notched perforation corresponding with that of the bolt.

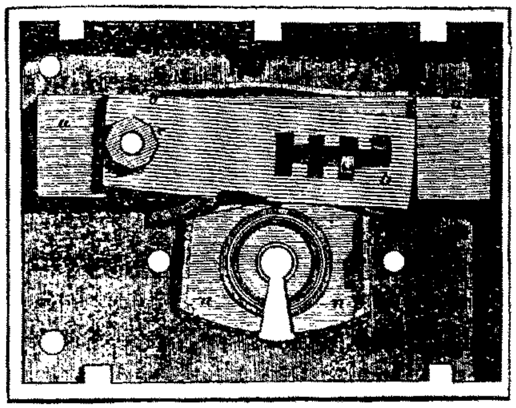

Figure 164. Somerford's Lock

Under the bolt are two tumblers, one standing before the other, both working on a center pin fixed in the bolt under the lever at the letter of reference *c*, and their stumps working in the slots and gatings of the bolt and master lever. By the aid of a double spring acting on the tails of the tumblers, the stump of one tumbler is kept in one of the upper notches of the bolt, while the stump of the other tumbler is kept in one of the lower notches. While in these positions, the bolt is kept from moving backwards or forwards. Therefore, to move the bolt, the key (figure 165) must by its hook *l*, traveling in the groove of the under tumbler *f*, pull the stump just out of the upper notch, and no more, while the front of the key, pushing the second tumbler, moves its stump just out of the bottom notch, and no more.

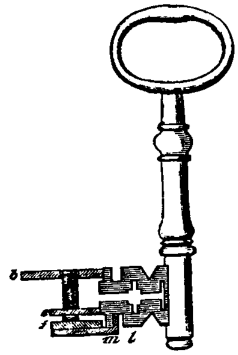

Figure 165. Somerford's Key

Now the stumps being even, the bolt is free of them, but is locked by its upper plate, or master lever *bb,* catching them in two of its upper notches; therefore the upper front of the key must raise this master lever to make its perforation or gating coincide exactly with that in the bolt.

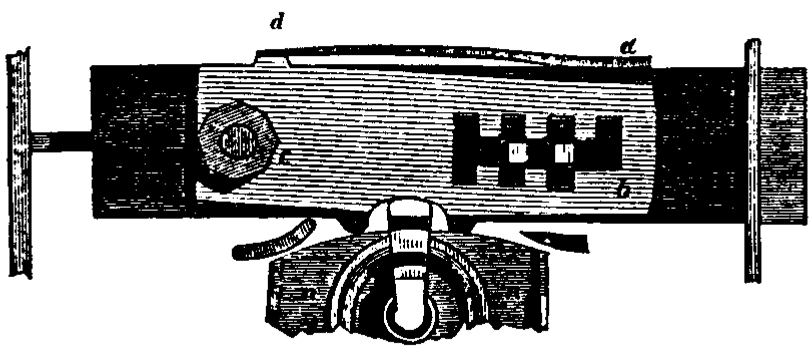

Figure 166.

Then it is quite free, as in figure 166, where the key is in its place, moving the bolt. Figure 167 shows the bolt advanced, the key just left it, when one stump rises into the upper notch, and the other sinks into the lower notch of the bolt, and the main lever, *bb,* falls with one of its notches on the upper stump, by which the bolt has three securities, and these are divided by the plate *n n,* or bridge-ward, which passes through the middle of the key, two being below and one above.

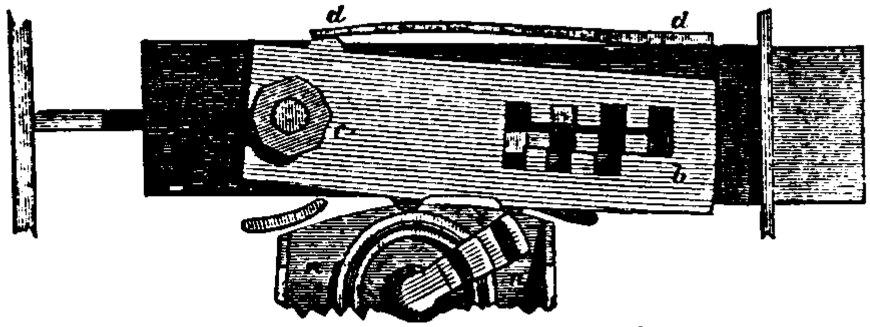

Figure 167.

BURTON'S LOCK, invented about 1816.

The improvements introduced by Burton were in locks for doors made in two parts and for sliding doors, and consisted in making the bolt-head hollow for the purpose of containing the tumbler, and which is the full length of the bolt. On the end of the tumbler there is a hook, so that when the bolt is shot out, the tumbler being attached to the bolt and projecting from the hollow bolt-head fastened onto the lower part of the door; or if sliding doors, then the tumbler hooked behind a plate fixed to the one door and so secured both. There is a stud in the lock-plate for the tumbler to catch and hold on.

DUCE'S (SENIOR) LOCK, invented about 1816.

This is a very simply constructed lock. Its peculiarity consists of a plain bit of iron, which forms both the bolt and a double-acting tumbler. The lock is nearly as secure as Barron's, and can be produced at a lower price than any other lock that is equally secure that we know of.

The action is as follows: the piece of plain iron that forms the bolt and tumbler is gated through a cheek or other projection of the lock-plate. in such projecting piece is cut a slot for the bolt to move through, and a corresponding slot in the bolt; the bolt has either an up or down motion from the key. A light steel spring being riveted to the bolt or the lock-plate, forces the bolt either up or down; and this forms the combination against the cheek or other projection of the lock-plate.

We should recommend the locksmiths of the present day to take this specimen of simple but effective mechanism and count the few limbs it contains. This lock appears to be almost unknown, and it is not improbable that the absence of complexity in the

construction, and want of show in its appearance, were sufficient objections at that period to prevent its being more generally used.

The principle of this lock is similar to the principle upon which the *modern* medical man acts, and the dissatisfaction expressed by the purchaser of the lock and the patient of the doctor is equally the same. In the first case the buyer exclaims with astonishment, "Why there is nothing in it;" in the other case the patient exclaims when he receives his bill." By the powers! I have had nothing for my money."

Many persons in the one case think that to make a lock secure it must necessarily be *complicated;* in the other case they as certainly believe, that if the doctor is to do them any good, he must send them *plenty* of physic; and in both theses cases, when such a principle is carried out, they are fully satisfied of having had "value received" for their cash.

TOY'S IMPROVEMENTS, introduced about 1816.

It is to Toy that the merit is due for improving stock or wood locks, by the introduction of solid brass wards of peculiar and various designs, and also combining the common tumbler with a lever, and working both from one center of motion, thereby adding materially to the security of the lock, with but little addition to the cost of manufacture. He also introduced barrels of a peculiar form, which worked in the keyholes; and some of the latter had the drill-pin fixed in them.

All wooden locks are called stock-locks, from the circumstance of the mechanism being embedded in a piece of wood, the same as the gun-barrel; the locks are embedded in their wooden stock.

There is another lock of this description, called the "Banbury lock," in which the various limbs composing it are fixed separately in the piece of wood hollowed out for the purpose; whereas in the former the lock is first made complete on its plate, which is then inserted in the cavity of the stock prepared for its reception.

The Banbury locksmiths are in the trade called "wooden jewelers", but from what cause history doth not inform us.

HIGGINSON'S LOCK, Patent dated February 1, 1817.

This invention consists in the adoption of a cylindrical roller in a particular and novel manner attached so as to prevent the introduction of pick-locks for opening works.

Figure 168 is the representation of the external part of a cylindrical box, to be attached to or upon the cap-plate. The keyhole of the cylindrical box is reversed to that of the cap.

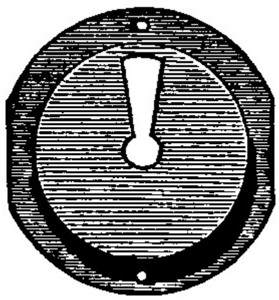

Figure 168.

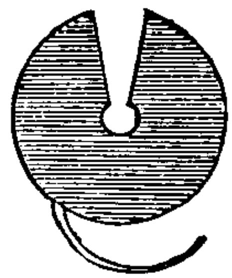

Figure 169.

Figure 169 is a roller, to be placed within the cylindrical box, with a slight spring only for the purpose of tightening it within the box. The object of this roller, which revolves (by turning the key) is to cover the keyhole from the introduction of a pick-lock; for when the key is out of the lock, this roller prevents all communication with the keyhole, and consequently with the interior; until by its revolution the aperture for the key to pass is brought opposite to the keyhole of the cap-plate.

Another mode which the inventor claims for the purpose of preventing the possibility of picking the lock is described in figure 170, and consists, first, of a cylindrical piece, *a*, sliding upon the circular ward, and closing or preventing all access to the works from the center. It has an aperture for the introduction of the key, by which the cylindrical piece is carried round, and upon withdrawing the key the aperture remains opposite to the hole of the cap-plate, or by the adoption of a revolving cross, fitting to and acting within the wards, so as to exclude all passage to the inner works.

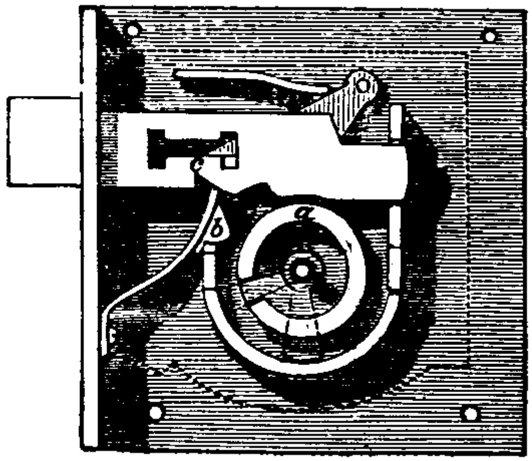

Figure 170.-Higginson's Lock

To preclude the introduction of a pick-lock through the outer channel of the wards, a projecting piece is placed marked *b*, bearing against the circular ward, and supported by a spring lever to admit the passage of the key. This piece *b*, if *attempted* to be raised by a pick-lock, or any other force, would recede into the notch *c*, and prevent the bolt from returning. In the alternative, instead of attaching this projecting piece to a spring, it may be suspended, against which a spring acts for the same purpose as the former, and by its receding into the notch, as before described, locks or confines the bolt.

***GOULD'S LOCK,* invented about 1817.**

Gould was the inventor of the lock with a *sliding* talon, i.e., the back talon or gating of the bolt is filed off, and a slide attached thereto which crosses the bolt, and is forced down by a spring at the back. On to the slide is riveted a spring with a stud upon it, and which holds to the main bolt. There is also a piece or bib which projects from the spring, which the key acts upon when required.

The locks were constructed with two or three levers, and sometimes with a common tumbler. The talon is the secret; for after locking the bolt out, the key is turned round again quietly to catch the bib and force the talon up, so that any key would pass by without moving the bolt. To bring the talon down again the key is used the reverse way.

Figure 171. Barron's Fly-talon

This is the second invention of a moveable talon. The first is that of Barron's, which was introduced soon after his patented lock, and was called the "fly-talon," as shown in figure 171.

LEES' LOCK, invented about 1817.

Lees' invention consisted of a peculiarly constructed *escutcheon* or *blind* for the keyhole of trunk locks, and although keyholes were in the locks, yet no keys were required to lock and unlock them. There were studs which had to be forced down in various positions, or sometimes these studs had to be pulled up to release the bolt. The escutcheon or blind was either lifted up or turned part way round, whichever was necessary to move the obstruction to the passage of the bolt.

BRUETON'S IMPROVEMENTS, introduced about 1817

The late Mr. Thomas Brueton, of Bilston, whose father and grandfather were dog-collar lock makers, introduced various improvements into these useful little locks. Some he constructed on the secret principle, others had two drill-pins, whilst some had fluted keys corresponding keyholes.

We have been presented with an assortment of these curious locks, selected from a stock left by Mr. Bureton, and now in the possession of his successor in the business, Mr. John Harper, jr., of Willenhall. We are indebted to this gentleman for several other specimens of locks and much interesting information, which we shall make use of in the course of the work.

CHUBB'S ORIGINAL LOCK, Patent dated February 3, 1818.

The patentee in his specification states:

"My improvements in the construction of locks are applicable

to all such locks as contain tumblers, sliders, or detents, for the purpose of detaining the bolt of the lock and preventing all motion, or withdrawing it, unless such tumblers, sliders or detents are first disengaged from the bolt. They also render these locks more secure, and likewise give **notice(492)** to the owner if any attempt has been made with a false key, or otherwise to violate the lock."

After describing the various kinds of locks then in use he states, "I do not make claim to the invention of any such lock as aforesaid, or to any particular combination of its parts, but my invention consists in the following improvements thereupon."

"First, in what I call detecting mechanism, of which the parts are as follow: the detector is a detent or lever, moving upon a fixed center-pin, and formed with a hook or catch, adapted to interlock with a notch or stud in the bolt of the lock, so as effectively to stop and resist the motion of such bolt whenever the detector is moved on its centerpin, so as to come into contact with the bolt. But if the detector is moved on its center-pin, so as to be clear of the bolt, it will then make no opposition to its motion.

The detector spring is a spring applied to the detector in such a manner as to urge its hook or catch towards the bolt when the detector is moved, or as to bring the said hook or catch nearer to the bolt than a certain position, which may be called the point of detection. The said detector spring will urge the detector hook away from the bolt whenever the same is at a greater distance from the bolt than the said point of detection.

The detector is so placed as to be operated upon by the tumblers of the lock when the whole or any of them are raised; and if any one of the tumblers is raised too high, that is to say, is moved further from the center of motion of the key than the required position in which the notch in such tumbler comes opposite to the stud of the bolt, as before described; then such tumbler, which has been too much raised, will move the detector beyond or within the point of detection.

In which case the detector spring will throw the hook of the detector into contact with the bolt, and the detector effectively stop any motion of the bolt, even though the tumbler, which occasioned the detection, should be restored to its proper position. Even though any one of the tumblers which may be raised too high will operate against the detector to throw its hook into

the bolt, yet there is no connection between such tumbler and the detector.

This can occasion the detector to leave its then position, as the true key of the lock will raise each tumbler to its required position, and no farther: it will never throw the detector beyond or within the point of detection, consequently the detector-spring will always keep the detector hook disengaged from the bolt.

If a false key or pick-lock be employed to raise the tumblers, there will be every probability that some one will be raised too high, and will move the detector beyond the point of detection, so that the detector-spring will then throw the hook into contact with the bolt. In this state, the lock is what I call detected, and the possessor of the true key has evidence that an attempt has been made to violate the lock, because the said true key will not now open it, for neither the true key or tumblers have, any means of communication with the detector after it has passed within the point of detection.

The remaining parts of my detecting mechanism are for the purpose of regulating the lock, or releasing its bolt from the detector; they are as follow: the regulating bolt is a bolt or slider within the bolt, adapted to operate upon the detector in such a manner as to raise or remove the hook thereof away from the bolt of the lock beyond the point of detection, and is operated upon by an adjusting instrument, which I call the regulating key, which may be similar in form to other keys, but will not open the lock, it being designed only to discharge the detector and restore the lock to such a state of adjustment that its own key will open it. For this purpose it has a different arrangement of the steps on its bit, one of which shifts or moves the regulating bolt.

The regulating bolt may be placed over or under the bolt of the lock, and has a pin or stud which projects from it, and applies against the same, or other tumblers, which are adapted to resist the motion of this regulating bolt, unless each one of the said tumblers are raised or moved into a given position, and neither more or less, by means of the several steps in the bits of the regulating key.

The regulating key being applied in its place in the lock, and turned partly round, its several steps will first raise each tumbler to its exact required position, and then it will move the

regulating bolt, by which means the detector will be moved without or beyond the point of detection, and the detector-spring will throw the hook of the detector out of the reach of the bolt, which may be effected by a small inclined plane, or wedge, upon the regulating bolt.

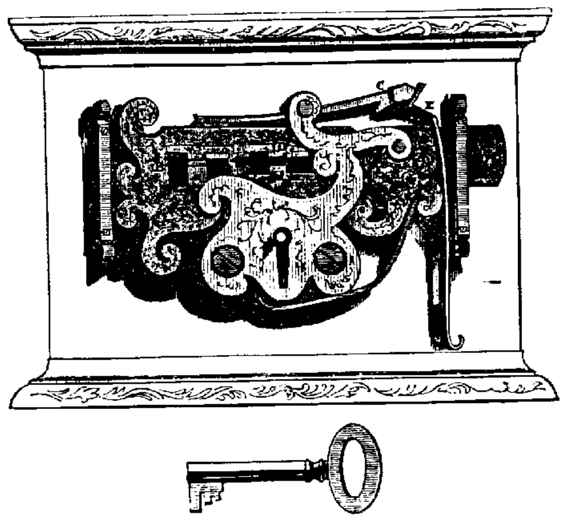

Figure 172. Chubb's Original Detector Lock

By this means the lock will be regulated or restored to its original state, and can be opened by its true key. Figure 172 represents a lock from Aubin's Lock Trophy, made according to this first patent. A is the bolt; B are the levers, or, as called in the specification, tumblers; c is the detector; D is the regulating bolt; E is the detector-spring.

There is an important difference between the original lock and all Chubb's other locks in the action of the "detecting mechanism." In the original lock the detector was released by a separate key acting on the regulating bolt, which left the main bolt unmoved; while in the others, in order to release the detector, the bolt has to be shot further out. This necessitates great care in the fixing of these locks, for unless sufficient play is allowed in the bolt-hole for the extra shoot of the bolt when the lock has been detected, the main bolt remains fixed in its detected position, and cannot be moved, and consequently the lock cannot be opened.

It is therefore necessary to allow from one-eighth to one-quarter of an inch, according to the size of the lock, in the depth of the bolt-hole, to allow for this second shoot of the bolt, in releasing the detector.

We may here remark on the subject of detectors in general, that we do not attach that importance to them that many do. The ready manner of releasing the detector lessens considerably its value as an indicator of the lock having been tampered with, for on attempting to unlock the lock with its proper key, the hindrance would in most cases be thought to be accidental, or arising from some misplacement, and in a moment, without consideration or reflection, the key would be reversed and the idea never occur that the detector had been thrown at all.

"The detector, although possessing some advantages is not without its evils, especially in locks where it is liable to be thrown by the tumbler being very slightly overlifted. In this case, the pressure commencing almost immediately upon the tumbler being raised to its proper elevation for allowing the bolt to pass, may indicate to the lock-picker the character of instrument to be used; and in such locks, when by long use the tumbler springs are considerably weakened, the detector may sometimes be started by a sharp movement of the proper key. Where there exists the remotest possibility of this occurring, the contrivance were far better absent, as the discovery of a detector being thrown is one of grave importance."

The editor of Hebert's Encyclopaedia, in his remarks on this subject, says "In Barron's and Bramah's locks, the picker has no means of knowing whether the tumblers are lifted too high or not; but in Chubb's he has only to put the detector hors de combat in the first instance, by a correct thrust from the outside of the door (which might be accurately measured), so as to fix it fast in its place; the detector then becomes a stopper to the undue ascent of the tumblers, and the extent of their range is thereby correctly ascertained; thus it appears to us the detector might be converted into a director of the means of opening the lock."

Our *greatest* objection to the use of detectors is, that these locks frequently, from various causes, detect themselves, and the mischief which may be caused in an establishment under such circumstances is most distressing to contemplate. The detector is thrown, and the proprietor at once jumps to the conclusion that some one of those who had access to the apartment or depository has been tampering with the lock.

Figure 173 represents Chubb's Lock as it was constructed at the time of the Great Exhibition of 1851. Having described the original invention, we shall here insert a description of this

lock from Mr. John Chubb's paper "On the Construction of Locks and Keys," read before the Institution of Civil Engineers in 1850, and which he afterwards published. We are indebted to Mr. John Chubb for a copy of this interesting paper.

Mr. Chubb stated that the lock bad been "improved upon by the successive patents of Charles Chubb, in 1824; by Charles Chubb and Ebenezer Hunter, in 1833; by John Chubb, in 1846; and by John Chubb and Ebenezer Hunter, in 1847." The last-patented lock, which, while retaining the peculiarities of the former inventions, has received such modifications and improvements as were, in practice, found to be necessary.

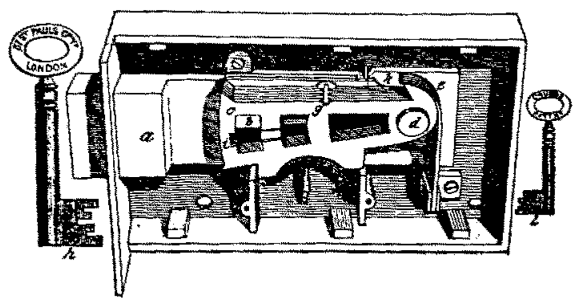

Figure 173. Chubb's Lock of 1851

It may here be stated, in order to render the drawing more intelligible, that Chubb's lock consists of six separate and distinct double-acting levers, with the addition of a detector, by which any attempt to pick or open the lock by a false key is immediately notified on the next application of own key. The detector is the great and peculiar feature by which Chubb's lock is so well known.

In figure 173, "*a* is the bolt, *b* the square stud riveted into and forming part of the bolt; *c* are the levers, six in number, moving on the center pin *d*, placed one over the other, but perfectly separate and distinct, so as to allow all of them to be elevated to different heights. *e* is a dividing spring, forming six separate springs, pressing upon the ends of the six levers. *f* is the detector-spring. It will be observed that the bottom lever has a tooth near the detector-spring. *g* is a stud or pin, fixed into and forming part of the bottom lever, and *h* is the key.

Now it will be obvious that the whole of the levers must be lifted precisely to the different heights required, to allow the square stud *b* to pass through the longitudinal slots of the levers, so that the bolt may be withdrawn. There is no means of

telling when any one lever is lifted too high, or not high enough, much less can the combination of the six be ascertained.

If a false key should be inserted, and any one of the levers should be raised beyond its proper position, the detector-spring *f* will catch the bottom lever *c*, and retain it, so as to prevent the bolt from passing; and thus, upon the next application of the true key, immediate notice will be given of an attempt having been made to pick the lock, as the true key will not then at once unlock it.

By turning the key, however, the reverse way as in locking, the levers will be brought to their proper bearing, allowing the bolt to move forward, and the stud *b* to enter into the notches *i.* The beveled part of the bolt *a* will then lift up the detector-spring *f,* and allow the bottom lever *c* to fall into its place. The lock being now restored to its original position may be opened and shut in the ordinary manner. It will be seen that when the lock is detected, nothing but its own key can restore it to its former condition.

The following **calculation(493)** will show the number of changes that may be made in the combinations of Chubb's locks. The same principle will, of course, apply to any other locks having a number of moveable levers, tumblers, or sliders.

The number of changes which may be effected on the keys of a three-inch drawer lock *1*, is *1* by *2* by *3* by *4* by *5* by *6 = 720*, the number of different combinations which may be made on the six steps of unequal lengths, as in figure 173, without altering the length of either step. The height of the shortest step is, however, capable of being reduced twenty times, and each time of being reduced, the *720* combinations may be repeated; therefore *720* by *20 = 14,400* changes.

The same process, after reducing the shortest step as much as possible, may be gone through with each of the other five steps; therefore *14,400* by *6 = 86,400,* which is the number of changes that can be produced on the six steps. If, however, the seventh step, which throws the bolt, be taken into account, the reduction of it only ten times would give *86,400* by *10 = 864,000* as the number of changes on locks, with the keys all of one size.

Moreover, the drill-pins of the locks and the pipes of the keys may be easily made of three different sizes, and the number of changes will then be *864,000* by *3 = 2,592,000*, as the whole

series of changes which may be gone through with this key.

In smaller keys, the steps of which are only capable of being reduced ten times, and the bolt step only five times, the number of combinations will be *720* by *10* by *6* by *5* by *3 = 648,000*. On the other hand, in larger keys, the steps of which could be reduced thirty times, and the bolt-step twenty times, the total number of combinations will be *720* by *30* by *6* by *20* by *3 = 7,776,000*.

Our readers will most likely remark that this lock ought indeed to be secure, combining, as it does, improvements secured by no less than six patents, but most of the so-called improvements we consider the reverse, as we believe the *original* lock, with its simple detector and regulating-bolt, the most meritorious, as well as the most secure, of any of the subsequent inventions.

DYASS'S LOCK, invented about 1818.

Dyass was the inventor of the semi-circular bolt lock. The bolt of the lock was flush, and there were no limbs projecting from the link-plate. This contrivance made the lock very convenient to use. It was cheap, and had an excellent sale.

It is supposed the same inventor introduced the common *flush-bolt or dog-lock,* in which the bolt is moved by a limb called a "dog" working on the drill-pin.

SMITH'S LOCK, invented about 1818.

Smith is supposed to have been the inventor of the *flush-bolt* Bramah desk-lock. The bolt, which is of a semi-circular form, works out of the selvage, and is driven forward by a curiously-formed scroll or eccentric perforation in the bolt. He also very much improved the flush-handle.

WRIGHT's LOCK, invented about 1818.

The peculiarity in the construction of Wright's lock was that no key was required to open it. The drill-pin was riveted into a slide that formed a spring-catch. To open the lock, the drill-pin was pulled down with any convenient instrument to release the catch; but if a key were put on the drill-pin, the keyhole being made very close, it would not come down. In trunk, letter-bag, and similar locks, the thumb-nail was sufficient to pull down the moveable drill-pin which released the bolt.

STRUTT's LOCK, Patent dated October 18, 1819.

Although the construction of this lock rendered it tolerably secure at the period of its invention, and although it was not an expensive one to make, its adoption was never considerable, and at the present time it is scarcely used at all.

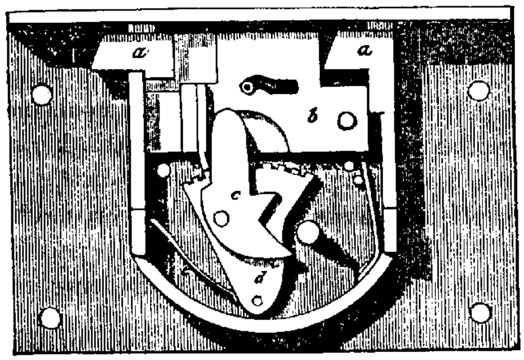

Figure 174. Strutt's Lock

A serious objection to its use is the circumstance of the key having a *reverse* action, *i. e.* after locking, the key is moved a short distance in the opposite, or unlocking direction, before withdrawing it from the keyhole.

Figure 174 represents a spring-box or desk-lock; *a a* are those parts of the bolt *b* which lock into the link-plate. *i* is the top lever which moves the bolt at the same time that the under-levers with the notches on their circumference are acted upon by the true key.

We cannot better explain its construction than in the words of the patentee himself. He states that "the advantages attempted to be obtained by the patentee of this (which was originally invented for private use) are: *perfect security, simplicity, strength, and durability, moderate price,* and a construction allowing the use of *one master key* to a very great number of locks.

"The security of the lock depends on combination carried to a very great extent, so far that any person acquainted with the principle would never think of attempting to *pick* a lock of this kind. In addition to this, deceiving notches on the edges of the plates or levers most effectively mislead the pick-lock, and make him think he is proceeding properly, when he is as far from doing

so as possible.”

“Much has been said about the facility of making false keys to any locks of moderate price. In this lock the key acts upon the plates near their center, and the notches (which allow the bolt to be shot when they coincide) are at the circumference; hence the slightest variation in the false keys from the true one causes these notches not to coincide, and until that is the case the locks cannot be opened."

It must also be remembered that the true key is made at random, and the notches in the plates made afterwards. Now the chances are almost innumerable against the steps on the web of the key being any regular curve, or the curve of one step being similar to the curve of another step. It is impossible, too, for any person to ascertain on what part of each step on the key each plate or lever rests; and the difficulty of taking any impression in wax, etc. sufficiently accurate to work from, will be very obvious to any person conversant with this subject.

“For the strength, simplicity, and durability of this lock, it will only be necessary to say that the parts are all large and strong, the friction very trifling, and the use of springs unnecessary in all larger sorts of locks, such as are used for doors, gates, etc. This in external or damp situations contributes materially to their durability.”

“It allows of a master key to suit of any number of locks, and even of a sub-master key, without increasing the works, or diminishing the simplicity in the least degree: for suppose any number of locks of the same size to be made, each having a different key, if another key having its steps made at random was introduced into each lock, and a set of nicks cut in the plates to allow the bolts to be shot, it would then be a master key capable of opening that set of locks.”

“Again, let another key be made at random, and introduced into any part of that set, say 10, 20, or 30, and nicks made in the plates to allow the bolts to shoot, that would then be a sub-master key, capable of opening that 10, 20, or 30 locks and no other. It must be observed that the space obtained on the circumference of the plates is so very large as to allow of several sets of nicks, and yet to leave an immense number of changes. Locks in suit may be made capable of millions of changes.”

"Another of advantage is, that if the master key to a large set of these locks is lost (a very serious thing in all other locks), the nicks in the plates brought into action by that key may, at a very trifling expense, be soldered or otherwise filled up, a new key and fresh nicks made, and the lost key thus rendered entirely useless."

In this lock, the stump is loose and is attached to the main-bolt, but does not move with it; but as the bolt moves there is a stump on the main-bolt which works through a curiously-formed slot in the loose tongue which carries the stump or blade. As soon as pressure is applied to the lever that works the main bolt (which may be termed an auxiliary, the key not touching the bolt), the stump on the loose tongue falls into the false notches in the levers. This is consequently the first *moveable stump* lock on record, as well as the first with *false notches.*

SPICER'S LOCK, invented about 1819.

This lock is constructed with *double fly-talons* or *detents,* which are applicable also to spring-bolts or latches, and which by this improvement are made self-acting or locking. A small stud projects out of the selvage or fore-end of the lock, which by coming in contact with the staple or striking-plate releases the main-bolt, which then shoots and fastens into the staple.

This inventor is supposed to have been the first who introduced the imitation or "sham" Bramah lock; also the first who shut up the keyhole of locks by the limb termed "bang-up," which consists of either a thin steel spring working over the drill-pin, or a scroll spring driving up a thin disc of metal.

He also introduced the common book-lock, so very extensively used at the present time. He was considered in his day one of the most ingenious workmen in the trade, and when he declined the business he *sold* his principal workman for 42 Pounds to a manufacturer in Birmingham. This custom of buying and selling workmen still prevails in the trade. We shall make some observations on this practice in a future chapter.

We may observe in connection with Spicer's book lock that about the year 1825, the late Mr. Mordan introduced a Bramah book or ledger-lock, which was cast solid in the same manner as the solid locks of Milner, recently patented.

MALLET'S LOCK, Patent dated December 14, 1820.

This lock is of a complicated character, and is constructed with sliding guards in the place of tumblers or levers. These sliding guards, with a "**barricaded-guider(494)**" and a *barrel and curtain,* form the peculiar limbs of this lock, and it is quite evident that the "barricaded-guider" was intended as an improvement upon **Bird's** lock, invented in 1790, and described earlier. Figure 175 is a perspective representation of the lock with the key in it, and the bolt *b b* half way in the passages or gatings of the sliding guards. *a a* is the lock-plate.

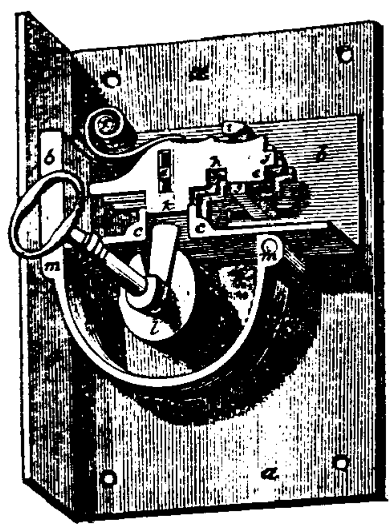

Figure 175. Mallets Lock

On the bolt is fastened the barricaded-guider *c c; d* is a guide-stud which keeps the sliding-guards *e e e,* when moving in a parallel line, from much friction; *f* is the center-pin on which the end of the split-spring is fastened, and round which it plays.

The barricaded-guider *c*, the guide-stud *d*, and center fixed pin *f*, are all attached to the bolt *b*, and move in the lock-plate, *a a*, forward and backward in locking and unlocking is a stud riveted to the lock-plate *a*, which keeps the bolt locked or unlocked by standing beyond the sliding guards when the bolt is shut out or locked; and the notch *h*, when the bolt is withdrawn or unlocked.

i is a guard-stud, also riveted to the lock-plate, between which

and *g* the sliding-guards must pass with great nicety in locking and unlocking. There is a small projection *i* on the back of the sliding-guards, which, when they are all raised to the height wished by the manufacturer, keeps the lines or surfaces of them which are exposed to the action of the key, or any other instrument, by which the lock might be attempted to be picked, in the same plane with each other, higher, but parallel with the surface of the barricaded-guider, or in a variety of places different from the steps of the keybit as required.

The use of this arrangement is to prevent any indication of the corresponding steps of the key-bit, which, if they were not thus stopped, could be ascertained by raising them. *L* is a moveable collar, playing in circular holes, into which it is fixed in the cap and plate of the lock; the part of the collar at the letter of reference (1) is the entire breadth or depth, and it prevents, therefore, the plates being crushed together, while its outer diameter is so large that its periphery comes nearly in contact with the bolt, barricaded-guider, and sliding-guards in their passage, occupying the space of the ward with more effect and at less expense, and therefore rendering it difficult, if not impossible, to introduce the pick-locks in general use to operate on the sliding-guards to open the lock.

m m is the outer rim of the lock, which meets the bolt and the barricaded-guider at each extremity, and when the cap is on, prevents damp and dust from rusting or impeding the action of the spring or the works.

There is a notch in the top of the front of the collar, into which falls a lever-bolt, for the purpose of preventing the collar from being turned round. When the key is introduced and passed through the collar, it presses the reverse end of the lever, and brings the lever-bolt out of the notch, by which the collar is enabled to turn round. This, the patentee states, "is an additional security to the lock, as it is obvious that without lifting the lever, the collar could not be passed round so as to get at the sliding-guards."

A plainer description of the modern “barrel and curtain," patented by Mr. De la Fons in 1846, and claimed by him as his own original invention, could not be written.

AINGER’S LOCK, invented about 1820.

In the construction of this lock, the two following objects were

proposed: In the first place, to render it more difficult of violation by a pick than those in general use; and in the second, to apply a key to it, of which no ordinary person could take an impress, and which, even in a workman's hands, would be very difficult of imitation.

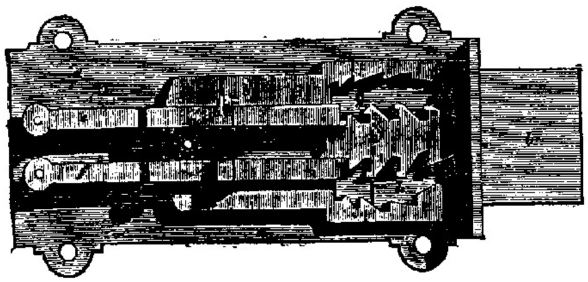

Figure 176.

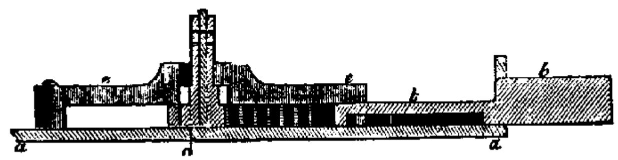

Figure 177.

Figures 176 and 177 represent a plan and section of the lock divested of the key, and of the springs which press the tumblers towards each other: *a a* is the plate or case of the lock; *b b* the bolt which is moved by a pinion *c*, acting in a rack *d; e f* are the tumblers of which four or more might be used, though two are sufficient to exhibit what are deemed the improvements.

These tumblers have projections at their ends, which clip into the grooves *g h* cut in the bolt. The projection of *e* (see figure 177) is equal to twice the thickness of that part of the bolt in which the grooves are formed, but the projection from *f* is only half that quantity, in order to avoid in its passage the spring *i*, which is seen across the groove *h*, and whose situation under the bolt is described by a dotted line.

Figure 178.

The shape of the projection is shown at *k,* figure 178: they are guided by the key through the grooves, as will be described. It is first, however requisite to explain the nature and effect of the spring *i*.

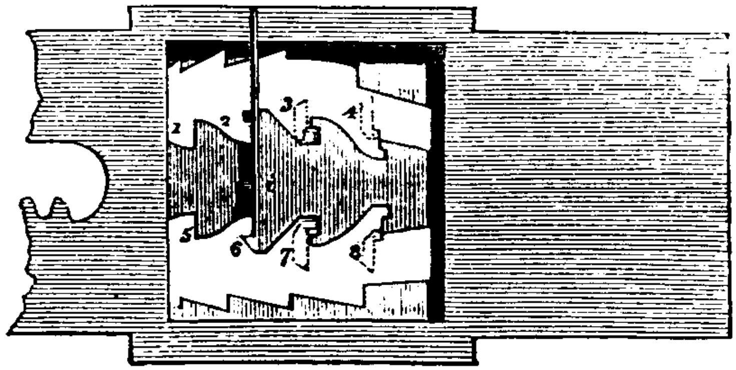

Figure 179.

Figure 179 shows the underside of the bolt, with the grooves and the notches on a larger scale; it also exhibits the partial reduction of half its thickness, in order to contain the spring. The notches *1, 2, 3, 4, 5, 7,* and *8* are similar in their nature and mode of action to the securities already applied to locks of various descriptions: it, will be seen that the notches *2, 3, 4, 7,* and *8* have a hook or beak not attached to Nos. *1* and *5*.

In the notch *8* this hook or beak is formed by a catch at the end of the spring *i*, so that it will recede towards *7* by a slight pressure on its beveled edge; its capability of doing this totally prevents the possibility of disengaging one tumbler from the notches at a time, which is the practice pursued in attempting to pick locks, and by which means the tumblers are removed from the situations in which the pressure of the springs places them, as is shown by the dotted lines in *3* and *7*, and they are placed one after the other, as described in *4* and *8*, in which position they offer no impediment to the motion of the bolt.

This effect cannot be accomplished in the notches *2* and *6*, care being taken that the projection made by the spring be somewhat greater than that in the opposite notch. When this is the case, if, for instance, it was attempted to relieve the tumbler out of No. *2* first, it is evident it would fall in again before No. *6* could be disengaged, and the contrary mode is impossible, because, as soon as the pick ceases to act on the tumbler, its pressure would repel the spring, and it would again take its old situation.

"The form of the key is described in figures 180 and 181; the lower part of figure 181, is supposed to be a section showing the internal chamber, or pipe, in three divisions, the upper and lower being circular, and the middle one triangular."

Figure 180.

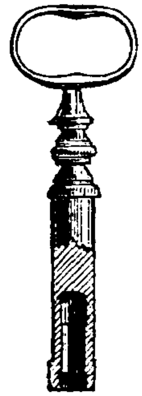

Figure 180.

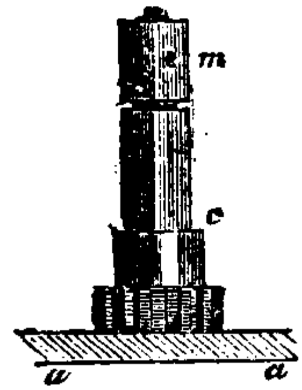

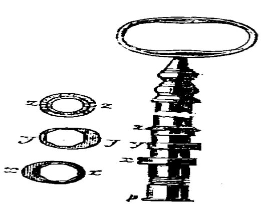

Figure 182.

The use of these three parts may be better understood by referring to figure 182, which is the pinion *c*, drawn on a larger scale; *a a* is part of the lock-plate in which an iron pin is fixed; round this pin the cannon-pinion *c* turns, having the lower part of its barrel circular, and the upper part formed of as large a triangle as can be inscribed in the circle, and having one side circular, as seen in figure 176.

Immediately above, on the extremity of the iron pin, is fixed a similarly shaped piece of metal *m*, secured from revolving by a pin passing through it. When, therefore, the key is introduced, this part not turning, with the rest, it requires that a second portion of the chamber should be cylindrical, to permit its remaining stationary during the motion of the key.

To the lower extremity of the key are attached two irregularly curved collars, *n* and *o*, figure 180, each of which acts on one tumbler, and causes them, during the motion of the bolt, to describe curves similar to the grooves *g* and *h*. To prevent either collar from touching the tumbler for which it is not intended, a portion of each of the latter (being the upper part of one and the lower part of the other) is removed. (See figures 177 and 178.)

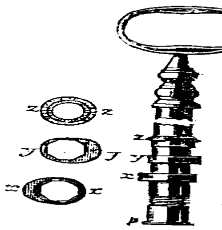

Figure 183.

Figure 184.

Figure 183 describes the means of making a secret or master key on this principle: the lower part of the pipe (which is supposed to be manufactured in two lengths, and afterwards brazed together), is formed into an octagon and surmounted by a screw; the pieces *x* and *y*, similar in their nature to the collars before described, and having octagonal perforations, are to be slipped on to the pipe of the key, and followed by the screw-nut z. The two lengths of the key, being then soldered or brazed together, the three pieces x y and z can never be lost, being secured from coming off by a small fillet p, which buries itself in a recess formed in the piece x for that purpose.

The appearance of the key, when the collars are on the octagon and the nut screwed down, is described in figure 184. Though the collars cannot be wholly removed, it is evident that by withdrawing them from the octangular to the cylindrical portion of the key, they may be turned round, and made to take any required position on the octagon; and if letters or figures were engraved on each of its sides, the collars might be withdrawn and returned to their places by the person acquainted with the secret, while to others there would be 512 chances to one against their being able to make use of it.

"Figures 185 and 186 exhibit the means of rendering a drawback lock as difficult to pick when on the first shoot as when doubled locked: q q is the bolt acted on by the spring t, and having the piece s attached to it; r is an inner or secondary bolt, to which may be applied any species of security now in use for locks. It requires only to be made long enough to receive the apparatus for giving it such security, and therefore its length is not defined. It is connected with the bolt q by a stud holding in the piece s, thus permitting the latter to recede by striking against the staple, while the keyhole having communication only with the inner or secured bolt r, there will be as much difficulty in picking it while on the latch or first shoot as in other cases when double locked."

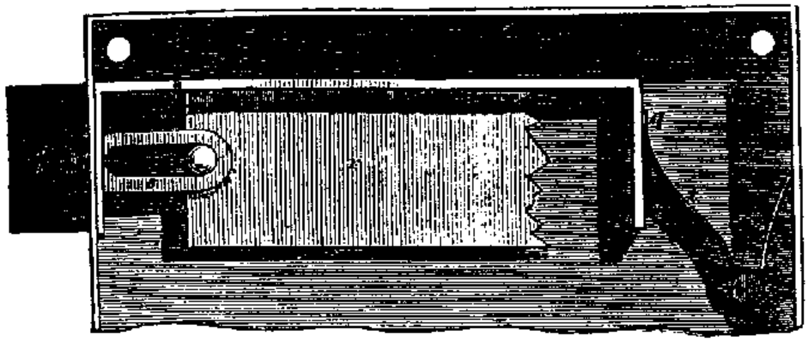

Figure 185. Drawback locking mechanism

Figure 186. Drawback locking mechanism

COPE's LOCK, Invested About 1821.

Cope was the inventor of the rivet lock, and also the lock in the form of a pocket telescope, as well as the doubled-bolted escutcheon lock, the mortise padlock, the fancy or ornamental portfolio lock, the secret link lock, and the jointed link lock, i.e., making the links to lie flush with the link-plate.

FAIRBANK's LOCK, Patent Dated July 10, 1823.

This lock is the invention of a foreigner, who communicated the construction to Mr. Fairbanks, an American gentleman, who at the time resided in London. "The improvement consists simply in the employment of a spiral or worm spring, instead of the Scotch spring." In other respects it is simply a common tumbler lock. The advantages claimed for this lock are that the bolts or latches are moved with greater ease than by any other sort of spring; and also that the spiral springs, whether constructed to exert their force by expansion or contraction, are more durable, and less likely to get out of order than any other description of springs hitherto applied to locks and latches.

WARD's LOCK, Patent Dated November 13, 1823.

This lock was constructed with five levers; two lifted up and two were drawn down, and the top lever worked across the others, and kept them form moving either up or down. The key was made with a

jointed bit, and so constructed that when it was inserted in the lock and turned round the bit elongated, and thus carried the bolt or levers, whichever was desired.

DUCE's QUADRUPLE LOCK, Invented About 1823.

This lock was especially invented for the purpose of securing iron safes and chests. With a single turn of the key it throws out four bolts, one at right angles to each side of the lock; and would, therefore, prevent any door to which it is applied from being opened, even if the hinges were cut away. "It is a combination for four distinct single-bolt locks, fixed in the same frame and opened by the same key; the bolts, therefore, are shot or withdrawn in succession, and present the two following advantages: whatever time and trouble may be required for picking one of the locks must be quadrupled before the whole can be opened; and as the key opens the four locks in succession, the strain on the wards will be much less than in those cases where two or more bolts are moved simultaneously.

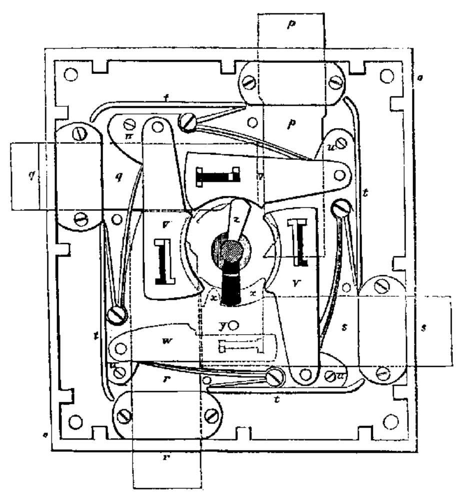

Figure 187. Duce's Quadruple Lock

Figure 187 represents a front view of the lock with the bolts shot out. *o o* the case, *p p* the first bolt, *q q* the second, *r r* the third, and *s s* the fourth bolt; the upper plate is removed, and the lock rests on the inner casing *t t t t*; *u u u u* an inner plate, *v v v* three levers lying on it for the three first bolts.

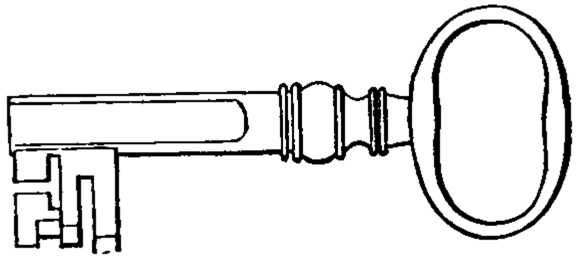

Figure 188. The Key

Beneath each of these levers, and under the plate *u u*, are two more levers, making three for each of these bolts; the last bolt *s s* has but one lever *w*, placed under the plate *u u*, which is moved by the corners of an intermediate piece *x x*, which turns on the pin *y*, as is shown by dotted lines: the key *z* is represented as having thrown out the first bolt *p*, and beginning to protrude the second *q* ; it then acts on the bolt *r*, and lastly on the bolt *s*, moving them to places shown by dotted lines. It withdraws the three first bolts in a reverse order, but finishes with the last *s s*, in either case. The levers are of the ordinary kind.

YOUNG'S LOCK, Patent dated May 14th, 1825.

The construction of this lock was intended as an improvement on Barron's, and was particularly adapted to *stock* locks. The tumblers have two stumps each, one behind, and the other before the bolt, which is racked both on the top and bottom edges.

Over-lifting would in place of lifting a single stump (as in Barron's, out of one notch into another in the bolt) lift the bottom stump in the tumbler into the rack in the bolt. If under-lifted, the top stump would not leave the top rack. In addition to that, there is a revolving-plate working round the drill-pin at the bottom of the lock, which revolving-plate or "swivel," as the patentee calls it, is acted on by a forked spring having a tendency to drive it towards the front of the lock.

This plate has a notch in it, and there is a projection or hook fixed to the back-plate, corresponding in position with the notch in the plate. When the key is pushed in, it depresses the plate, and allows it by means of the notch in it to descend below the hook and pass under it. The swivel also has a pin in it, which locks into a hole in the bolt until it is depressed by the key. As any instrument pressed into the lock would depress the plate and free both it and the bolt, it is manifest that this "swivel"

is of no benefit whatever, while the reversal of the Barron's tumbler affords no improvement in security, and we should think was not quicker made. The improvements were applicable to all kinds of locks.

Another improvement consists in a peculiar mode of cutting out the wood in stock locks. Previous to this period, the oblong-shaped cavity in the stock for the works of the lock to occupy was sawn out; but by this improvement the chamber is formed of a circular shape, which is cut out by a tool in a lathe; and this gives the lock a much neater appearance.

FRIEND'S SECRET LOCK, invented about 1825.

This is a dial lock, which requires the aid of a key to lock and unlock. The inventor states that "Keys or pick-locks are of no use in opening it. The key that belongs to it is of no use to any person without the guide, which is so portable as to be put into a pocketbook, and can be varied in such a manner in a few seconds, by such an indefinite number of movements, as to put it out of the power of any person to open it, even if he is in possession of *the guide,* unless he is acquainted with the numbers to which it is set.

This renders it safe, strong, compact, and secure. To open the lock, you will observe on the guide two circles, with the numbers 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, on each, and the stops are now set at 2, 6. Put on the guide to the front of the lock, with the number 1 upward toward the bolt, so that the stops go into the grooves in the plugs. Introduce the key and turn it round, until you can take it out again. You will find the lock open.

Now if you take off the guide, it cannot be shut or locked so as to take out the key; because every time the key comes to be taken out it is open. To shut the lock, put on the guide, and turn the key any part of the way round; then take off the guide. You will find it shut and secure. You may turn the key as often as you please without any effect.

The advantages which the inventor conceives the lock to possess are: (1) That it cannot be picked, (2) That a *facsimile* key cannot unlock it, (3) That the true key cannot unlock it without the guide, (4) That even with the true key and the guide in the hands of strangers, the lock is secure, unless the secret of the numbers set to the lock be known.

Figures 189 and 190 are back-views of the lock, the plate being removed; *A* the bolt; it has two arms with studs *b b,* projecting forwards, and a point *c*, which form three bearings or supports, all or either of which are sufficient to keep the bolt out; *d d,* a spring, the action of which is to withdraw the bolt; *e e,* two similar plates, with notches to receive the studs *b b; f*, a third plate, with a notch to receive the point *c*.

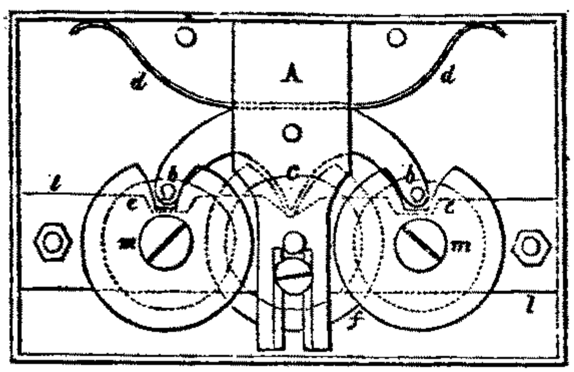

Figure 189.

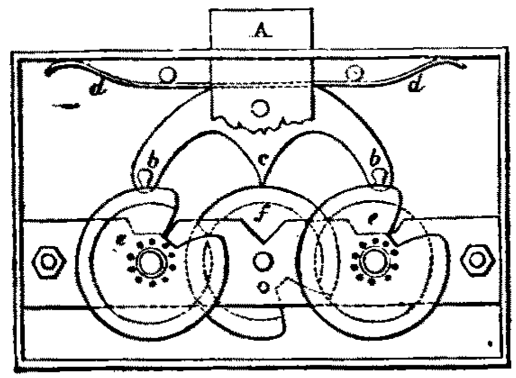

Figure 190.

In figure 189 the notches of all the three plates coincide with the studs, the obstacles to the action of the spring *d,* therefore, are withdrawn, and the bolt retracts. Figure 191 shows the front of the lock. When the key is introduced and turned, it moves the plate f, figure 189, and thus, by raising the point *c* out of the notch, it protrudes the bolt, and as the three plates are connected together by three toothed wheels, shown in figure 192, they all move and keep the bolt protruded, but when the key is turned quite round to withdraw it, the plates again agree with the studs, and the bolt is withdrawn or unlocked; the notch in the middle plate *f* always agrees with the point *c* when the key is withdrawn. Therefore, to leave it unlocked it is requisite to derange the three plates, as shown in figure 190.

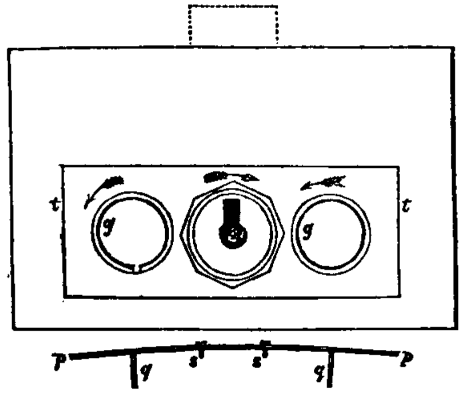

Figure 191.

This is effected by the peculiar construction of the axis *s*, which carries the plates *e e,* one of them is shown, with all the parts separated in figure 198*; g* the axis (the bottom face of which is seen in *g,* figure 191, showing a groove nearly all round it, in which is fixed an upright pin *h.*

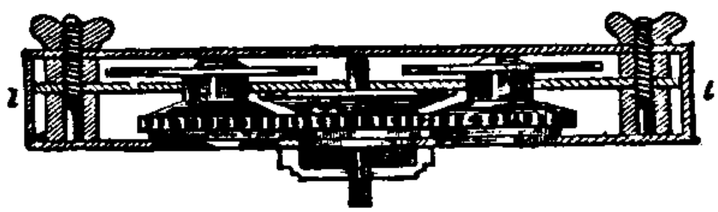

Figure 192.

i is the toothed wheel which first goes on the axis *g; j* a strong spring nut which follows it, and is pinned on so as to hold the wheel very tight, and yet allow it to move alone by applying additional force. Over this goes the bar *l l,* figures 189, 190, and 192, the holes of which are large enough for the nuts *j* to project through.

Over this is lastly put on the notched plate *e*, which fits on the axis *g*, and is screwed tight against the nut *j* by the screw *m*, which enters the end of the axis *g*. In figure 190 the screws are removed to show the plates *e e* and the end of axis *g*. Now in order to prevent each of these plates from turning without its axis *s*, there are ten holes round the center hole, shown in figure 196, and a pin *k,* figure 193, is fixed on one side of the top of the nut *j*, which enters one of these holes and secures it.

Figure 193.

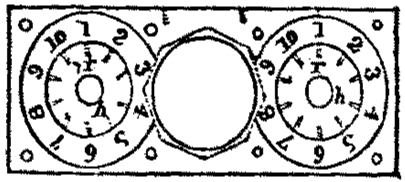

Figure 194.

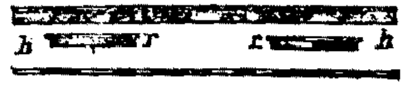

Figure 195.

Figure 197 shows the middle toothed wheel and notched plate *f*, with the axis *o* separate; they are all screwed together by the side screw. Figure 198 shows the front of the axis, with the notch to receive the projection *n* of the key, figure *199.*

o, figure 197 is the end which enters the key. Having described the wheels and their axis, it remains to describe the governor or secret guide plate, which, with the key, either arranges or disarranges the plates. Figure 194 shows the guide plate.

Figure 195 is a section with the parts separated; it has an octagonal hole, which fits on the octagonal projection round the keyhole in figure 191, on each side, and within the circles of numbers are moveable circular-plates r r, having ten holes round their circumference corresponding to the ten numbers.

p p is a spring which screws against the edge of the plate by the screws s s, but is separated here to show the pins q q, each of which, passing through the edge, enters one of the ten holes in the moveable plates r r, and secures them from turning round, by which means the steps or guide-pins h h are fixed at any chosen number.

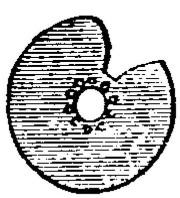

Figure 196.

Figure 197.

Here they are at 6 and 3. Now when this guide plate is put on the face of the lock, as shown by the dotted lines *t t*, figure 191, the pins h h enter the grooves round the face of the axis *g*, and it will be seen that the stops or ends of the grooves correspond with the stopping pins *h*; then, on turning the key any portion round, the middle plate *f* turns and protrudes the bolt, while the two side-plates *e e* are prevented from turning by the pins *h h* in

the grooves *g g*, their respective toothed wheels only turning.

Then, on removing the plate and continuing to turn the key, they will all three move and appear as in figure 190, all supporting the bolt as they disagree.

By continuing to turn the key, the bolt can never be withdrawn, though when the key is taken out, the side-plates only support the bolt. Then to unlock it, put the guide-plate on again and turn the key; all the three notched plates will now move until the end of the grooves *g g,* figure 191, come in contact with the stopping-pins *h h,* which detain the side-plates *e e* in their right places, as figure 189, and continuing to turn the key until it will come out, the middle-plate also agrees, and the bolt is thrown down by the spring *d*.

If it be required to alter the secret, raise up the spring *f*, figure 194, withdraw the pins *q q,* then turn the plates *r r* until the pins *h h* coincide with the intended numbers, and the pins *q q* will fix them.

Figure 198.

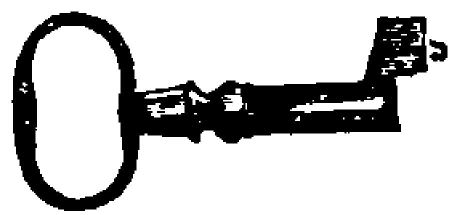

Figure 199.

Then put it on the face of the lock, introduce the key, and turn it quite round, and take it out again; the stops will then have detained the axis *g g* at the right places.

Then open the back of the lock, withdraw the screws *m m lift* up the notch-plates *e e,* which will be found in some such position as in figure 190 (but the middle-plate, when the key is out, is always found as in figure 189), and place them on again as figure 189.

The ten holes round their centers allow ten changes of position in each, screw them fast, and finally shut up the lock. If either one or both the moveable guide-plates *r r* be altered, the lock cannot then be opened; they must be returned to the right numbers which you keep secret before it can be opened.

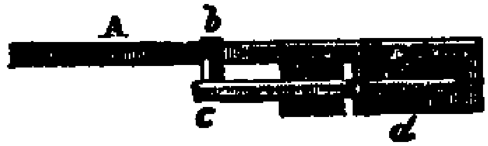

Figure 200.

In figure 190, the tail of the bolt is broken away to show the under parts. Figure 200 a side view of the bolt.

RUBERRY'S BAG-IRON LOCK, invented about 1826.

Ruberry was the inventor of the "bag-iron," and the bag-iron lock so extensively used for carpet and leather bags. He entered a caveat to secure the invention, but would not complete the patent, as he thought it was too simple, and was afraid the locks would not sell. His timidity lost him a large fortune, as the sale of them was from the first very considerable.

RICHARDS' LOCK, invented about 1827.

The inventor called his device a *fixed* lever lock. The peculiarity of the construction consists in the shape of that part of the levers that come in contact with the v-end of the detector. When one or more of the levers are over-lifted in any surreptitious attempt to open the lock, the projecting arms of the levers are forced beyond the v-end of the detector, which keeps them in a fixed position. The detector is released in the usual way, by turning the key in the direction of locking out the bolt.

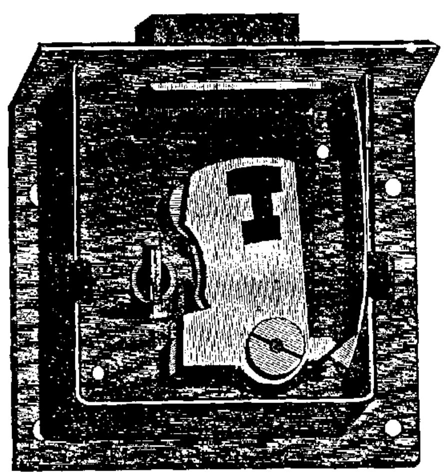

Figure 201.-Richards' Fixed Lever Lock

MACHIN'S LOCK, invented about 1827.

The peculiarity in the construction of Machin's lock consisted in having eccentric wards, which required a key with an expanding bit. “In this key the bolt or lever which raises the tumblers and shoots the bolt is moveable on a countersunk pin, so that it may slide thereon, and thus be drawn one-eighth of an inch from the barrel.”

“The hole in the escutcheon-plate is of such a length as to admit the key only when the bit is pressed close up to the barrel. When the key in this state is introduced, and is begun to be turned round, one of the notches in the bit takes into a raised circular edge of steel, placed eccentric with regard to the lock-pin; so that as the key is turned the bit is drawn out, and is at its greatest elongation when it arrives at the tumblers and other moveable parts of the lock. Hence it is obvious that no common or skeleton key that could pass the escutcheon-plate would have a bit long enough to reach the tumblers and shoot the bolt."

In figure 202 *a a* and *b b* (figure 203) are the wards which are made eccentric, the shortest distance being under the keyhole, and the longest towards the bolt. The shortened key is provided with a sliding bit *c* (figures 205, 206, and 207), which is gradually brought out by the eccentric wards until it becomes long enough both to arrange the tumblers and move the bolt, and continuing to turn the key round, the sliding bit *c*, is returned or slid back until it is short enough to come out of the hole.

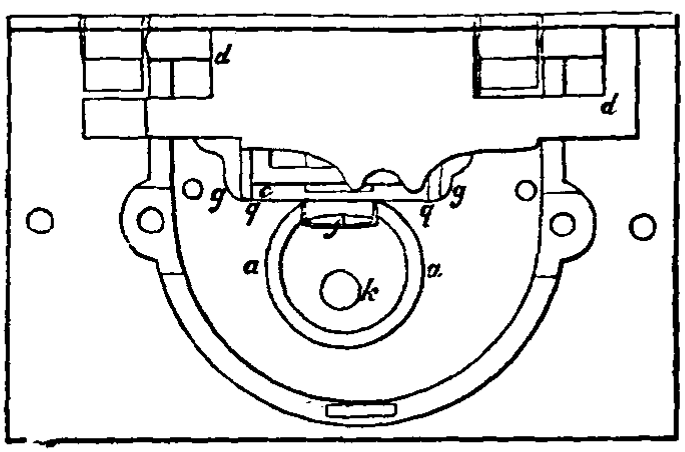

Figure 202.

d d (figure 202) is the bolt, and *e* and *f* parts of the tumblers

under it.

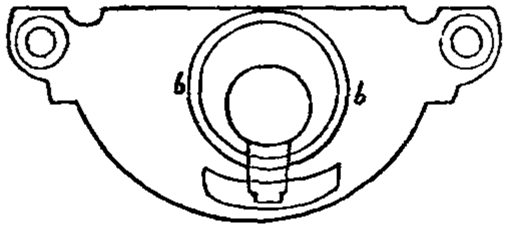

Figure 203.

Figure 203 represents the inside of the cap, which contains the upper ward *b b.*

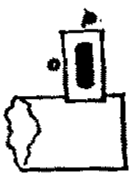

Figure 204.

Figure 205.

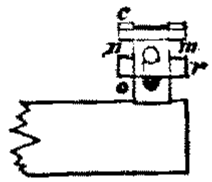

Figure 206.

Figure 207.

The key (figure 205), is partly sectioned, and at different places, purposely to show the thin tube within the pipe which retains the spring and the loose metal plate *s* in their places; the sliding bit *c* is here close, ready to enter the lock; in figures 206 and 207 the bit *c* is shown extended long enough to move the bolt.

CHUBB'S COMBINATION LATCH, Patent dated May 7, 1828.

The object of the improvements introduced by, Mr. Chubb was to render latches of the ordinary description more secure from being lifted or unfastened from the outside of the door or gate by means of pick-locks or false keys. In his specification he states,

"The essential principle of my improvements in the construction of latches, which may be used for fastening doors or gates, consists in combining, two, three, four, or more distinct moveable latches to act in concert for one fastening. They are applied side by side in parallel planes, or one behind the other, all being mounted on one center-pin, and being moveable about the same, but so as that each latch may be capable of such movement by itself, quite independently of the movements of all the other latches, and the outer or moveable ends of all the said combined latches are adapted to engage or catch which or behind the hooked

part of one fixed hasp, and thereby to secure the door or gate from being opened in the same manner as the single latch commonly used."

In addition to the said fixed hasp, so adapted to receive the ends of my combined latches, it is formed with two hooked or catching parts, one disposed opposite to the other, in such manner that the combined latches cannot be unfastened, unless the outer end of every one of the separate latches is previously raised, moved, or lifted (either by the key or by the pick-locks, or by the handle) in such manner as will place all those ends in one precise position.

They must all resume that position at the same time, for in that position alone can the outer ends of the combined latches be disengaged or unfastened, so as to withdraw them from between the opposite points of the double-hooked catches or catching parts of the fixed hasp, because by my arrangement of such combined latches and double catches to the hasp, if the outer end of any one of the latches is moved too far or beyond that precise position, or if any one is not moved far enough, that one latch which so fails of being precisely placed will catch behind one or other of the hooked parts of the hasp in a sufficient manner to secure the door, even though all the other latches may be properly placed, so as to offer no impediment to unfastening.

WALTON'S IMPROVEMENTS IN LOCKS, invented at various periods from 1828 to 1846.

The inventive genius of this family of Wolverhampton locksmiths has perhaps never been equaled by any other members of the trade. They have for many years manifested a happy turn in introducing such improvements into the construction of locks as made them very showy and tolerably secure. They appeared to be always ready with some fresh notion, or with an old one improved. We shall here enumerate such improvements as are known to have emanated from them.

They invented:

The double-handed lock and latch, so constructed as to suit either the right or left hand side of a door;
The double keyholes to locks and latches;
Bolts to double-handed cupboard locks;
The stock lock called “Steele's patent," which is a double-handed stock lock, the lock being inserted in the cavity cut out of the

stock, or mortised therein;
The Gothic-formed cupboard and other locks;
The solid-bolt stock lock;
The boxed-up stock lock;
The back-racked stock lock;
The moveable nose-ward lock;
The H-formed slide lever lock. The levers in this lock are forced down by a spring and follow motion, one to each lever;
The crank-shackled padlock; the round padlock; the solid padlock; and the revolving-wheel padlock;
A beautiful wheel motion to locks. The levers are made of a peculiar form, and worked in racks cut out of the back part of them. A blue-steel ward is fixed upon the levers, so that the key takes both wards and levers, which, by moving together, shoot the main-bolt. This lock had an excellent run;
A very peculiar latch-bolt, which worked from a small pin motion, the key working through a niche into the bolt to draw it back;
Detecting levers, which detect by an under-lift as well as an over-lift. This is effected by a v-formed nose-spring catching in notches on the face of the levers.

They also improved the narrow mortise lock, by cutting out a channel in the main-bolt and working the latch therein, or *vice versa.* This is a neat and useful contrivance, as when the main-bolt is locked out, it also fastens the latch, making together a very strong bolt.

We are sorry to record that for want of a cheap mode of securing inventions to the inventors, the benefits which ought to have accrued to the Messrs. Walton have been entirely lost, for no sooner had they brought out a new lock, or introduced an improvement into others, than the same articles were made by **other makers(495)**, of lighter materials and in a much inferior manner, and being offered to the factors at lower prices, were invariably purchased, and thus completely shutting the inventors out of the market. They have used their talents for upwards of a quarter of a century in inventing and improving locks, without receiving that remuneration which such ingenuity and unwearied exertions justly merit.

There is a custom that prevails almost universally, not only in this but almost in every other trade, which deserves to be censured, and which in the absence of any law to the contrary, can only be amended by a strict regard to a sense of honor and integrity. We mean the practice of procuring all invention or a

design from a person, giving him a small order for the particular article, and then giving the pattern to another maker to be made at a lower price.

Another feature of this same principle is one manufacturer copying the designs of another, and also the size, and shape, and character of his name-plate or trade-mark, and in some cases, the name of the manufacturer also, in order to give the imitation the exact appearance of the original and genuine article.

GOTTLIEB'S LOCK, Patent dated June 21, 1829.

The improvement for which Mr. Gottlieb took out his patent "consisted in the application of a piece of paper over the keyhole, so secured as to prevent its being removed without the introduction of a key passing through it; and hence any attempt to break open the lock would be indicated by the fracture of the paper."

"The paper is introduced and secured by means of a folding-shield with a hole in it, similar to the keyhole in a lock-plate; this shield is kept down by a spring-catch, which cannot be disengaged for the introduction of a fresh piece of paper except by the proper key, which is furnished with a projecting stud on the side of the key-stem, for the purpose of disengaging the shield-catch when turned."

"As a source of further security, the patentee proposes to employ cheque-paper, with some design engraved upon it; and by having this paper bound in a cheque-book, and a leaf torn off when required, so that the paper found in the keyhole at any time being compared with the edge of the leaf in the book, the substitution of another paper would be discovered. There are few cases in which this plan can be advantageously employed."

STANLEY's LOCK, invented about 1829.

Stanley's lock was constructed with a double set of levers, and with a double-bitted key, or rather it was two locks in one; a lock on each side of the keyhole.

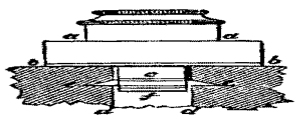
CARPENTER & YOUNG'S LOCK, Patent dated January 18, 1830.

The object of the inventors appears from the specification to be the production of locks of greater security and stability than the common locks, without augmenting the cost; and also to

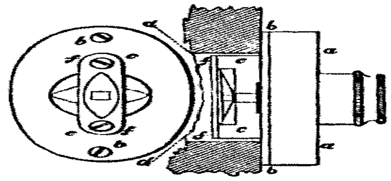
construct a latch-lock somewhat more convenient in use.

The greater degree of security is obtained by having a double set of tumblers, one set attached to and moveable with the bolt, and the other attached to the plate of the lock in the usual way. Projections from the stationary tumblers fit into slits in the moveable ones, when they are simultaneously elevated to a given position; and, in addition to this, there are notches cut in the upper and lower sides of the moveable tumblers, to fit fixed pins projecting from the plate, just above the notches on the upper side, and just below those of the under side when the door is locked, so that the bolt cannot be withdrawn except by a key, which raises each tumbler to an elevation coinciding precisely with the cuts in the original key, and upon this depends the security.

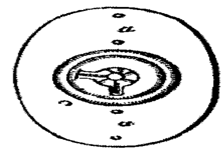
Instead of the usual latch or spring bolt to room-door locks, the patentees cause this part to drop into a notch in the striking-plate after it has been elevated by passing over an inclined plane upon it. In connection with this latch is a tumbler, by which it is elevated through the instrumentality of a key, by a handle on one side of the door and a key on the other, or by the key, without using the handle. These contrivances have manifest advantages, and are easily executed by any locksmith.



MORDAN'S LOCK PROTECTOR, invented about 1830.



Traveler's' chambers at inns are sometimes robbed because the locks on the doors are generally very insecure, and all on the same construction, so that a key which will open one lock will open them all. In order to prevent this, Mr. Mordan has invented a very portable escutcheon, by means of which a traveler may secure the door of his room from being opened during his absence, unless actual violence be used.



This escutcheon, or protector, has a short pipe, which, after the door has been locked, is thrust into the keyhole, and is furnished with a small lock, on the principle of Bramah's, or any other equally good, so contrived that, on turning its key, two lancet-shaped pieces fly out laterally and bury themselves in the wood; thus preventing the removal of the protector unless its own key is applied.

Figure 211 is the top or front of the lock; figure 210 a side view; figure 209 a back view; and figure 208 an end view.

view; figure 209 a back view; and figure 208 an end view.

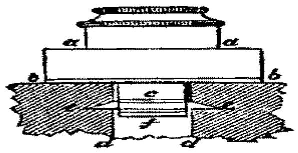


Figure 208.

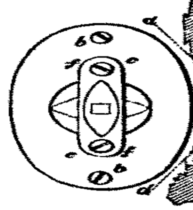

Figure 209.

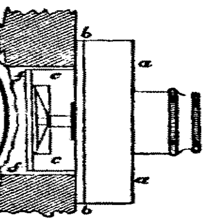

Figure 210.

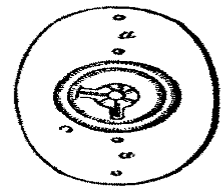

Figure 211.

a a the cap or case; *b b* the back-plate, from which rises a projection or pipe *c c,* formed to enter a keyhole with but little shake. Figure 210 shows it merely introduced, but not secured in the keyhole *d d,* which is in section. Figure 208 shows it secured.

This invention is a modification of the Bramah lock as applied by Mr. Russell to liquor cocks. "Within the case *a a* and its cylindrical prominence is a barrel or cylinder containing seven sliders; it ends in a strong central pin, which passes through the projection *c* into a recess, where it is squared to receive on it the steel-piece *e e,* (figure 208), which is pointed at each end like a strong, short penknife with a thick back. The cutting edges are, of course, on opposite sides, so as to follow.

Over this, and but just touching it, is screwed the steel-plate to guard its cutting edges when out of use, and keep it from coming off. When this is put into a keyhole, as figure 210, and pressed close, its key is introduced with the nib in the lower opening of figure 208, and turned until it comes out of the side opening.

It will then have turned the double cutter *e e* from its longitudinal position under the plate *f* to a cross one, both of which are shown by dotted lines in figure 209, and it will be secured to the lock by the two blades having cut their way into the wooden sides of the keyhole, as shown in figure 208, and cannot be pulled out until its own key has returned the cutters *e e* into their sheath *c c.*"

WALTERS' LOCK, invented about 1830.

The peculiarity of this lock consisted in the employment of levers above and below the chambers, which construction added considerably to the security as well as to the secrecy of the lock.

AUBIN'S LOCK, invented 1830.

The peculiarity of the construction of this lock consisted in working one tumbler under the bolt, and three or more levers on the top of the bolt; the whole working in combination with each other, together with a barrel and curtain.

About the same period, Mr. Aubin constructed another lock for room doors, to prevent seeing through the keyhole. This was accomplished by placing the keyhole on the one side of the lock, in a position at right angles to the one on the other side.

When the pin-end of the key was forced into the lock, it moved a slide from before the circular part of the keyhole, which thus allowed the pin to enter. Some of these locks were constructed the same as a one-sided lock, thereby giving the same amount of combination. Such locks of course had two keys, one for each side of the door; the bit on the one key was simply reversed on the shank of the other; that is, the terminal step in the one bit was at the bottom, while in the other it was at the top, and so with the other steps.

Mr. Aubin also constructed these locks with the pin-end of the key loose, so that it would move round independently of the key-bit, similar to a universal joint. This plan effectively prevents burglars' nippers having any effect upon the key-bit when the key is left in the lock.

Another contrivance by this inventor for securing the door of a room from the outside independently of the key, consists in what he calls “a protector," which is placed inside the keyhole, and secured by a padlock outside. To persons who engage rooms at hotels, and desire to be certain that no one can open the door, although he might have a duplicate key, this is undoubtedly a valuable contrivance.

He also invented an expanding wedge to place from the inside of the room under the bottom of the door, which was so constructed that by pushing the door from the outside only made the door the tighter.

Subsequently, Mr. Rudhall improved this wedge, by inserting between the bottom part and the top part a detonating ball, which the instant the door is forced from the outside, explodes with the report of a pistol-shot.

These simple contrivances are very useful and effective where the lock on one's chamber-door is a bad one, or where there is none at all.

RUTHERFORD's LOCK, Patent dated April 14, 1831.

The application of an inviolable lock to boxes sent by mails or other conveyances containing money or other valuable property, that can be opened only at stated **times(496)**, is, of course, an object of desirable attainment in a commercial country like this. For effecting this object, this patent was taken out in 1831 by William Rutherford, jr., of Jedburgh, in Scotland.

This gentleman being a bank agent, had no doubt sensibly felt the importance of having the means of transmitting, from one town to another, bankers' parcels with perfect safety. With this view he introduces against the end of the bolt a circular stop-plate, to prevent the withdrawal of the bolt until the circular plate, which is put in rotation by clock-work, shall have revolved so as to bring a notch opposite the end of the bolt.

Now as this notch can be set at pleasure to any required distance from the end of the bolt, the lock may be secured against being opened by its own or any other key, until any assigned number of hours after it has been locked. As the rate of traveling is known, the box can be secured from robbery until it shall have reached its destination.

When this fastening is used for portable boxes or packages, it must be put in motion, and its motion regulated by springs; but when it is to be applied to closets or safes, the most simple mode of giving motion will be by a descending weight, and of regulation by a pendulum; the actuating weight may then be made to rest upon, and disengage a locking-bar, in connection with the bolt of the lock, at any assigned number of hours after the fastening has been effected.

In this case all that is necessary is to cause the weight to descend down a vertical scale, divided into hours, and to raise it to any assigned number when the door is locked. A still further security is obtained by the locking-bar itself being prevented from being disengaged by any pressure, except by the descent of the weight, which is made to come, in its descent, into contact with an inclined projection from the lower end of the hour scale, sending it back and disengaging the locking-bar from a notch therein.

BARNARD’S LOCK, Patent dated May 23, 1831.

The specification states this invention to consist, “First, in having the handle which moves the spring-catch fixed to a separate lever or crank, acting upon the arm which projects from the catch, but distinct from it, by which means the said arm may always be of the same length, however thick the door is.

Secondly, in placing the spring which acts upon the catch, at the front part of it, and fastened to the plate which is fixed to the front edge of the door, by which position of the spring I am enabled to use a much longer, and consequently a much more pliant spring.

And, lastly, in a small plate of metal cast upon the key so as to get the exact impression from it, and then, brazed on to the lock-plate to form the keyhole, whereby the pattern of the key is so exactly formed in the keyhole, that it would be very difficult afterwards to make any other key to fit the same hole, and which is, therefore, a very great additional safeguard to the lock."

YOUNG’S IMPROVEMENTS, Patent dated July 27, 1831.

The following account of Mr. Young's improvements in locks and latches is copied from *The Repertory of Patent Inventions.* “Here are no fewer than four new kinds of locks, with as many combinations of springs and plates, and levers for security. ‘Security!’ The word is banished from the modern vocabulary: it is to be described only by negations, as complicated and as numerous as Mr. Young's means of attaining it. Mention the word to your banker or your lawyer, or whisper it to your clerk; ask any one of them for a definition, or put the question to yourself in your own chamber and mark the answer.

"The latched door and the unguarded garden, the cornfield without a scare-crow, and warehouse without watch or ward, are emblems of security. Whoever passed by *Coutt’s* after nightfall without feeling the doubt, and jealousy, and uncertainty, and insecurity, which are the undeviating attendants of wealth, steal upon him?”

Napoleon at St. Helena was free in the midst of guards set to keep him in, when compared with his slavery and imprisonment at St. Cloud, among the infinitely more numerous and watchful guards set to keep others out. Emperors and kings, however, must be

careful, and so must subjects of all grades, and Mr. Young will be most acceptable to the old, who love security, for his efforts to make locks lockable and bolts a security.

We have said that Mr. Young has employed four combinations differently to effect this desirable end. The first is exceedingly ingenious. It is called the '*fly-guard lock*,' and the name aptly describes it, for its principal feature is the "fly-guard."

The self-key of the lock, the very key made for the lock, the identical key which was made with the lock, will open it, but no other key will; for if the false key be a hair-breadth thicker or thinner, or taller or shorter, it will move one or more of a series of levers which will throw the fly-guard off its guard, or rather on its guard, for it forces the lock, or the bolt of the lock, out of its position, and then it so acts on the wards that the key (a false one) cannot by any effort force back the bolt.

Not only is the thief disappointed, but the attempt at theft is discovered; and although Othello, speaking of his mistress, 'felt not Cassio's kisses on her lips,' yet the owner of the patent 'fly-guard' will feel, or may *see* the action of the false suitor on his true lock. A ring on which the action fits, and a bell-shaped plate on which another series of levers act, and finally, a pendulum bolt which acts in a manner at once easy, elegant, and secure, are the securities of Mr. Young.

"A fourth invention is to cast in iron the whole process of a lock, staples, and all, and to add a plate of hammered iron. With these precautions, let the devil try to trench on your security. He'll try."

PARSONS' BALANCE-LEVER LOCK, Patent dated December 20, 1832.

The peculiarity of the construction of this lock consists in the levers being detached from the bolt, their center of motion being in the middle. The front end of the hooks of the levers, when the bolt is shot out, are all in one of the semicircular slots of the bolt.

The action is as follows: The key lifts the levers as near the center of motion as possible, and draws the front end of the hooks of the levers away from the bolt, until all the hooks are brought in a true plane with the edge of the main-bolt. The action may be compared to a scale-beam. The bolt cannot be moved

until the levers are at rest, for if either over-lifted or under-lifted the hooks at one or the other end catch in the slots of the main-bolt, and thus prevent its moving.

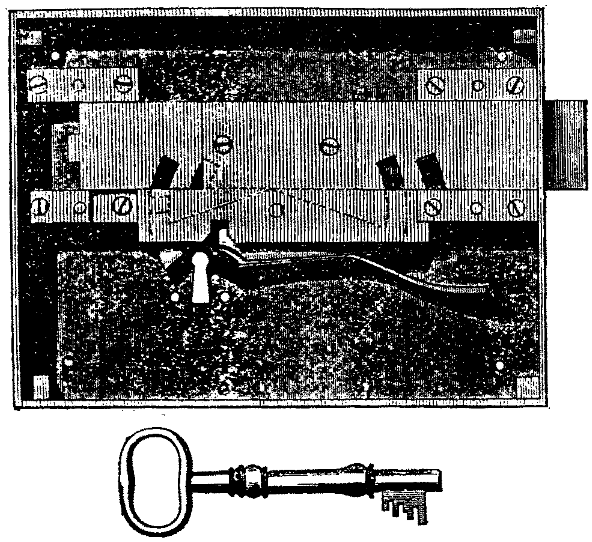

Figure 212. Parsons' Balance-Lever Lock

The above arrangement and the form of the levers and springs allow the levers to be made of very thin metal, so that many of them may be put in one lock without increasing its size to an inconvenient thickness. This is the first lever lock ever made by machinery, and none to the present period have surpassed it in point of correct and finished workmanship. It has continued to command a good sale from the period of its invention to the present time.

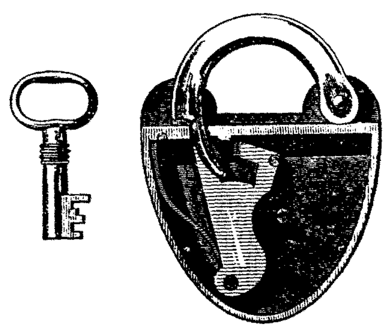

Figure 213.

Mr. Parsons was the inventor of what he calls *lever-tumblers* to padlocks and box-locks, which consists in so constructing the lever-tumblers that their ends form the bolt which locks into the

shackle of the padlock, or the link of the box-lock, as shown in figure 213.

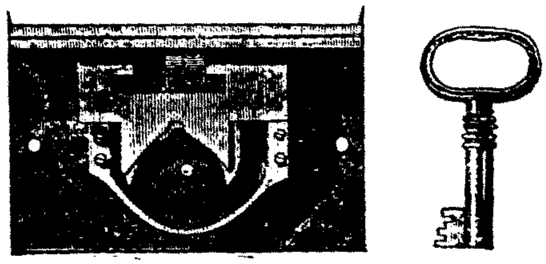

Figure 214.

Figure 214 represents a Parsons' slip-bolt or lever-tumbler lock of this description. This was found in practice very insecure from the circumstance that as there were no springs to the slip-bolts or lever-tumblers, they would shake out of the link, and the lock would thus be opened.

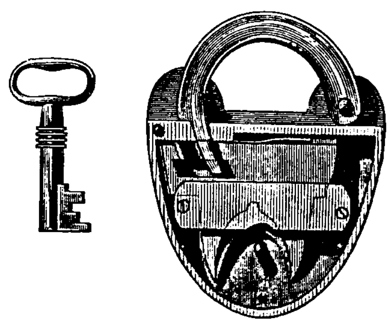

Figure 215.

Figure 215 represents Parsons' second movement for pad or box-locks, which is the same in principle as figure 212, with the addition of a binding or check-spring to each lever. The objection to this was that a blow or a jar would shake the works out of their true position.

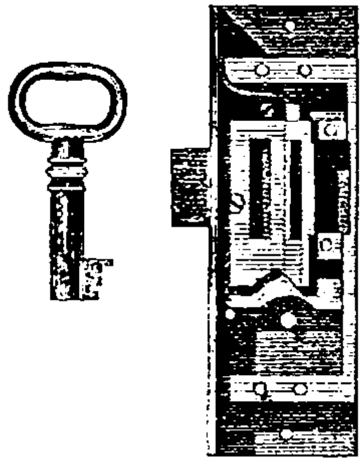

Figure 216.

Figure 216 represents the next improvement by, which the previous faults were corrected, inasmuch as the levers are vertical and slide up by the action of the key, and are forced downwards by the springs acting on their tops.

It must be particularly noticed that Mr. Parsons introduced an improvement into the *two-sided* locks which has never been improved upon or followed by other makers. It consisted in putting into such locks two drill-pins-one on each side of the lock and consequently each set of levers were differently gated, and the keyhole on each side of the lock being in a different position, prevented a direct aperture through the lock.

By this method the same amount of security is obtained in a two-sided lock as in a single-sided one. In all other two-sided locks the security is in the proportion of one to ten between them and one-sided, or the regular locks.

This plan effectively prevents the key-pin from being seen on either side of the door, and consequently is a certain guard against the lock being opened by means of nippers being applied to the end of the key-pin, as was the case in Liverpool and other places a short time ago, by a gang of American thieves, who succeeded in unlocking the doors of the chambers of commercial men, and robbing their pockets or portmanteaus of the convertible contents. We understand that the locks on the chamber doors in France are constructed in the same manner, though of a very inferior description.

Mr. Parsons, whom we rank in the same class with Mr. Bramah for mechanical skill, published a very elaborate table exhibiting the

additional security obtained in any lock by adding one or more levers; showing that each additional lever affords more additional security than many more locks.

He states that, “This table therefore shows the degrees of security attainable by the use of so many levers in one lock; since each change in the arrangement or place of any one of the levers would require a new key, independently of the alteration which might be made in any of their forms.

By this table also a comparison may very readily be made of the security of any two locks, each containing a different number of levers, as is in its last column, between locks with eight levers and every other lock wherein are from nine to twenty-six levers.

And let it not be forgotten that each of these large lever locks is equal; and, inasmuch as it may be better made and stronger, is superior to eight locks with seven levers or guards in each; to 56 locks with six in each; to 336 locks with five in each; and to 1,680 locks with four in each; and that one lock containing four levers or bolts is equal to four locks which contain only three levers or bolts in each; and to 12 of the best two-tumbler Barron's locks; whilst the common locks, with wards and a tumbler, which any pick-lock can remove from the bolt with ease, are worse than useless, as being only deceptive and soon out of order; the usual remedy for which is a removal of the wards by a locksmith, when the lock may be unlocked by any key.

This is a change or *permutation* lock of a peculiar construction, and was designed to afford immediately available protection against the danger of a key being lost or misused. The invention consists in introducing moveable supports or props between the levers which intercept the motion of the bolt and the levers upon which the key acts, which moveable supports are capable of adjustment, for the purpose of requiring longer or shorter bits to the key, according to the position of the said moveable supports.

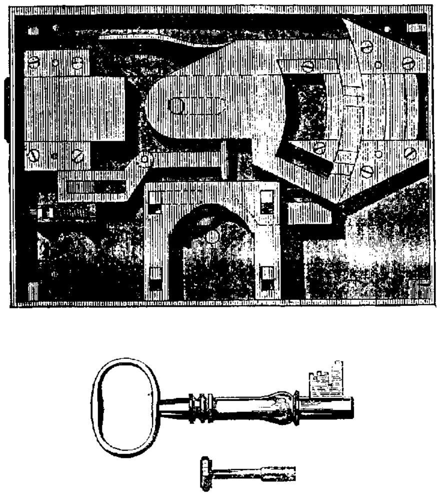

Figure 217. Parsons' Change Lock

The bits of the keys can be adjusted at pleasure to suit the situation of the moveable supports. The action is adjusted by means of the small screw-key shown in the cut, which works on a screw through the selvage or fore-end of the lock, and so moves backwards or forwards the slide, to the arm of which are connected the moveable supports. This adjusting screw changes the position, but not the relative positions of the levers, so that the same difference in the steps of the key must be retained, the change being made only in the length of the bits. The number of changes for each lock is very limited.

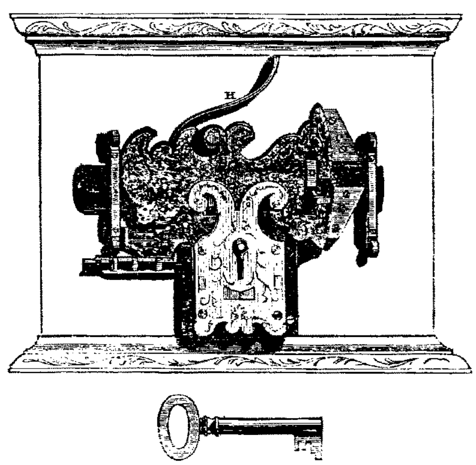

Figure 218. Parsons' Change Lock
(From Aubin's Lock Trophy.)

Figure 218 represents a modification of the change lock, in which the first tier of levers, as soon as the key begins to turn

round, shuts up the keyhole by sliding one lever over another, which effectively prevents any other instrument besides the key being put in.

It answers the same purpose as the curtain in other locks. *A* is the bolt; *B* the levers; *c c* the crescent; *D* the stump of the bolt ; *E* the regulating setscrew; *F* an opening in the cap to show the action of the levers in closing up the keyhole; *i* the slide, to which is attached the supports *G*; *H* the spring.

This is the first permutation or change lock patented in England, but that it had been invented previously is apparent from the circumstance of several old locks having been seen in which this principle was adopted.

MACKINNON'S PERMUTATION LOCK, invented about 1835.

The object of the present invention is two-fold to enable any person to **change(497)** at will the *pattern* or arrangement of the moveable parts in his lock and key, or to keep his key, except when actually in use, in such a state as to render it unavailing to any one but himself.

The bit of the key is composed of one piece marked a in figure 219, which acts on the bolt, and of as many other pieces, *1, 2, 3, 4, 5*, as there are levers in the lock; the pieces of the bit and their corresponding levers being stamped with the same numbers. That part of the stem of the key which carries the bit is not cylindrical but wedge-shaped, as shown at *b* (figure 219), which is an end view of it, with the piece *o* in its place.

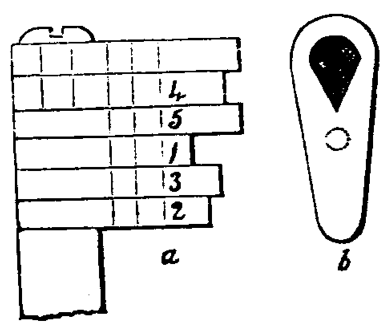

Figure 219.

The pieces composing the bit are thus prevented from moving round on the stem, and are until further secured from shake by means of a pin fixed to the underside of *a*, as shown by the dotted circle

in figure 219, *b,* and which passes through the lever-bits *5* to *1.* The piece *a* is fixed in its place by a small screw, as shown in the cut *b.*

It is almost needless to remark, that if the owner changes the order of the pieces composing the bit, he must change also, in exact correspondence, the order of the levers within the lock. It may sometimes be advisable to do this, when suspicion exists that a copy of the key has been obtained; and it might also in come circumstances be desirable to keep the key with its parts purposely misplaced, in order to foil any surreptitious attempts to open the lock even with its own key.

In figure 220, which represents part of the lock, *a a* is the lever No. *1, b* is an edge-view of a broad spring which acts on all the levers at once, depressing them after the four-sided stud of the bolt has passed, by the action of the key, from one notch in the lever to the other.

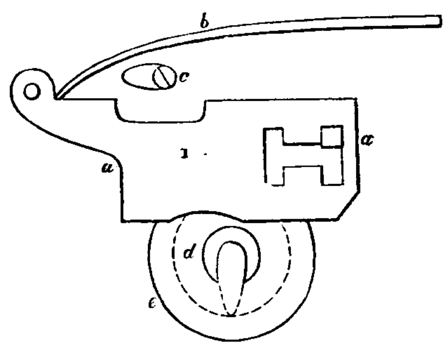

Figure 220.

It is evident that the relative position of the levers cannot be conveniently changed so long as this strong spring continues to act on them; but by applying a turn screw at *c*, and thus raising the button attached to it, the pressure of the spring is relieved, and then the levers may be displaced without any difficulty.

A collar or split-pipe *d* projects from a circular plate *e*, closely clipping the whole bit of the key, and turning round with it when in use. This prevents any of the pieces of which the bit is composed from being strained by any stiffness in the bolt or levers, or by any accidental obstruction.

Dr. ANDREWS' (America) LOCK, invented about 1835.

One of the principal constructions adopted in America a few years back for bank locks is that of Dr. Andrews, of Perth Amboy, in New Jersey. It was up to that time (1841) that it was believed that the best locks, both of England and America, were proof against any attempts at picking derived from knowledge obtained by inspection through the keyhole; but there still remained the danger that the sight of the true key, or the possession thereof, for only a few minutes, would enable a dishonest person produce a duplicate.

It was to contend against this difficulty that Dr. Andrews directed his attention; and he sought to obtain the desired object by constructing a lock, the interior mechanism of which could be **changed(498)** at pleasure. The lock of his invention is furnished with a series of tumblers and a detector. The tumblers are susceptible of being arranged in any desired order; and the key has moveable bits, which can be arranged so as to correspond with the tumblers. When the lock is fixed in its place, no change can be made in the tumblers, and consequently only one arrangement of the bits of the key will suit for the shooting and withdrawing of the bolt.

The owner can, however, before the fixing of the bolt, adopt any arrangement of tumblers and bits that he may choose. But though the tumblers cannot be actually rearranged in any new order within the lock while the latter is fixed, yet by an ingenious contrivance the tumblers can be so acted upon as to render the lock practically different from its former self.

The purchaser receives with his lock a series of small steel rings, each ring corresponds in thickness with the thickness of some one of the bits of the key; so that, by suitable adjustment, any one of the bits may be removed from the key, and a ring be substituted in its place. The effect of this substitution is that the particular tumbler which corresponds with the ring is not raised by it; it is drawn out with the bolt, as if it were part of the bolt itself.

Supposing the lock to be locked by this means, the original key would not now unlock it; for one of the tumblers has now been displaced, and can only be readjusted by the same ring, which displaced it.

If an attempt be made to open the lock by the original key, or by the key in its original adjustment, a detector is set in action,

which indicates that a false key or other instrument has been put into the lock. One, or more than one of the bits may be removed from the key, and rings be substituted, and consequently one or more of the tumblers may be disturbed in this peculiar way; so that the lock may change its character in all those permutating varieties which are so observable in most, "safety locks."

The shape of the tumblers is, of course, such as to facilitate this action; they have each an elongated slot, and also two notches. When a tumbler is raised by one of the bits of the key, one of the notches closes around a stump fitted into the case of the lock, and prevents the tumbler from being moved onward with the bolt; but when a ring has been substituted for a bit on the key, the tumbler cannot be raised at all; it is carried onward by a stump on the bolt.

Dr. Andrews is also the inventor of a lock that he terms the snail-wheel lock. A series of revolving discs, or wheels, taking the place of the tumblers, are mounted on a central-pin, on which the pipe of the key is inserted. Each disc has a piece cut out of it, into which the bit of the key enters, and, in turning round, moves the discs according to the various lengths of the steps on the key.

On the outer edge of each disc is a notch, and by the turning of the key all these **notches(499)** are brought into a line, so that a moveable tongue, or toggle, attached to the bolt, falls into the notches. The key is then turned the reverse way, by which means the bolt is projected."

MEIGHAN'S ALARUM LOCK, invented about 1836.

Among other contrivances for preventing locks from being surreptitiously opened, it has been proposed to connect the bolt with a bell, so that, on withdrawing the bolt, a spring shall be released, by means of which the bell shall be made to sound. The use of such a contrivance is in its application to street doors, that no persons may come in from without, or go out from within, unknown by the master of the house.

The former condition is fulfilled in a very simple way, by attaching a bell on a long vibrating string to the upper part of the door, as is actually practiced in many shops; but this contrivance will not answer the second condition, since a person within the house may muffle the bell before opening the door.

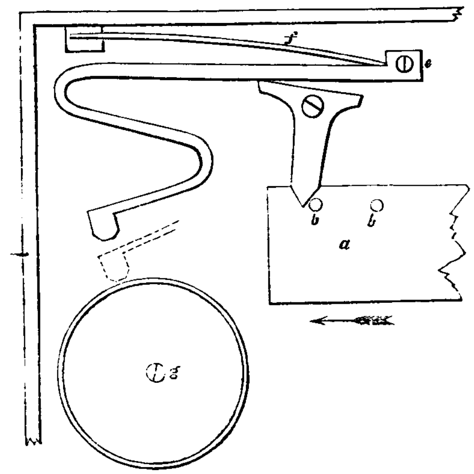

Figure 221. Meighan's Alarum Lock

Within Mr. Meighan's lock, the bell is placed within the lock itself and is, therefore, not to become at except by taking off the lock.

In figure 221, a represents the tail of the bolt in the act of unlocking, and moving, therefore, in the direction of the arrow. Two or more studs, *b b,* are placed on the bolt, one of which is shown pressing against the point of the tumbler *c,* and thus elevating the hammer *d:* this latter is attached to a crooked arm, which turns on the pin *e,* and is pressed upon by the spring *f,* which, when the stud has passed the point of the tumbler, throws down the hammer violently against the bell *g.* This notice will be repeated during the act of shooting the bolt, as many times as there are studs placed on the bolt in a position capable of acting on the tumbler.

This is the first of a number of locks invented at various periods, which are more curious than useful; for which reason none have ever come into general use.

MARR'S LOCK, **invented about 1836.**

This lock is constructed with a small bolt working at right angles through two studs in the main-bolt. If the levers are over-lifted, a small hook on the upper end of the small bolt is forced onto a stump fixed in the plate of the lock by a spring, which retains it. To release the small bolt the main bolt has to be shot a second time, in the same manner as Chubb's, to release the detector.

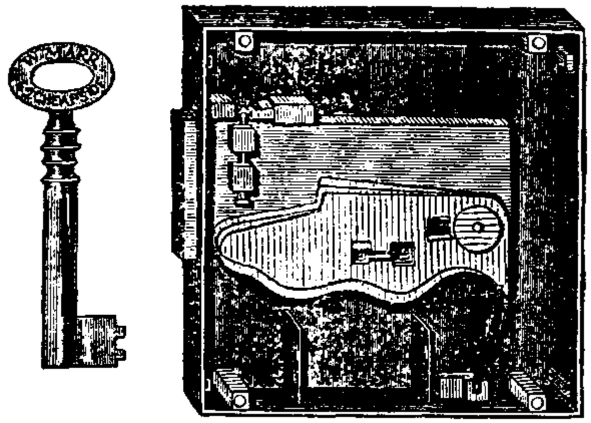

Figure 222. Marr's Detector Lock

THOMPSON'S (SALLY) LOCK, Patent dated November 13th, 1838.

The additional security sought to be obtained in the construction of this lock consists in the setting in motion of an alarm before any key can be introduced into the lock, or before the bolt can be withdrawn. This is accomplished, first, by placing before the keyhole a plate, forming a shutter to the keyhole, to be removed by being slid away, or by being turned on an axis before the key can be introduced into the lock. The shutter shall be in communication with an alarum, situated either within the lock or contiguous to it, or in a room or place to which the motion may be conveyed.

Secondly, it shall operate by forming a communication from the bolt of a lock to a sounding body, so that the motion of the bolt in being withdrawn shall cause a sound, or a succession of sounds, to be given at such place, within practicable distance, as the proprietor of the lock shall determine upon.

The principles of the invention admit of being carried into effect according to the local and other circumstances, in a great variety of forms and modifications. We believe this is the only invention in connection with locks and keys which can claim the honor of having been patented by a female.

SANDERS' LOCK, Patent dated June 12, 1839.

The peculiarity of the construction of this lock consists in attaching the levers to the main bolt, which, in the act of locking and unlocking, travel with it; hence called the "*traversing lever*" lock. It is simply Cornthwaite's lock

reversed. The construction of this lock has been applied principally to dead and stock locks, large quantities of which have been manufactured and sold by Messrs. Carpenter and Tildesley, of Willenhall.

NETTLEFOLD'S LOCK, invented and patented by John Charles Schwieso, July 20, 1839.

The peculiar feature of Nettlefold's lock was that as the bolt was shot out by the key, two teeth, or quadrants, were projected from the sides of the bolt, which took a firm hold of the plate fixed on the door or edge. It was much used for sliding doors, and was found to answer exceedingly well.

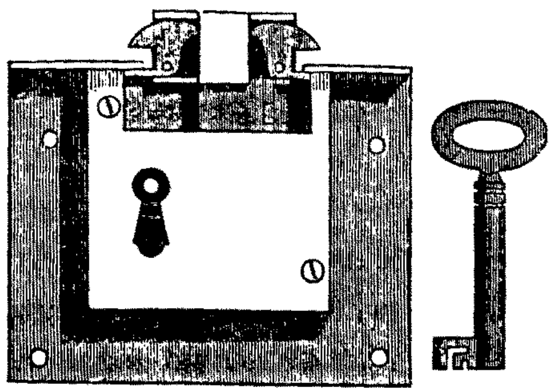

Figure 223. Nettlefold's Lock

The same peculiar movement had also been applied to many other locks, by different makers under the authority of licenses from Mr. Nettlefold."

GERISH'S IMPROVEMENTS IN LOCKS AND KEYS, Patent dated February 27th, 1840.

The Patentee observes that in large doors, where great strength and security are required, it is necessary to have a lock of corresponding size, the key of which is large and heavy, and therefore inconvenient for carrying about. To obviate this, he makes a knob or handle perform the office of a key and throw the bolts.

A lock contained within the knob, acted upon by a very small and portable key, has a forked bolt which locks into the escutcheon, and so renders the knob or handle and the bolts immovable. The patentee also claims the method of throwing a bolt out from the

escutcheon into the knob, and so producing the same effect. Claim is not made to any particular arrangement of lock: in the specification a common tumbler lock is adapted to the purpose.

The difficulty which this benevolent patentee has undertaken to remedy has no existence but in his own imagination. It must be pretty well known to most of our readers that the iron doors of strong rooms, the doors of large iron safes, etc. have long been fitted with knobs performing the office of a key, and throwing from four to ten, or even more bolts; such knob being secured by a small Bramah or other lock, fitted with the most portable keys, which threw a bolt into the arm of the large lock, thereby setting fast the bolts, knob and all. The small lock in this case is placed within the door, and is inaccessible; whereas, if situated in the knob, it is only to saw open or knockoff the knob, and all security is gone.

The next claim is for a mortise latch, contained within a cylindrical metal tube. The bolt, which is also cylindrical, lays along the tube, and is squared and turned up at the end, and a rack cut on its underside. A pinion or sector on the spindle or axis of the knobs turns back the bolt, which is urged forward by a spiral wire-spring coiled around it.

This latch may be secured by a lock in the handles, as before described. As regards originality, this contrivance is no better off than the former; the object is decidedly a good one, viz., to avoid cutting away the wood to so great an extent as is necessary for the usual run of mortise locks; to let in this lock it is only required to sink a circular hole with a center-bit to the proper depth.

Locks of this description, but infinitely superior in arrangement to the foregoing, have been made and used some years, invented, we believe, by Sir John Robinson, secretary to the Royal Society of Edinburgh.

The next *improvement* is in the construction of tumbler locks, with keys having four or more projecting “nibs” placed around the pipe of the key. In lieu of Barron's plan of several steps on one bit, this patentee adopts a separate “bib” for each tumbler, the advantage of which is not very apparent. A little extra trouble in making the lock and key, but no additional security will be obtained.

The claims set forth are, First, the application of a lock and

key to a knob or handle of a lock to secure the same, as herein described. Secondly, the mode of constructing a lock or other such like fastening, by combining a bolt, spring, and pinion, or tooth sector. Thirdly, the mode of constructing a key for locks and other such fastenings by having a series of nibs or projections around the axis of the key, as described.

WILLIAMS' LOCK, Patent dated March 20, 1840.

This lock, like Stansbury's, is a modification of the Egyptian lock. It is constructed with a series of pins, which reach through and are flush with the cap, and are pressed to their places by a key like a comb or rake-head, with teeth of irregular lengths.

On the inner end of each pin is a flat piece of steel, in which is cut a notch that allows the bolt to pass, when all the notches are brought in a line by the key. But as wither one or all of the pins can be pushed too far, they are what is termed "double-acting', and consequently appear to add much to the security of the lock. On the pins being pushed down by the key to their respective positions, the bolt is set at liberty, and is moved backwards and forwards by two springs, one of which is made strong enough to overcome the resistance of the other during the action of locking, and is forced back by the key to allow the weaker spring to act in unlocking. From this latter construction it would appear that its inventor had some idea of picking a lock by applying a pressure to the bolt.

There are several objections to this lock coming into general use. The size of the key, and having to change ends to lock and unlock, makes it both inconvenient and undesirable; and also the liability of the bolt being held by any bind in the bolt-hole, from the circumstance of the key having no control over it, and the easy manner by which a false key can be fabricated.

Soon after this patent was taken out, a joint-stock company was projected, with a capital of 30,000 Pounds, for the purpose of working it; but although the lowest amount of profit was estimated at 10,300 Pounds per annum, but few of the shares were taken up. The factory that had been established in Wolverhampton for the manufacture of the locks, was, in consequence, soon given up. Williams' Patent Lock Company was the first "joint-stock company" ever established for the manufacture of locks.

PEIRCE'S LOCK, Patent dated May 2nd, 1840.

These locks, which are upon Barron's principle, with numerous tumblers, are furnished with a detector, consisting of a sliding-bolt acted upon by any one or all of the levers. The opposite end of this sliding-bolt is jointed to a small lever, mounted on a suitable axis.

Within a tube, opposite the lower part of the keyhole, a dart, or sharp-edged punch, is placed upon a strong spiral spring; there is a notch on the underside of the dart, in which the detector-lever rests and holds the dart down upon the compressed spring. On attempting to open the lock with any but the original key, one or other of the levers is over-lifted, which, acting on the detector-lever, releases the dart or punch, which flies out through the keyhole, wounding the hand that holds the key. The face of the punch being in the form of a letter or figure, inflicts a wound that for several weeks identifies the aggressor; these locks have therefore been termed identifying detector locks. In order to prevent the accumulation of dirt, &c. within the pipe of the key, a metal stop is fitted so as to work freely within it, being kept flush with the end of the pipe by means of an internal spira spring, which yields to the pin of the lock when in use.

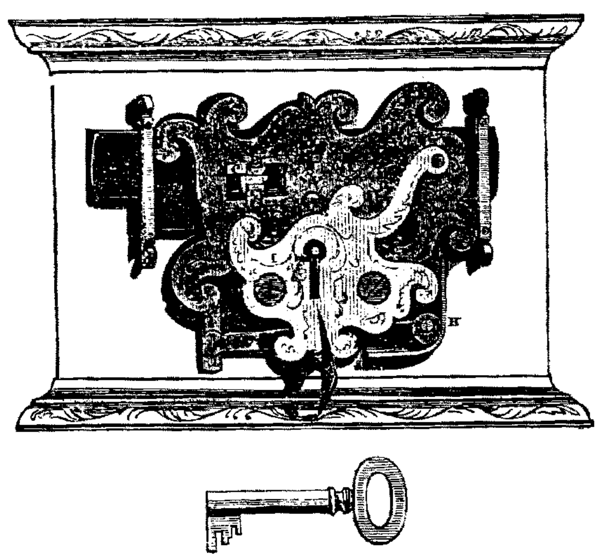

Figure 224. Peirce's Identifying Detector Lock

Figure 224 represents one of these locks as constructed on the base of Aubin's Lock Trophy A is the bolt; B the levels; c the stump of the bolt; D the detector; E F the detecting levers; G the dart.

The construction of this lock appears to have been suggested by the Marquis of Worcester in his Century of Inventions before referred to, where he says that " a lock may be so constructed that if a stranger attempteth to open it, it catches his hand as a trap catcheth a fox; though far from maiming him for life; yet marketh him so, that if once suspected he might easily be detected."

It is said that the inventor himself experienced the efficacy of the detecting apparatus by receiving the steel barb into his own hand, thus showing that, like other detector locks, it would detect on other occasions than when surreptitiously operated upon.

WOLVERSON and RAWLETT ' Lock, Patent dated June 13, 1840.

The improvements claimed in the specification are-first, a new kind of follow for latches; secondly, a peculiar mode of holding down the latch-bolt in latches and locks so as to lessen fiction thirdly, a lock-bolt, the bolt to be bevelled and the bevelled recess for it in the lock-plate to be formed by turning over the metal of the plate, so as to form a tube. They claim also several modes of making bolts work by the hand.

BAILLIE 's LOCK, Patent dated December 23rd, 1840.

The improvements in this lock, as applied in the first place to rim locks, consist in rounding off all the corners so as to prevent their tearing ladies' dresses, and in attaching the lock to the door by means of an angular stud rivetted on its inner side, which slides into a plate staple screwed to the door; the front of the lock being screwed on to the fore edge of the door in the usual manner. The boxstaple is made with a tenon at the back, which is let into the door-frame, and secured by long screws, which pass through the front plate of the staple into the door-frame and through the tenon.

"In the improved lock there is a stop, moved by a small handle on the outside, by turning of which the stop is caused to act against a notch or projectile on the toothed sector that wolks the bolt, and prevents the bolt from being thrown back. For street-door locks this stop has two tongues, which take into the teeth of the pinion that works the bolt, one of the tongues preventing the bolt from being thrown backs the other retaining it when it is thrown back, the tongues being placed so far

asunder that only one can act at a time.

"The claim is to the mode of constructing locks and their fixings or fastenings, whereby the screws passing through locks and staples are dispensed with. Also the mode of applying a temporary stop to locks, as described."

BROOKES LOCK, invented about 1840.

This lock was constructed with a nozzle working inside the Bramah nozzle, so as to shut up the keyhole; or to cut off all communication with the sliders. The key had to perform nearly one revolution before it could be pressed down on to the neck of the sliders to open the lock.

FOSTERS LOCK, invented about 1840.

The peculiarity in the construction of this lock consisted merely in the detector having a different action to the other detector locks in use. When a false key was introduced it was held fast in the lock, or the keyhole was shut up; and in attempting to shift the slide from before the keyhole, the operator was in danger of being struck by a dart when the slide moved. In other respects it was an ordinary lever lock.

PERRY'S IMPROVEMENT FLUSH-BOLT LOCKS introduced about 1840.

This improvement consisted in working the lock with three tumblers; one set in a position at right angles to that of the other two. When the key was forced into the lock it met with a tumbler and a talon on the bolt, by which the bolt was shot up vertically; the key in passing onwards then met with a pair of Barron's tumblers and another talon, and the bolt was thus shot forward horizontally. It is a great improvement in locks constructed on the secure principle, and we believe the only one of its kind. The inventor was upwards of forty years in perfecting it.

BENTON'S LOCK invented about 1840.

The peculiarity in the construction of this lock consists in placing two stumps on the bolt and double-racking the levers. This makes the lock showy, and adds some little to the strength, but not to the security. A specimen lock was exhibited at the Exhibition of Arts and Manufactures held in Wolverhampton in 1840, which obtained the second prize. The wards in this lock

were very nicely fitted, and as a whole it was a well-made lock, which entitled the maker, a working locksmith, to considerable credit, especially as it was his first attempt to produce a lock for competition.

This prize amounted to £1 6f which induces us to remark that such small sums are most inadequate to the purpose of rewarding meritorious inventors The abobe lock, no doubt, cost its maker four or five pounds in producing. The same remark will apply to the premiums offered by the Society of Arts and the result is that the society seldom draws forth an invention of much value.

COPE'S PIANOFORTE LOCK, invented about 1840.

This is a double-bolted pianoforte lock, one bolt of which shoots across and fastens the link, and also drives a crank that shoots a bolt out of the bottom of the lock. Mr. Cope was the inventor of the hardened steel nozzle for Bramah locks, and steel caps for various other kinds of locks, to prevent drilling into the lock-cases. He also invented the mortise padlock.

HICKIN'S CIRCULAR ESCUTCHEON LOCK, invented about 1840.

This neat and simple invention consists of a circular escutcheon for placing before the keyholes of iron safes, and constructed with a lock in the moveable part, which latter opens and shuts similar to the case of a watch, and requires but a very small key. Figure 37, page 55, represents a slide-escuteheon constructed on a similar principle and for the same purpose. Either kind is very useful and convenient where it is desirable to protect a keyhole from observation or prying curiosity.

WAKEMAN'S IMPROVEMENTS IN LOCKS AND ESCUTCHEONS, introduced about 1840.

One improvement consists in making locks with triple drill-pins. On the face of a nozzle fixed on the cap of the lock are seen the ends of three drill-pills, upon which the key formed to fit them passes into a chamber; it is then turned round to a right angle and forced into the interior of the lock, where either of the two bits meeting with the talon of the bolt and common tumbler shoots the bolt. It is a very simple, ingenious, and novel contrivance, and we believe the only one of its kind.

Wakeman improved the changeable letter lock by introducing false notches inside the outer rings; also by cutting a series of teeth

that work into a screw inside one of the rings, so that in attempting to open the lock by binding, this screw comes into action and binds all the rings, and at once prevents the true notches or openings being discovered. When the true position is found on the rings that are to move, the one that is in connection with the screw is turned round and opens the shackle. We consider this is one of the most important improvements ever introduced into the changeable letter lock.

He is also the inventor of the vertical letter locks, with three different actions. First, with the shackle to draw out; secondly, with the usual joint; and, thirdly, with the swivel-joit shackle. He also improved and simplified the various kinds of latches; and his sash-fasteners for utility and security are surpassed by none.

It is supposed this inventor was the first to abandon the ears on padlocks, by making them round with the shackle to pull up and turn round on a swivel-joint He made others to work without a key on the secret principle. His escutcheons were also made on the secret principle, and so contrived that no one could open them without a knowledge of the secret (**note**)(500).

DUCE (Junior's) LOCK, invented 1040, Patent dated May 24, 1842.

This is a lock with a quadruple motion, and was exhibited for competition with other locks at the Exhibition of Arts and Manufactures held at Wolverhampton in 1840, and obtained the principal prize. The action of the lock is as follows: One tumbler is drawn towards the key, another is driven backwards, while one lever works up and passes through a slot in the main-bolt, and another is pressed down, which also passes through a slot in the main-bolt. This motion is both beautiful and very secure, but as the lock comprises so many limbs it is expensive to make. The patented lock contained this additional improvement, viz., an adjusting-spindle when used for doors (**note**)(501). The peculiarity consisted in worming the edges of a square.

After the patent was sealed, Mr. Duce made these locks with only two motions. A tumbler under the bolt is gated into a slot cut to receive it, while a lever is gated to work up through a slot in a stud fixed upon the main-bolt, and moving with it. This lock is simple and tolerably secure, and being cheap has had an excellent run for many years.

It is supposed that this inventor was the first who made locks to

fire off a pistol to give an alarm if any of the levers in the lock were overlifted. He also invented the diamond detector lock. The detector is fixed to the main-bolt, and works upon a stiff joint; if the levers are overlifted it blocks the main-bolt against a stump fixed in the lockplate, and prevents the bolt from being withdrawn. In other respects it is an ordinary lever lock. This is an excellent movement, being simple, effective, secure, and cheap. He was also the inventor of the one-horned follow for locks, which works in a v-formed latch-tail to prevent friction. He also improved the details of mortise locks, and constructed them narrower the usual kind.

Mr. Duce, jr., is one of a very few master lock manufacturers who work at the vice, and he is considered an exquisite workman. He constructed a series of beautiful and interesting specimens of locks for the Great Exhibition of 1851, but from some cause declined to send them. He also invented a beautiful machine for splitting sheet-brass for the purpose of being made into springs for locks.

TILDESLEY and SANDERS LOCK Patent dated March 29 1841.

The first improvement consists in a mode of constructing the sliding-bolt of locks. The bolt in this case consists of a sliding-plate, with four levers and their springs, which moves upon a pin or stud, and carries in its front end an axis, upon which the levers are mounted. The other ends of the levels are provided with slots or openings, through which the pin protrudes, and passes when the bolt is moved by its proper key. But should a false key be introduced the openings in the levers will not coincide with the path of the pin, and the bolt will therefore remain immoveable. A detector is also shown as applied to this arrangement, by which the introduction of a false key is indicated.

The second improvement consists in the application of sliding-levers to the sliding-bolts of locks. A bolt of the ordinary construction has a portion of its upper part, near its middle, removed to make room for a projection affixed to the lock-case. This projection passes through a vertical slit formed in each of three vertical levers; there is a fourth, or bolt-lever, connected to the bolt and moving with it. In each of the extra levers there is a horizontal slot, through which a pin on the lock-lever enters, and allows the bolt to be slid back by the key, when it has brought all the levers into their proper positions. The extra levers have a vertical movement only, but

the lock-lever slides up and down a pin affixed to the bolt, and also follows the horizontal movement of the bolt, being contained in a recess in its side.

The third improvement consists in a peculiarly formed sliding and lever catch-bolt, suitable for drawer or other locks. This bolt is composed of a sliding-plate and three levers, which move on an axis affixed to the lower end of the plate. The levers have each tow notches near the top (one in each edge), and are provided with a spring, which gives the requisite movement to the lever while the bolt is being shot. When the bolt is shot, the notches in the levers are level with the face-plate of the lock, on which they catch, and the bolt cannot be withdrawn by any key unless it will cause the levers to range correctly together; for should any one of the levers be moved too far, its opposite notch will catch on the plate and hold the bolt fast.

HANCOCK'S LOCK, Patent dated May 6th, 1841.

The nature of these improvements is shown in their simplest form as applied to a cabinet or drawer lock. A round pin or nozzle projects form the front plate of the lock, through the centre of which a spiral channel runs from the end to end and forms the keyhole. The key consists of a single thread of a screw stripped from its axis (similar to a corkscrew), which is made to correspond exactly with the spiral channel. On the key being inserted in the keyhole, and turned round till its point reaches the inner end of the spiral channel, it there presses upon the heel of the bolt and unlocks it. On turning the key in the reverse direction, a strong spring throws up the bolt again. The point of the spiral key, when once passed through the spiral keyhole, forms a lever by which the bolt of the lock may be effectively combined with any of the known combinations of wards, guards, tumblers, or other contrivances for affording increased security.

These improvements, the patentee states, are also applicalbe to taps or cocks.

STRONG'S LOCK, Patent dated September 28th, 1841.

The construction of this lock is of a very complicated character, without affording any additional security. The specification, with drawings, is printed at length in the Repertory of Patent Inventions, from which we extract the patentee's various claims: "First, in the combination of a series of two or more tumblers

attached to the bolt of a lock and one to another, each tumbler of the series, near the end opposite to the fulcrum of that preceding tumbler, the first of the series having its fulcrum in the tail-plate or thin part of the sliding-bolt; thus the fulcrum of the tumblers are alternately placed near the opposite ends of the tail-plate, and consequently the alternate tumblers rise the one to the right hand and the other to the left, where the lock is held up in a vertical position, whereby a great complication of checks against the operation of a false key is obtained form a few tumblers.

"Secondly, in attaching a secondary-bolt sliding transversely in the main-bolt of a lock, and acting against an abutment, to form a detent in addition to the complicated effect of the alternating-tumblers described as the first part of my improvements; this transverse-bolt being to be drawn back by one of the tumblers before the main-bolt can be withdrawn."

"Thirdly, in the combination of the alternating-tumblers with a secondary-bolt attached to the lock-plate, and shooting into a noch in the main-bolt to prevent its being drawn back previous to the withdrawal of the bolt."

"Fourthly, in adding to the combination of alternating-tumblers a detecting-tumbler connected with the secondary-bolt above described under the second part of my improvements, which detecting tumbler on being lifted too high by a false key is there detained by a spring-catch until realeased by the true key."

"Fifthly, in the combination of a hooked catch-piece, with several tumblers acting on one common fulcrum, the whole of the tumblers constituting a substitute for the bolt, whereby a greater number of tumblers of a given thickness may be introduced into a thin lock than when the catch-piece is pierced through in the manner of a staple."

"Sixthly, in the application of a pair of links, one hinged to each side of the sliding-bolt of a spring-latch, each link terminated at the end opposite to the hinge by a hook catching on upon the follower, whereby the followers, whether turning right or left, act with very little friction withdrawing the bolt."

"Seventhly, in the formation of a hinge by casting alone in parts of the lock in which the motion on the joint is but small, for which purpose a notch is cast in one of the pieces of the

hinge of the form of about three-fourths of a hollow cylinder, into which notch a cylindrical protuberance or knuckle, cast with the other piece of the hinge, fits and turns in a small arc of a circle, such a hinge being peculiarly applicable to the joining of the links to the sliding-bolt of the spring-latch mentioned under the sixth head of my improvements."

"Eighth and lastly, in the application of a forked connecting-piece between the followers. and a lifting-latch for the purpose of communicating the motion of the followers to the latch with very little friction."

The above application of a jointed tail-piece to latches, where the follow-horn works, is an excellent plan for preventing friction.

Strong was also the inventor of the self-acting padlock-shackle. It is so constructed that when the key moves back the bolt, the shackle flies up; and to lock, it merely requires the shackle to be pressed down. The action and fastening is near the joint end of the shackle. Some of his shackles fastened in the centre.

NEWELL'S (American) LOCK, invented in 1841. English Patent dated April 15th, 1851.

This lock, commonly known as the American Parautoptic lock was invented by Mr. Newell of the firm of Day and Newell, of New York, in 1841, but was scarcely known in England till the opening of the Great Exhibition of 1851, in which year it was patented in this country, with the improvements introduced since the year 1841.

The specification states that "The object of the present improvements is the constructing of locks in such manner that the interior arrangements, or the combination of the internal moveable parts, may be changed at pleasure according to the form given to, or change made in, the key, without the necessity of arranging the moveable parts of the lock by hand, or removing the lock or any part thereof from the door. In locks constructed on this plan the key may be altered at pleasure; and the act of locking, or throwing out the bolt of the lock, produces the particular arrangement of the internal parts which corresponds to that of the key for the time being.

While the same is locked, this form is retained until the lock is unlocked or the bolt withdrawn, upon which the internal moveable

parts return to their original position with reference to each other; but these parts cannot be made to assume or be brought back to their original position, except by a key of the precise form and dimensions as the key by which they were made to assume such arrangement in the act of locking.

The key is changeable at pleasure, and the lock receives a special form in the act of locking according to the key employed, and retains that form until in the act of unlocking by the same key it resumes its original or unlocked stated. The lock is again changeable at pleasure, simply by altering the arrangement of the moveable bits of the key; and the key may be changed to any one of the forms within the number of permutations of which the parts are susceptible."

The "claims" put forth under this patent are the following:

1. The constructing, by means of a first and secondary series of slides or tumblers, of a changeable lock, in which the particular form or arrangement of parts of the lock, imparted by the key to the first and secondary series of slides or tumblers, is retained by a cramp-plate.

2. The constructing, by means of a first and secondary series of slides or tumblers, of a changeable lock, in which the peculiar form or arrangement of parts of the lock, imparted by the key, is retained by means of a tooth or teeth, and notches on the secondary series of slides or tumblers.

3. The application to locks of a third or intermediate series of slides or tumblers.

4. The application of a dog with a pin overlapping the slide or tumblers for the purpose of holding in the bolt when the lock is locked or unlocked.

5. The application of a dog, operated on by the cap or detector-tumbler, for holding the bolt.

6. The application of a dog, for the purpose of holding the internal slide or tumbler.

7. The application to locks of curtains or rings, turning and working eccentrically to the motion of the key, for preventing access to the internal parts of the lock.

8. The application to locks of a safety-plug or yielding-plate, at the back of the chamber formed by such eccentric revolving-curtain or ring.

9. The application to locks of a strong metallic wall or plate, for the purpose of separating the safety and other parts of the lock from each other, and preventing access to such parts by means of the keyhole.

10. The application to locks of a cap or detective-tumbler, for the purpose of closing the keyhole as the key is turned.

11. The constructing a key by a combination of bits or moveable pieces, with tongues fitted into a groove and held by a screw.

12. The constructing a key having a groove in its shank to receive the detector-tumbler.

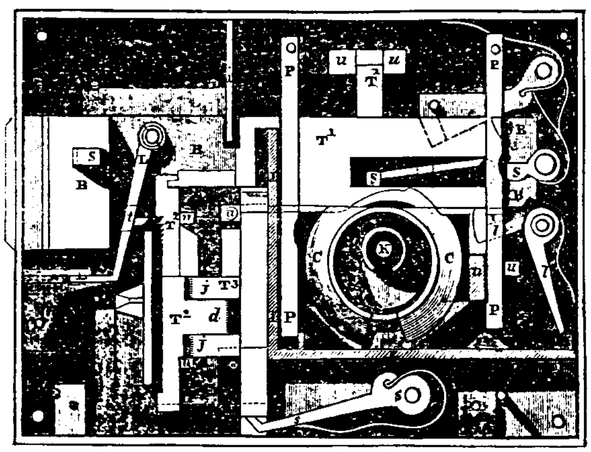

Figure 225. The American Parautoptic Lock, bolt unshot.

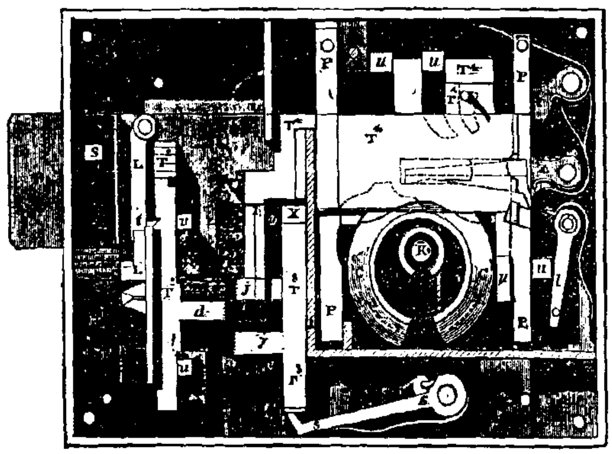

Figure 226. The American Parautoptic Lock, bolt shot.

We shall here copy the description of this lock from Mr. Tomlinson's work before reffered to:

"In figure 225 the lock is represented in its unlocked state, with the cover or top-plate removed; the auxiliary tumbler and the detector-plate are also removed. In figure 226 it is represented as locked, with the cover and the detector-plate also removed, and the auxiliary-tumbler in its place. In these two figures the same letters of reference apply to the same parts, unless otherwise stated."

B B is the bolt; T are the first series of moveable slides or tumblers; s shows the tumbler springs; t2 the secondary series of tumblers; and t3 the third or intermediate series, there latter coming between the first and secondary series; PP are the separating plates between the several members of the first series of tumblers; s1 are the springs for lifting the intermediate tumblers. On each of the secondary tumblers t2 is a series of notches, corresponding in mutual distance with difference in the lengths of the moveable bits of the key.

It thence happens that, when the key is turned in the lock to lock it, each bit raises its proper tumbler, so that some one of those notches shall present itself in front of the tooth t in the dog or lever LL. When the bolt B is projected by the action of the key, it carries with it the secondary tumblers t2, and presses the tooth t into the notches; in so doing it withdraws the tongues d from between the jaws jj of the intermediate tumblers t3, and allows the first and intermediate tumblers to fall to their original position.

By the same movement the secondary tumblers t2 become held in the position given to them by the key, by means of the tooth t being pressed into the several notches, as shown in the closed state of the lock. (Figure 226) Now let us see what results if any attempt be made to open the lock with any arrangement of key but that which it has been locked. In such case the tongues d will abut against the jaws jj, preventing the bolt form being withdrawn; and should an attempt be made to ascertain which tumbler binds and requires to be moved, the intermediate tumbler t3 (which receives the pressure), being behind the iron wall II, which is fixed completely across the lock, prevents the possibility of its being reached through the keyhole.

The first tumblers T are quite detached at the time, thereby making it impossible to ascertain the position of the parts in the inner chamber behind the wall II. K is the drill-pin on which the key fits; and c is a revolving ring or curtain, which turns round with the key, and prevents the possibility of inspecting the interior of the lock through the keyhole. Should, however, this ring be turned to bring the opening upwards, a detector-plate D, (figure 227,) is immediately carried over the keyhole by the motion of a pin p1 upon the auxiliary tumbler t1, which is lifted by the revolution of the ring c, thereby effectually closing the keyhole.

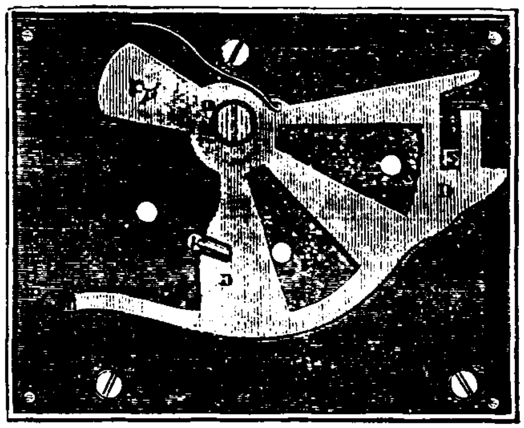

Figure 227. The Detector-plate.

As an additional protection, the bolt is held from being unlocked by the stud or stump s bearing against the detector-plate; and, moreover, the lever ll holds the bolt, when locked, until it is released by the tail of the detector-plate pressing the pin p1. l1 is a lever which hlods the bolt on the upper side, when locked, until it is lifted by the tumblers acting on the pin p1; x are separating-plates between the intermediate tumblers t3; uu1 are the studs for preserving the parallel motion of the different tumblers.

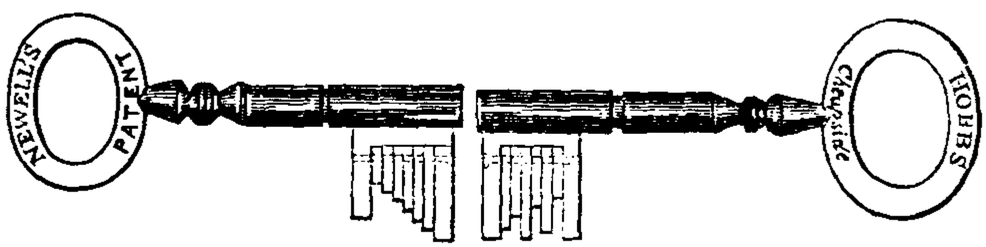

Figure 228

"Figure 228 represents the key in two different forms, or with the bits differently arranged. Either form will lock the lock , but the other will not then unlock it. The end of the key is represented in figure 229, showing the screw which fixes the bits in their places. This bits for a six-bitted key are shown separately in figure 230."

Figure 229

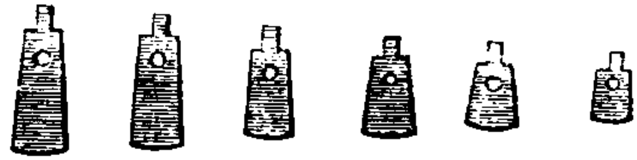

Figure 230

FIELDHOUSE'S IMPROVEMENTS, introduced about 1841.

This inventor was the first to introduce Barron's principle into the construction of the "Banbury" lock. He also introduced into the construction a double drill-pin, that is, fixing a drill-pin on each side of a plate to prevent seeing through the keyhole. The platform or bridge-plate was in connection with springs, so that when the key was forced into the lock, the plate on which the drill-pins were fixed gave was for the key to enter.

ROCK'S IMPROVEMENTS, Patent dated Dec. 29th, 1842.

These improvements consist, first, in a mode of applying friction rollers to the tumblers of tumbler locks.

Secondly, in applying friction rollers to the sliding bolts of back-spring locks, so as to facilitate their movements in the act of locking or unlocking.

Thirdly, in the application of a connecting-link or crank, to ease the friction of locking and unlocking;

Fourthly, in a mode of applying a stop to a sliding-bolt of a lock.

The friction-roller consists of a circular plate or disc, which revolves on a stud fixed to the end of a lever-tumbler, which latter works on a stud fixed in the main-bolt. The lever-tumbler and the friction-roller are kept in their true position by a spring. When the key is placed in the lock, in turning round it comes in contact with the roller, and in the act of rising with the lever-tumbler revolves, and so lessens the friction.

The friction-roller, when applied to the sliding-bolts of locks, is constructed so as to move on an axis affixed to the frame-cheek or case of the lock. In the under part of the bolt are formed two curved recesses, and the key acts on the inclined surface, so as to lift or throw the bolt, and cause it to rise

over the friction-roller, and in such a manner as to cause one of the curved recesses to pass away from the roller, and to bring the other curved recess over the roller. The friction-roller may also be applied to the bolt, and have fixed recesses; and it is not absolutely necessary that the recesses should be used, as the roller may be caused to rise and fall over a check-stop or bar.

THOMAS'S PRISON LOCK, invented about 1842.

This lock, invented by Mr. Thomas, of Birmingham, contains a common tumbler, a bolt, and a brass guard-flap, the latter retained in its position by a spring inserted at the back of the lock. The key in its revolution lifts the guard-flap at the same time that it acts upon the tumbler, and throws the bolt. The lock has also a handle on the outside attached to a trigger, which catches the bolt when shot back by the key in opening the door, and retains it until the handle is touched, which puts the bolt on half-lock.

This contrivance, the object of which is intended to save the time of the turnkeys, places the bolt in such a position, that on closing the door from the inside, the lock can only be opened by the application of the key from the outside. According to the rules of the Pentonville prison, where these locks are used, every prisoner is obliged to touch the handle of the trigger, and so shut himself into his cell. There is nothing very novel in the construction of this lock, neither does it possess any real security, its only recommendation appears to be its cheapness, the price being but ten shillings. It certainly cannot be picked from the inside, as there is no keyhole, and the escape of prisoners from the above prison some months ago was not effected by picking the locks.

AUBIN'S LATCH-BOLT, invented about 1842.

This improvement in the construction of lever-latches consists in placing the latch-bolt at the back of the levers, thus making it almost impossible to reach the bolt by any surreptitious instrument. The key works upon a detached bolt, to which are gated five or more levers, and when the latter are lifted to their true position the detached bolt draws in the latch.

Another important feature in the construction of this latch is, that the latch-bolt works independently of the other limbs of the latch; and, further, as there is a projecting lip or nib on one or more of the levers, the bolt is thereby fastened, so that the

thin piece of steel used by burglars, and inserted between the door and door-frame to force back the latch-bolt is useless, the bolt being fast. On the back of the latch-case is a knob, which releases the lip or nib, and which is used for drawing back the latch-bolt. In some of these latches there is a pin which revolves through the top of the knob and passes in and through the latch-plate, thereby doubly securing the latch-bolt.

The inventor of this useful latch has experienced a serious loss by it; but few have been sold, in consequence of the price (ten shillings) being more than a common one can be had for.

TANN'S LOCK, Patent dated November 25th, 1843.

The patentees state that "The Reliance Guarded Lever Lock has a decided advantage over other lever locks, a new principle being introduced, viz.: the protecting one, two, or more of the levers by a guard which, in addition to all the advantages of the lever-detector locks, presents an entirely new feature, and prevents the possibility of any keys yet made opening it.

"Secondly, The guards are placed on several of the levers, and protect the lever either above or below them, so that even if a false key or pick succeeded in lifting to the proper height all the levers with unprotected fronts, it could not possibly raise the one behind the guarded lever, and the slightest extra lift of the guarded levers at once fixes the detector, and then the proper key only can regulate it."

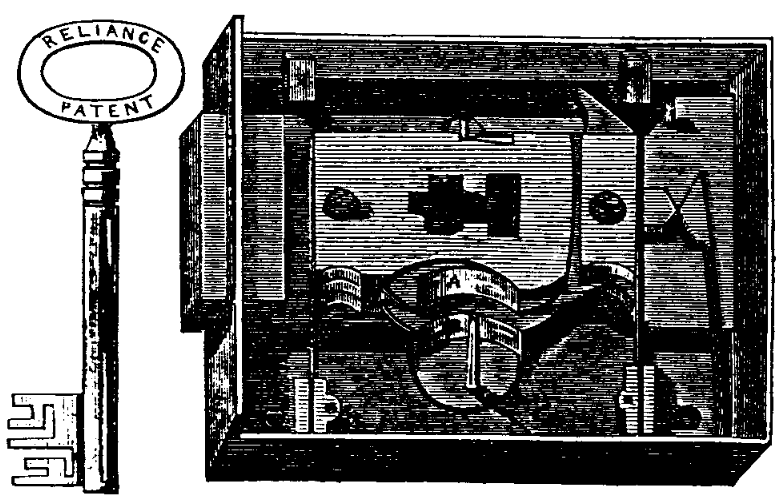

Figure 231. Tann's Reliance Guarded-lever Lock.

These guards are shown at A B, figure 231. The objection to their construction is, that the key-bit being cut to correspond thereto is very much weakened, and is thereby rendered more liable to be broken. The similarity of these "reliance guarded-levers" to the "descending-tumbler" of Somerford's second lock, invented many years before, on a comparison, will be apparent. The detecting apparatus is also identical with that of Richards'.

PITT'S IMPROVEMENT IN LATCH-BOLTS, introduced about 1844.

This improvement consisted in fixing on the latch-bolt a spring and lever, which hooked on to a stump fixed into the follow-horn. When used as a latch the follow would draw in the latch-bolt; and when required to lock, the lever (being balanced or pivotted in the middle) was lifted off by the action of the key, when it would lock, leaving the follow free; the hook-end of the lever would be moved on to another stump, and so fasten the bolt. The other parts of the lock were constructed on the common rim-lock principle.

PICKIN'S IMPROVEMENTS, introduced about 1844.

These improvements were applicable to common door locks, and consisted in drilling a small hole through the lock-case and main-bolt into the door, and at night inserting therein a pin or plug, which held the bolt, so that no key or any instrument whatever could move the bolt till the pin was withdrawn. This is a very simple and effective way of securing an inside lock, no matter upon what principle it may be constructed. The same inventor also introduced flush or secret slips to work into common locks, thereby adding further security to their construction at a trifling outlay.

CHESTERMAN'S IMPROVEMENT, introduced about 1844.

This improvement consisted in the application of curiously constructed levers to locks, so that signal wires could be carried from the internal machanism of lever locks to any required place. Some of these locks had best gun-locks fixed in them, and the action of the gun-lock combined with the levers. The tumbler of the gun-lock projected through the lock-case, to which was fixed at night a lever of about five inches in length, and the signal wire attached to the latter. The lever was then lifted up, which tightened the wire and put the gun-lock on "full cock." The action, therefore, was as follows:

Supposing the door closed and the lock fastened in the ordinary way and left (the key of course being taken out), could any false key or other instrument be forced into the lock, the instant the levers are touched (they being connected with the wire) they would act as a trigger, which would release the action of the gun-lock, thereby bringing down the lever to which was attached the signal wire, and this would set in motion an alarm bell placed in any required distant situation, so that its noise would not be heard by those tampering with the lock.

The signal being thus conveyed, there would be a chance of the thieves being detected on the spot. Window sashes, etc. could all be connected together in the above manner, if desired.

These locks were so expensive to make and fit up that few were sold, and consequently their manufacture has been abandoned.

POOLE'S LOCK, Patent dated December 4th, 1845.

The only peculiarity in the construction of this lock is the key and what the inventor calls the "follower." The screwed stem of this follower passes through a plate fixed inside the lock, and the cylindrical portion of it is screwed into a corresponding recess in the plate, and turns therein, the recess acting as a bearing for the follower.

The arm of the follower enters a notch formed in the bolt, consequently when the follower is turned on its axis of motion the bolt will be moved. Through the centre of the axis of the follower is formed a hole, and at one side a recess; and through this hole a pin passes, there being a cross-head affixed; and this cross-head is formed to fit the recess in the follower; hence, when the cross-head is in the recess, the bolt cannot be moved; and this pin, and consequently the cross-head, can be moved out of the way by means of the key, or by means of a lever constructed in the lock.

The key is formed with a female screw to fit the male screw in the follower; and the interior of the key is so formed that it will come against the pin, and push it back into a proper position to allow the bolt to slide. The bolt is at all times pressed outwards by a spring, and there is another spring which constantly presses the pin into the follower, and therefore the pin will, by its cross-head, retain the bolt from sliding till the pin is moved back; and the key, on being further turned, will receive back the bolt.

When it is desired that the bolt should be free to be acted on by its handle, then the lever before mentioned is to be folded down, by which means, owing to the form of the lever, the pin to which the lever is attached will be moved back by the lever, and as long as the lever is folded down the bolt will be free to be moved. The above improvements may be applied under different arrangements of locks, and the details may be modified.

AUBIN'S SLIDE-STUMP LOCK, invented about 1845.

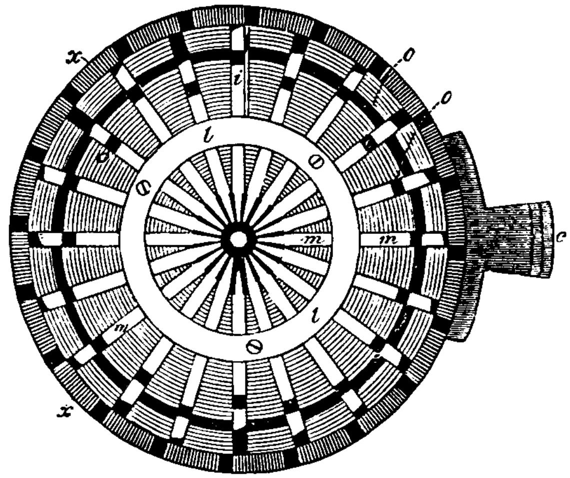
This was intended as an improvement on Marr's lock. The stump, which is usually rivetted to the bolt, was in this lock fixed on a slide which worked in the bolt, and this slide threw out a detecting-bolt or slide at right angles to the other, and held a stump fixed in the plate. The other parts of the lock were constructed on the usual lever principle. It was found very expensive to make, and was consequently abandoned.

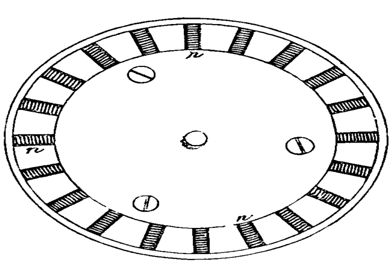
FELLOWES' IMPROVEMENT, introduced about 1845.

This improvement consisted in placing the tumbler and spring upon the main-bolt, which all moved together. The tumbler-stumps were racked or gated into the cap-plate of the lock, thereby simplifying and also adding to the strength of the lock by reducing the number of limbs.

COTTERILL'S LOCK, Patent dated March 25th, 1846.

The construction of this lock, which the inventor calls the "Patent Climax Detector Lock," is on the same principle as Bramah's, except that the sliders, with their springs, are placed in a position at right angles to that of the key, instead of in a position parallel with the key.





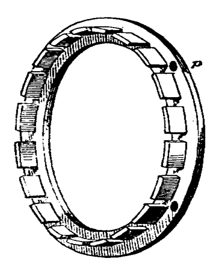


Figure 232.

Figure 232 represents a front view, showing the principle of the lock. Figure 233 is a back view of it. The cylindrical barrel, as shown in figures 232 and 233, contains a number of steel slides mm, (figures 232 and 235,) which move in radiating channels cut in the face of the barrel, and are pressed towards the centre by helical springs, nnn, figure 233, contained therein. A circular groove, oo, is cut in the face of the barrel, and also in the face of the slides, so that when the slides are forced outwards, by pressing the key into the keyhole, a continuous circular channel is formed by the coincidence of each of these with that in the barrel's face.

When the key is withdrawn, each of the slides is forced in different degrees towards the centre, so that their solid portions intercept the groove in the barrel, and in this position the barrel is held fast by a fixed circular ring p, figure 234, fitting in the groove oo, figure 232, and notched on its face so as to embrace each of the slides. The key consists of a cylindrical stem z, figure 235, having a number of inclined grooves cut in its circumference, agreeing with the number of slides in the lock.

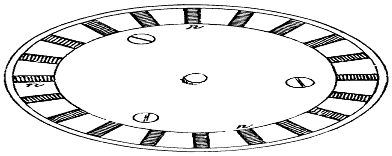

Figure 233.

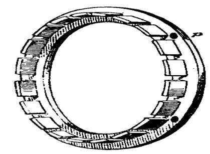

Figure 234.

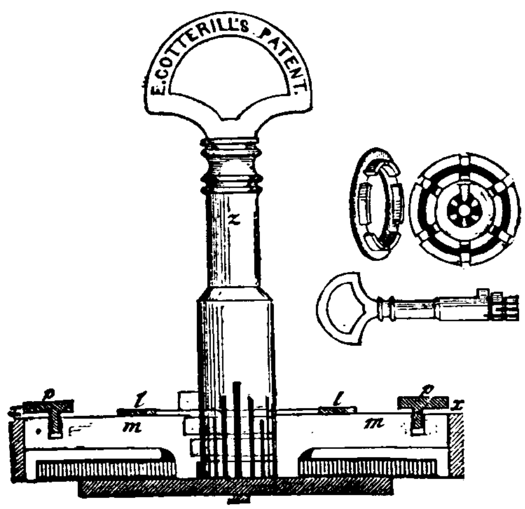
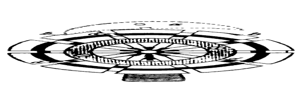
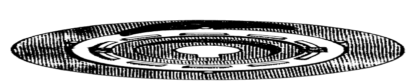
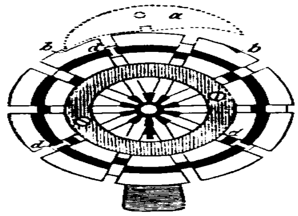
These grooves are cut longitudinally in the barrel of the key, and they vary in depth, slope, and the angle formed by their bottom with the purpose of opening it; the inclined bottom of each groove forces out a slide until the openings in the latter coincide with the notched ring, figure 234, and the barrel may then be turned by the key in either direction.

Should an attempt be made to open the lock with a false key, the slides would be projected too far, and would be retained in that position by a spring-catch or detector i, figure 232, which falls into the groove, so that the true key cannot open the lock until by a peculiar backward movement the detector is disengaged; this detector is not likely to be thrown by accident. x, figures 232 and 235, is an outer ring for the purpose of preventing the slides being acted on separately. e is a thrower which works the lock-bolts underneath the disc, in a case (not shown in the cut) of the usual form. Figures 236 and 237 show another contrivance for increasing the security of the lock.









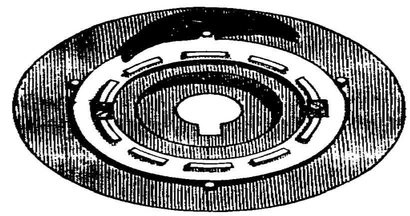


Figure 235.

a
b
b
d
d

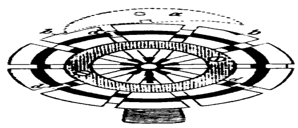

Figure 236.

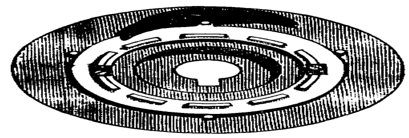

Figure 237

a is a double click, placed to prevent the possibility of a pick-lock acting upon the works, as the slightest strain applied to the lock, in either direction, would instantly oscillate the click and fasten it at b. The notches on the slides at dd will also prevent a strain being put upon the lock, for should an attempt be made to open the lock, the notched slides would come in contact with the circular notched ring, figure 234, and at once lock the action.

The inventor states that "any violent application of an opening instrument of a false key will not affect the works injuriously, owing to the slides being firmly fixed in deep grooves formed in the revolving-barrel, and secured down by a steel ring l, which precludes every approach to the movement by any other means than the legitimate key, from which, owing to its peculiar formation, it is impossible to take an impression, and advantage no other key possesses."

"The slides merely move along the grooves, under cover, and return by the pressure of the helical springs, which are equally distributed around, and these having such a very slight amount of duty to perform, are not liable to set or break; but supposing such an improbable thing could occur, it would not injure the action in the slightest degree, as the security of the lock rests solely on the exact distance the slides are forced from the centre, not in their returning to any particular place, consequently the security of the lock must remain unimpaired, even if the whole of the springs were damaged. Where the slightest friction occurs in the works, a counter one has been provided, in order to prevent derangement; in fact this lock has treble the strength and durability of any lock in the market, and possesses none of their liabilities to get out of order."

The keys are cut by a newly-invented machine, which can be varied whilst working to such an extent, that millions of keys may be cut and yet every one shall differ.

"The locks are all made to the keys, which at once removes the possibility of any but the legitimate keys opening them."

"This lock can be made to shoot any number of bolts in each

direction, and from the peculiarity of the principle gunpowder will not injure or affect the bolts in the slightest degree; neither can any instrument be applied to the key from the outside when the key is left in the door of a chamber inside. This is another peculiar advantage which no other lock possesses."

We may remark that there is nothing peculiar in the keys of this lock being made to lock, as this is the case with all best patent locks, as for instance, a six-lever lock. The key is first stepped as required, and then the levers are gated to it, which is identical with the cutting of the grooves in the slides of Cotterill's lock, after the prepared key has forced them to their true positions.

JONES' (American) LOCK, Patented in America about 1846.

This is a lever lock on the permutation principle, and very complicated. The levers are constructed with false notches, and there is a barrel and curtain combined. We have had lent to us, by Mr. Hobbs, one of these locks, which bears the date 1846, No. 184. It was sold by Mr. Jones to the United States Treasury in 1848. This identical lock Mr. Hobbs picked in 1850.

DE LA FONS' IMPROVEMENTS, Patent dated July 6th, 1846.

In the specification* of this patent various claims are set forth, the principal one being for a revolving or rotating bolt to locks in place of the ordinary straight action. The patentee also claims the use of the barrel and curtain, for the purpose of enabling the key to make an entire revolution, while the bolt made but three-fourths of a turn. The revolving forms a kind of outer ring to, and is acted on by, the curtain. The barrel and curtain, with the key, making a quarter of a turn before they move the bolt; they, of course, make a full turn while the bolt makes but three-quarters of one.

The closing up of the keyholes is spoken of in the specification merely as an incidental advantage gained by the arrangement, and although thus mentioned, was manifestly looked upon by Mr. De la Fons as of little consequence.

The other claim is for such a modification of one of his adoptions of the round bolt, as enables him to make it a tell-tale lock.

From the wording and meaning of the specification we feel

inclined to believe that Mr. De la Fons, at this period, had no real or defined conception of even the advantages supposed to be derived from the use of the combined barrel and curtain.

That Mr. De la Fons has no right to claim the barrel and curtain as his invention will be evident on a reference to the description of Mallet's lock; and we take the opportunity of here stating, that we believe the barrel and curtain combined was invented many years before the date of Mallet's patent (1820), as will be apparent from the following evidence we have obtained on this subject:

Mr. Richard Manning, keymaker, of Wolverhampton, distinctly remembers his step-father, John Roughley, of Cross Green, Coven, near Wolverhampton, maker of fluted keys and revolving barrels for the keys to work in, frequently making locks with the barrel and curtain combined, which he effected by brazing a thin disc of metal on to the top of the barrel. This was sixty years ago.

Mr. Thomas Wright, a locksmith in the employ of Mr. Duce, recollects making locks with the barrel and curtain combined sixty years ago. Mr. Yates used to make locks with the barrel and curtain combined, to order, a dozen at a time, forty years ago. Mr. Duce used to make locks with the barrel and curtain combined thirty-five years ago.

Mr. Thomas Hart, a locksmith in the employ of Mr. James Gibbons, jr., states that he recollects the barrel and curtain combined being used in locks made at Mr. David Evans', Brownlow-street, Drury Lane, London, about the year 1823; and that he used to make them there himself. Mr. Aubin used to make locks with the barrel and curtain combined, two and three at a time, to order. He used a piece of tubing for the barrel, with a thin disc of metal soldered on the top for the curtain, and this construction he states he copied from a very old lock. The last he sold, in quantity, were to a firm in Wolverhampton, January 15, 1845.

It appears that these locks were ordered principally for carpenters' tool-chests, when anything extra was required. That the barrel and curtain combined was also adopted in America previous to the date of this patent is quite evident, from the fact of Mr. Jones' lock containing it.

CHUBB'S QUADRUPLE LOCK, Patent dated December 14th, 1846.

This lock is especially intended for the fastenings of bankers'

and merchants' strong rooms, and other analogous uses. It is called 'The Quadruple Lock' (figure 238), and consists of a combination of four separate and distinct locks in one, all being acted upon at the same time by a single key with four bits. It will be seen in figure 238 that the main-bolts are attached to an eccentric wheel, throwing them each way; and to these bolts ten or twenty bolt-heads may be fitted.

The quadruple lock has six levers in each set, making altogether twenty-four levers, all of which must be acted upon simultaneously, by the motion of the proper key, before the eccentric wheel can be turned; it is thus utterly impossible, from the extensive combinations, for any attempt by a false instrument to succeed in unlocking it.

"As a further security there is a check lock, with a small key, which throws a hard steel-plate over the large keyhole. Thus, in a banking establishment, a confidential clerk may carry the quadruple key, and the principal having the smaller key, can at all times prevent the fire-proof safe or strong room from being opened, unless in his own presence."

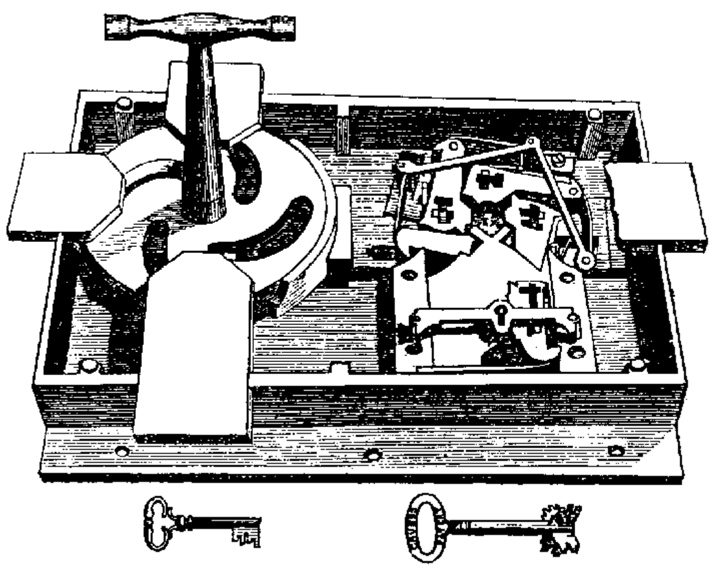

Figure 238. Chubb's Quadruple Lock.

We may observe that there is nothing new in the construction of this lock, as it is identical with the quadruple lock invented by Mr. Duce in 1823.

The use of these quadruple locks, the bolts of which are thrown

by the key, has altogether been superseded by throwing the bolts of such locks with a knob or T handle, and securing them by a small lock; and were it is desired that the principal of an establishment should lock and unlock the safe or strong room, and that the keyhole should be secure from observation, this effected by a slide lock-escutcheon, as shown in figures, 37 and 38.

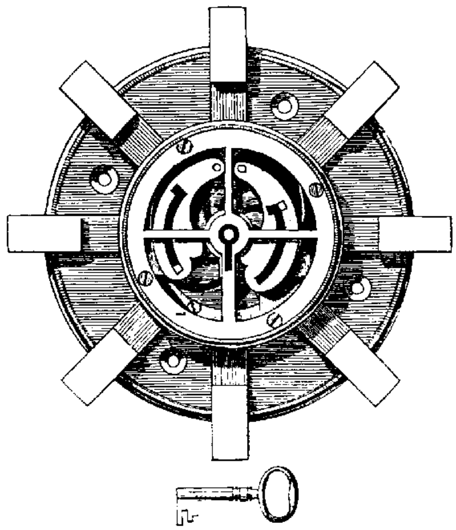

Figure 239. Multiple Lock.

Locks are also made with two or three keys, which require each key to be used successively in a certain order before the bolt can be moved, and such a plan obviates the necessity for having more than one lock.

It is convenient here to notice another kind of multiple lock.

Figure 239 represents a lock of this description, having eight bolts radiating from the centre, all of which are thrown by the small key shown in the cut, by means of eccentric wheels and levers; but in none of these multiple locks (as we have had occasion to observe before) is there any real utility, as greater security is obtained by simpler contrivances.

AUBIN'S CURTAIN-LEVER LOCK, invented about 1846.

This lock was constructed with several discs on a revolving barrel, so that the levers had a circular motion. Each of these circular levers formed a curtain to the keyhole, indeed they made a solid curtain. The barrel and curtain and levers were of the same shape, and all moved together with the key. Curious spaces

were cut out of the levers for the various steps of the key-bit to work against; there were also false notches cut in the circumference, thereby giving a great range of combination. When the true opening or path in the levers was placed in the right position by the key, a loose tongue on which was a stump passed into the levers; and the bolt was shot either out or in as required. The circular levers were kept in their proper position by check or binding springs.

BRIERLEY'S LOCK invented about 1846.

The peculiarity of the construction of this lock consists in fixing a jointed-hasp upon the face of a Bramah lock, on the underside of which is a stud that passes through lock-plate. This lock was adapted to an expanding leather folio or case, containing a number of pockets; these pockets, whether full or empty, are bound with a strap with brass eyelets, which is braced through the hasp, the stud of which passes through and secures it. During the Railway mania these folios were used as "scrip cases," and had an extensive sale. These cases are also made with indexes for letters, invoices, etc., and are extremely useful and convenient.

MORRIS'S DIRECTION PADLOCK, invented about 1846.

This padlock is constructed with a recess in front, in which are placed a dozen or more cards, with a thin piece of transparent horn placed before them. On one side of the recess which contains the cards is a lever secured in its place by the shackle. In using the lock the direction is written on one of the cards, and put into the recess under the piece of horn; the lever or bar is then put back, when it falls into a notch in the back of the shackle-joint; the key is then turned round, and the receptacle, together with the address, is safe.

This contrivance, which was quite a novelty in connection with padlocks, caused them to have an excellent sale, till the inventor reduced the quality of the article, which brought them into disrepute, eventuating their disuetude. We have heard it said that this latter circumstance led to the ruin of the inventor, who had a very large stock of them made, which no one would purchase. A more useful contrivance for the purpose designed we cannot conceive, and hope for the convenience of our commercial brethren some spirited locksmith will resume their manufacture. With a series of printed cards you may change your address as often as desired; and the cards and lock with ordinary

care would last a life-time.

PLANTE'S Lock, invented about 1846.

Plante introduced an excellent improvement into the construction of the common door lock, which he effected by affixing to the pin end of the key that projects through the back of the lock another bit which works outside the lock, and lifts up a spring that is rivetted or screwed on to the back of the lock. On the end of the spring there is a stout peg or stump, which passes through the lock-plate and into the bolt; and before the lock can be unlocked, this spring must be lifted up to release the stud which holds fast the main-bolt

TILDESLEY'S PADLOCK introduced in 1847.

This is a cast padlock, constructed with the patent tumbler of Tildesley and Sanders, invented in 1841 and is known in the market as "Tildesley's Patent Tumbler Padlock." The exterior is similar to Andrews's "American Mail-Bag Lock," from which it appears to have been copied by an individual who had visited America, and who afterwards sold the pirated invention to Mr. James Tildesley, of Willenhall. This lock has always had an extensive sale. The successors of Mr. Tildesley, Messrs. John Harper, jr. and Co., of the Albion Works, Willenhall, manufacture this and similar cast padlocks at remarkably low prices. (See chapter 19.)

NEWELL'S IMPROVEMENTS, Patent dated September 28th, 1848.

These improvements consist in the employment of two metal rings, one of which the inventor calls the key-ring, being accurately fitted and ground into the other. There are two holes bored in these rings exactly of the same size and opposite to each other, leaving a shoulder in the inner or key-ring, against which the key-bolts are pressed by a vulcanized India rubber or other suitable spring; these key-bolts are made of steel, each in two pieces, and are accurately fitted to slide in the holes bored in the rings; the thick part of them being longer than the length between the shoulder of the hole in the key-ring and the outer circumference of the ring, and the thin part projecting into the keyhole, to be acted upon by the key as hereafter described.

The key is formed with two grooves cut on the opposite side of it by a rotary cutter or other means; the grooves are large enough to admit the small ends of the key-bolts to slide along them, and

are formed with irregular or wavy bottoms, which differ from each other, the greatest depths of the grooves being at the end of the key, so that when the key is inserted into the keyhole up to its shoulder, the key-bolts shall be pressed outwards from the centre, and the thick ends of the inner pieces of the keybolts are then made to coincide exactly with the circumference of the key-ring. In this position the outer pieces of the key-bolts can offer no opposition to the key-ring, being turned round by means of the key; but when the key is withdrawn, the spring acting upon the outer pieces presses the inner pieces against the shoulder.

A "feather" on the key fits into the slot of the key-ring to take the strain off the ends of the key-bolts when the key-ring is being turned round, and a pin projecting from the key-ring moves the bolt of the lock. The ring is fixed to the box or case of the lock. When the key-ring has made half a turn, the ends of the key-bolts come exactly opposite to each other; and if the key be withdrawn from its hole, the spring will press the key-bolts against their shoulders in the holes and thrust the outer pieces into the ring, so that the key-ring cannot be turned round except by means of a key which shall press out the key-bolts to the proper distance at the same time.

The number of key-bolts may be increased. If three be used, they must be at equal distances from each other, and a third of a turn of the key-ring will lock or unlock them. If four bolts be used, they may be placed exactly at right angles, and then a quarter of a turn will lock or unlock them; or if two of them be placed opposite to each other, then the other two may be placed opposite to each other at any convenient angle with the other two, and then the key-ring must make half a turn to lock or unlock; if five or six bolts be used, they must be placed at equal distances from each other, and supposing that a pin projecting from the key-ring be used to move the lock-bolt then any number of fifth or sixth parts of a turn (together not exceeding half a turn) will lock or unlock; but if other means be used to move the lock-bolt, then it may be so arranged that any number of turns of the key will lock or unlock. The key-bolts may be arranged in sets one above the other.

YALE'S (America) LOCK invented about 1848.

The YALE lock has two cylinders, one working within the other, and they are held together by a series of pins reaching through the cylinders into the keyhole, which is in the centre. On the back of the inner cylinder is a pin that fits into a slot in the

bolt. and moves it as the cylinder is turned. The pins that hold the cylinders together and prevent the inner one from turning are cut in two at different lengths. The key is so made that by inserting it into the keyhole the pins are moved, so that the joint in the pins meets the joint between the cylinders, and allows the inner one to be turned. But as with the slides of the Bramah lock, should any one of the pins be pushed too far, the cylinder is held quite as firmly as though it had not been touched. Some of these locks have been made with as many as forty pins; and to a person unacquainted with the principles on which locks are picked, they would seem to present an insurmountable barrier.

For the purpose of picking the lock, an instrument is made that will fit between two of the pins, to that is attached a lever and weight, thereby getting a pressure on the cylinder, and causing the pins to bind; then with another instrument the pins are felt, and as they are found to bind, they are pressed in until they are relieved (as they will be when the joint comes to the right place), thereby easily opening the lock.

WINDLE and BLYTH'S LOCK invented about 1848.

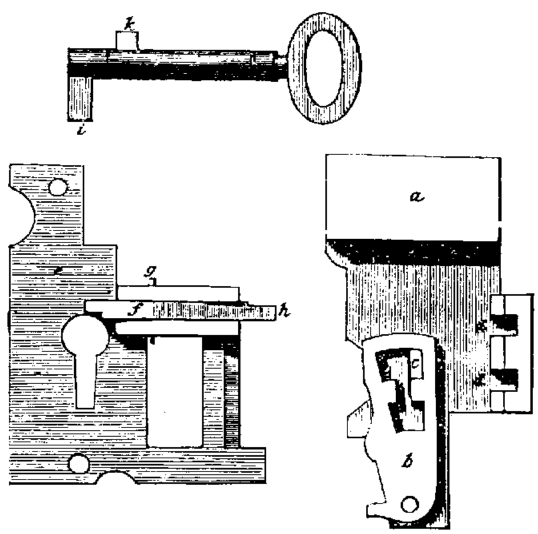

Figure 240. Windle and Blyth's Lock

Windle and Blyth's lever-bolt safety lock is of a peculiar construction. In addition to the usual double-acting levers, it has a set of "lever-bolt guards." Figure 240 represents the principal "limbs" of the lock detached. a is the bolt; b are the levers; c is the stump of the bolt; d d the escape racks for the

lever-bolt f h, which moves upon the axle g, to work in. The key is in two connected pieces, and has two bits, i, k, as shown in the cut; the upper bit, k, having a revolving motion. The bit, or the "rotary barrel-key," by its peculiar pressure, brings the lever-guards to their required position, and so retains them; whilst the key, by the usual rotary motion, acts upon the levers, and at the same time propels or withdraws the bolt at pleasure.

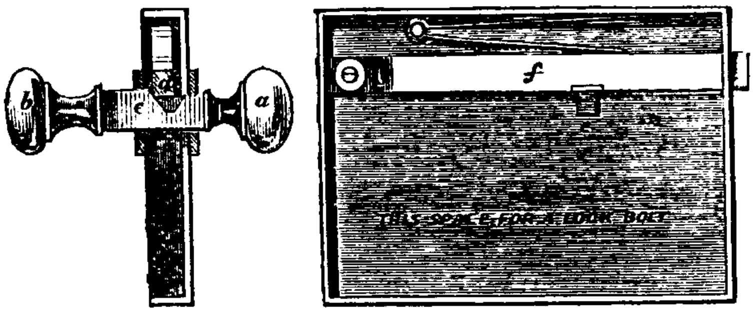

Figure 241. Windle and Blyth's Latch.

They are also the inventors of an improved action to latches, which consists in constructing the spindle with a v-formed channel on one of its squares, which works in a bevelled projecting-piece of the latch, as shown in figure 241. By pushing the knob from you on one side, or pulling it towards you on the other, it lifts the latch-bolt out of the staple or striking-plate, and so opens the door.

WILKES' LOCK, Patent dated May 8th, 1849.

This invention has for its object the use of a shield so arranged that by double locking a lock on the inside the shield will be caused to cover the keyhole, and prevent a key from being introduced from the front.

In the same specification the inventor claims certain improvements in the manufacture of knobs for door-locks and other purposes, and also improvements in the manufacture of lock-spindles.

This latter improvement consists in drilling centre holes on each square of the spindle at such a distance from each other, that by turning the spindle round. it should be certain to fit the various thicknesses of doors. It is secured in its place by a setscrew. This invention merely substitutes the centre-holes for the wormed angles of Duce's spindle.

JONES' LOCK, invented about 1849.

Jones was the inventor of a peculiar kind of stock lock, commonly called "The Drunkard's Lock," from the circumstance of the key always being in the right position to open the lock. The key is something like the figure 8, the end of the bit being as thick as the shank, and drilled out to fit the keyhole. A bolt and a tumbler are fixed on each side of the keyhole, so that let the key be put in which way you will (either up or down) you are sure to meet with the talon of one of the bolts.

If both bolts are required to be shot it is only necessary after locking out the one, to withdraw the key and put it in the reverse way and shoot the other. It is simply two locks in one, which are both worked from one keyhole. This lock will also do for either a right or a left-hand door. It has continued to have a good sale, whether front its peculiar convenience under certain circumstances to certain individuals we do not venture to say.

BRADFORD 'S LOCK, Patent dated July 22, 1850.

The improvements introduced by Mr. Bradford consist in adding to locks spring-bolts or catches, which take into the tumbler, or into the main-bolt of the lock, and are disposed in such positions that the tumbler or bolt cannot be moved with a picker or other such instrument until the spring-bolt or catch has been removed.

The spring is fixed immediately opposite to the lock-pin, which is made hollow, and has fitted into it a small rod or pin, the head of which rests upon the spring. Within the pipe of the key there is fitted another pin of the same size as the pin which is fitted into the lock-pin. The lengths of these pins are so arranged that when the key is put into the lock it causes the first pin to press against the spring, and thereby raise up the fore-end of that spring, which withdraws a third pin, which takes into a hole drilled in the main-bolt.

The withdrawing of the third pin allows the key to push over the bolt. Unless the key used for the lock were provided with arrangements for acting upon the last-named pin, the bolt could not be shifted by it. There is another hole in the bolt which receives this pin when the bolt is in its locked position. This is one of a considerable number of patented locks that have never come into general use.

AUBIN'S BALANCE-DETECTOR LOCK, invented 1850.

This lock is constructed on the principle of the scale-beam. The levers, which are double-acting, are gated at each end with a stump working in each gating. The centre of motion, a, figure 242, is in the middle of the levers; above the centre of motion is a stud or pin, e, fixed to the bottom lever; in each of the other levers is a semi-circular slot through which the pin works. This peculiar construction causes every lever to act as a detector; for if in the least moved out of their true position, the springs d or f pressing against the levers causes them to combine, and so prevents the bolt b from passing. The levers are so delicately poised that very little is required to throw them out of action; the idea was suggested by the action of the scale-beam.

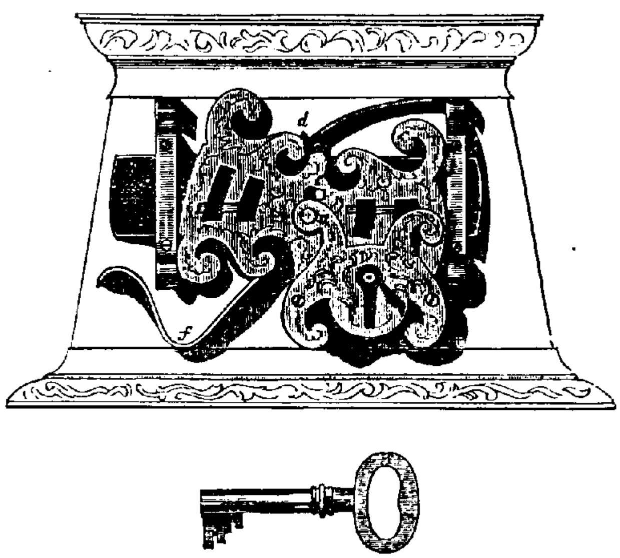

Figure 242. Aubin's Balance-Detector Lock.

AUBIN'S VIBRATING-GUARD LOCK, invented about 1850.

This lock is constructed on Bramah's principle, but with levers or vibrating-guards in the place of sliders. The levers are hung on a split ring, which fits into a groove in the barrel or cylinder b, figure 243. Each lever works in a groove in the barrel or cylinder, and when the key is pressed down it comes in contact with the pointed ends of the levers, and forces them down till the other ends rise to their true position, when the slots in the broad end of the levers are in a line and will pass the

locking-plate, as in Bramah's. If the point or inside end of the lever is pressed down but one-sixteenth of an inch it raises the other end about half-an-inch, which gives it a proportionate range of combination.

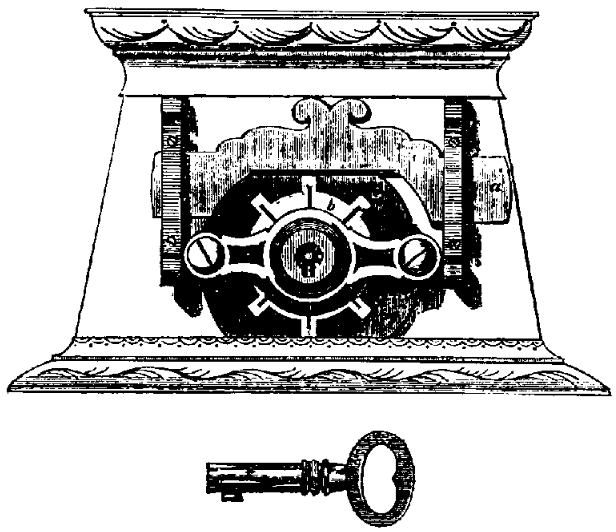

Figure 243. Aubin's Vibrating-Guard Lock.

Another peculiarity is that the key does not touch the bolta, as the latter is moved by an arm of the barrel coming in contact with a stud on the back of the bolt, and consequently the scroll of Bramah's lock is in this lock abandoned.

AUBIN'S COMPOUND-LEVER LOCK, invented 1850.

This is a compound-lever lock, the peculiarity of which consists in one set of levers, with their centre of motion at c, figure 244, acting on another set of levers, their centre of motion being at e. The key enters the lower levers b, and in turning round lifts them, which then come in contact with the necks of the upper levers d, and raises them to their true positions, so that the bolt a can move backwards and forwards. The levers on rising upwards close the keyhole, as in Parsons' change lock. The lower levers, if lifted one-sixteenth of an inch, move the upper levers one inch, thus giving a wide range of combination to the construction of the lock.

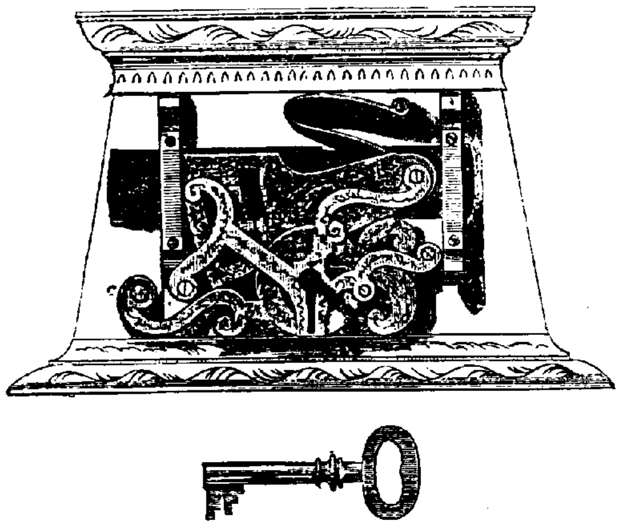

Figure 244. Aubin's Compound-Lever Lock.

This lock was found in practice to be too nicely constructed, as by heating the key in the flame of a gas-light caused sufficient expansion of the metal to prevent its opening the lock. It is undoubtedly a secure lock, but is very expensive to make.

TAYLOR'S LOCK, invented about 1850.

This is a detector lock, and is an improvement on Chubb's inasmuch as the detector acts when the levers are underlifted as well as when overlifted, and it may therefore be called a "double-action detector" lock.

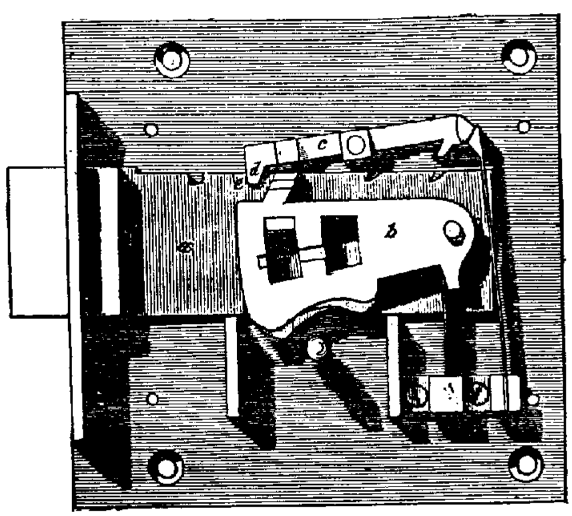

Figure 245. Taylor's Lock.

Figure 245 represents the lock with the cap removed. a the bolt; b the levers; c the detector; d the projecting nib of the detector, which falls into one of the notches in the main-bolt. The action of the lock is as follows:

When the bolt is locked out, as shown in the cut, the projecting nib, d, of the detector is in the second notch of the main-bolt, and before the bolt can be withdrawn or unlocked, this nib must be acted upon at once and equally by the arms of the levers; for if only one of the levers be overlifted, it forces the other end of the detector into the notch at the other end of the main-bolt, and thus prevents the bolt from moving. If the levers are underlifted, the nib of the detector remains in the notch, and again prevents the bolt from moving. This construction allows all the limbs of the lock to be strongly made.

BIGFORD'S LOCK, invented about 1850.

The improvement sought to be effected in this lock consists in the application of a slide or lever action on a part technically called the drill-pin, which, by inserting a false key, presses the end of a detector, thereby making the lock more secure. The advantages of this lock over the lever locks now in use consist in its being so easily detected on the introduction of a false key. The difficulties presenting themselves are:

1st. If the slide is pressed too low it detects the lock.

2nd. If the slide is not low enough the bolt will not pass.

3rd. When the lock is fixed, the proper depth of the work cannot be ascertained (the chief object in picking locks).

4th. The drill-pin and slide can be altered to such a variety of lengths that a lock with four levers is as secure as six levers on any other principle.

5th. It admits of the bolt being left much stronger than hitherto.

The inventor states that "the depth of other lever-detector locks may be easily ascertained without detecting the lock, bu in the improved detector lock this is quite impossible. The levers must be lifted to various heights by the key before the lock can be

opened or shut; and until each lever is at its proper height, the stud (which forms a part of the bolt) cannot pass through the racking in the levers; and if any of the levers are overlifted the lock will be detected, and it cannot then be opened by the proper key in the ordinary way; but notice is thus given, and the detector may be set right by turning the key in a contrary direction, as in locking. No instrument, or any but the proper key can release the detector."

TUCKER'S CLOSED KEYHOLE SEPARATING-KEY LOCK, invented 1851.

This lock, which had for its object the prevention of picking "by pressure," or by "ringing the changes," was an embodiment of that peculiar principle of security in locks, which this inventor was one of the first to apply, and which principle consists (to use his own words) "in the entire closing up of all communication with the moveable security parts of the lock, during the time that the security stump or piece is in contact with or passing through them."

In the present lock this principle was carried out as follows: Viewed externally it presented two keyholes and a knob or handle; both keyholes were perfectly cylindrical, the central or true keyhole being formed by a continuation through the lock-cap of the cylindrical tube of the drum which cantained the slides or security parts. This drum was fixed to the underside of the lock-cap, the sliders working horizontally in it, and radiating towards the centre of the tube. The handle was connected with a horizontal plate or curtain of case-hardened iron, and by its action opened or closed the central keyhole, and drew back or freed the sliders as required.

When the handle was turned so as to raise the curtain and open the keyhole, the keyhole (to the full depth of the lock) presented the appearance of an unbroken tube, affording no communication with the lock's mechanism; but if the handle were reversed, so as to bring the curtain over the keyhole, the sliders could then spring into the tube. Any attempt to raise the curtain (that is, to open the keyhole) would carry the sliders back into the drum, and fix them so that they could not be moved. The key was made in two parts, the lower or bit part being separable from the shank and bow, and requiring to be unscrewed whenever it was used in the lock; the bit of it was circular, its steps or variations being formed by a circle of sinks or recesses of varying depths in it.

The mutual action of the lock and key was as follows: the knob was first turned so as to uncover the central keyhole, the key was then placed into it, and the shank part unscrewed and removed from the lock, leaving the bit behind. The knob was then reversed so as to cover the bit entirely over, closing up the keyhole, and setting the sliders free, so as to allow their points to spring into the sinks in the key. The shank part of the key was then placed into the other keyhole and turned half round, carrying a circle of stumps (to which it gave action) through the gatings of the sliders, and throwing back the bolt.

Were a wrong key used, of course the circle of stumps could not pass the sliders, but would stop or bite against them in such a manner that if any communication with the sliders could then be obtained the lock could be picked; but as during the time such contact of the stumps and the sliders could take place the true keyhole would be hermetically sealed, and as the other keyhole at no time afforded any communication with the interior of the lock, it is clear that no skill could succeed in arranging them, as picking instruments could never reach them.

Picking by skill being thus rendered inoperative, the inventor then provided means to prevent the "changes being rung," which he effected by the use of a detector, so constructed and arranged as to come into operation only after certain of the sliders, which the security stumps must first pass, had been correctly arranged; the detector would then act so as to prevent the keyhole being opened to adjust the remainder.

The operator would in fact defeat himself, as success in his attempts to remove the first obstacles in his way would inevitably prevent any renewal of his experiments. The peculiar arrangement and formation of the key-steps in this lock were such as to throw great difficulty in the way of taking any impression of them. They could only be taken in sections, which would be a prolonged and delicate operation, requiring time, patience, and skill.

The inventor published in his circulars that "The lock placed by him in the Great Exhibition of 1851 was so made and constructed, and would long since have been brought into the market, but for an objection to which, on reflection, it was seen to be liable-that objection being that the key was made in two parts, the lower or bit portion (as it is technically termed) being separable from the shank and bow and requiring to be unscrewed whenever it was used in the lock.

The liability to accidental severance and consequent loss of the key-bit, and the manifest inconvenience attending such a mode of action, were deemed sufficient reasons to prevent its manufacture being proceeded with, although its security against fraudulent or scientific attempts at picking was such as to lead the inventor to invite Mr. Hobbs to operate upon it, conditioning to permit him to take the lock itself in pieces previous to the attempt, and then to allow him thirty days in which to make the experiment."

RESTELL'S LOCKS, invented in 1851.

The construction of Mr. Restell's two locks, which were exhibited at the Great Exhibition of 1851, and which were afterwards patented in December of the same year, we shall describe in the chapter on the modern locks. may, here observe that they were considered of sufficient merit to entitle the inventor to a prize medal.

The lever lock was the only one of a simple construction in the Exhibition that provided against picking by pressure, and was one of the first with the improvement introduced for that especial object.

WOLVERSON'S LOCK, invented about 1851.

This lock was constructed with an improved detector and an entirely new combination of levers, the principle in which seems to be that the levers communicate with three snail-like pans of metal, the effect of the key operating upon which is to throw the detector. The bolt becomes immoveable, and the combination of levers assumes such a position as to render it extremely difficult to open the lock or correct the alteration, from the ordinary position of its several parts, without the introduction of the proper key.

SUMMARY OF THE THIS CHAPTER AND THE GREAT EXHIBITION OF 1851

We have now described all the principal locks invented or known in England previous to the opening of the Great Exhibition of 1851 an exposition, which has been the means of improving the arts and manufactures of this country to an extraordinary degree. We can only form a judgment of inferiority or superiority by comparison, and at the World's Fair we were then shown in what branch of art, and in what articles of manufacture, we were

excelled by the foreign exhibitors. How far the particular manufacture of locks and keys has benefitted by the display and competition and consequent controversy of 1851 must be judged by the merits of the inventions and productions which have been introduced since that period.

Reserving our remarks on this part of our subject for the chapter on the moderns locks, we shall conclude this chapter with a description and illustration of that beautiful and ingenious piece of lock-mechanism designed and made by Mr. Aubin; a table showing the number of the Foreign and British exhibitors of locks at the Great Exhibition; a list of those who obtained prize medals or honourable mention; and the jury's report on locks.

Mr. Aubin's "Lock Trophy" was undoubtedly one of the most ingenious pieces of mechanism in the Exhibition, and we think it deserved a better notice in the Official Illustrated Catalogue than simply "Specimens to illustrate the rise and progress of the art of making Locks, containing forty-four different movements by the most celebrated inventors in the lock trade," more especially as its fabricator was a working locksmith, in humble circumstances. We may remark, too, that the one who appeared to appreciate this valuable specimen most, and who has designated it "The Trophy of Lock Ingenuity," was the American, Mr. Hobbs, who immediately purchased it from its maker.

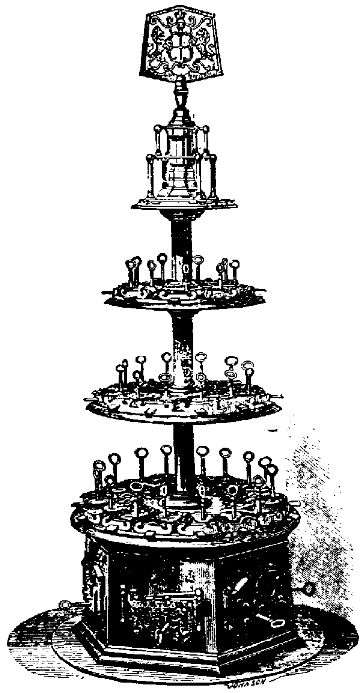

Figure 246. Aubin's Lock Trophy.

This trophy consists of a central pillar or axis about thirty inches in height, which rises from a hexagonal base-piece, the bottom supporting four horizontal circular discs, placed at different elevation from the lowest platform. On each of the vertical faces of the base-plate is constructed a lock, each being worked by its respective key. On each disc or platform there is a number of locks; sixteen on the lowest, twelve on the next above, nine on the third in height; while a Bramah lock surmounts the whole.

All the locks on the three platforms are so arranged that their bolts shoot outwards or radially from the axis or pillar. Each lock has its own proper key inserted in the keyhole; and as the locks lie horizontally, the drill-pin of each lock and the pipe of each key are of course vertical, as shown in the drawing. (Figure 246) There are delicate pieces of mechanism contained within the central axis and the chambers of the platforms, consisting of levers, racks, and pinions; and the Bramah lock is contrived so ingeniously, that its key, by acting upon that lock, acts simultaneously on all this mechanism.

The Bramah barrel, in rotating horizontally under the action of its key, gives a rotory movement to a rod passing vertically

through the centre of the whole apparatus; this rod at the levels of the several platforms acts upon racks and pinions, and these in turn act upon the key-pins rotate, each exactly in the same way as if the lock were being locked or unlocked, and the bolts shoot in or out accordingly.

All the locks are faithful representations of the several patented or other modes of construction to which they severally refer; and each exhibits the works sufficiently open to display the principle on which it is arranged. The works are finished with the utmost care; and the ornamentation and general design of the trophy exhibit a considerable amount of artistic skill highly creditable to its maker. The locks are arranged and numbered according to their similarity of construction, with a view to show how much alike some locks are, and how one inventor has copied the invention of another.

LIST OF LOCKS DESCRIBED WITHIN THIS CHAPTER AND THEIR CHRONOLOGICAL DEVELOPMENT

The following list will ill show where most of these locks have been described in the present chapter :

No. 1, Lock consists of a single bolt, with a binderspring for holding the bolt in any position in which it may be placed until a sufficient force is applied to overcome it; it embodies the simple principle on which thousands of common locks are annually made.
No. 2, Resembles the latter with the addition of a friction-roller. The bolts of either of these two locks can easily be forced back by pressing on the end of the bolt.
No. 3, Is a bolt lock copied from a lock found in an ancient building. It exhibits an improvement on both the former specimens, in so far as the bolt requires, before it can be shot, to be pressed down, in order to release it from a catch at the back end of the bolt. This release cannot be effected without the aid of a key or some other implement applied through the keyhole, and thus the bolt answers the purpose both of bolt and tumbler.
No. 4, Is a single-acting tumbler lock.
No. 5, Is an old English lock, with a double acting tumbler, being a great advance in principle on the single-acting tumbler.
No. 6, Is a modern English single-acting tumbler lock.

No. 7, By Mace, is a double-acting tumbler lock.
No. 8, Somerford's first lock.
No. 9, Has a single-acting tumbler with a pin, copied from a lock on an Indian cabinet.
No. 10, Thompson's lock.
No. 11, Daniell's lock.
No. 12, Walton's lock.
No. 13, Barron's single double-acting turnbler.
No. 14, Bickerton's first lock.
No. 15, Is a peculiar kind of tumbler lock, copied from a Dutch lock.
No. 16, By Duce, Sr.
No. 17, By Sanders, is a lock with four double acting tumblers, and is identical with the next, invented fifty years before.
No. 18, By Cornthwaite.
No. 19, By Richards.
No. 20, Somerford's second lock.
No. 21, Rowntree's lock.
No. 22, Duce's (jr.) firstlock.
No. 23, Parsons' balance-lever lock.
No. 24, Bickerton's second lock.
No. 25, Price's lock.
No. 26, Aubin's first lock.
No. 27, Barron's fly-talon lock.
No. 28, Bird's lock.
No. 29, Duce's (jr.) second lock (patented).
No. 30, Ruxton's lcok.
No. 31, Chubb's lcok 1824.
No. 32, Marr's lock.
No. 33, Tann's lock.
No. 34, Chubb's lock of 1833.
No. 35, Parsons' vertical lock.
No. 36, Young's fly-guard lock.
No. 37, Lawton's lock.
No. 38, Strutt's lock.
No. 39, Scott's lock.
No. 40, Chubb's original detector lock.
No. 41, Parsons' change lock, 1833.
No. 42, Peirce's lock.
No. 43, Ruxton's tell-tale lock.
No. 44, Bramah's lock, showing the improvements introduced by Mr. Rusell and Mr. S. Mordan.

JURY'S REPORT ON LOCKS.

"In the manufacture of locks, Wolverhampton still sustains its ancient reputation. Excellence of Workmanship, lowness of price, and an adequate degree of security characterise the contributions from that place, and prove the advantage of the peculiar division of labour which is adopted in the manufacture. The specimens of locks throughout the exhibition generally evince that the art is in a very advanced state, both here and on the continent, but still it is impossible for the jury to ignore the fact, that the present condition of lock-making is traceable to English ingenuity and invention; and they believe that, on the whole the collection of locks on the British side deserves the place of preeminence.

The lock on the very well-made safe of SOMMERMEIER, of Magdenbourg, (1 Zollv., 802, p. 1094) may be noticed honorably; and the bank lock of Messrs. Day AND NEWELL, of New York, (United States, 298 p. 1453) is remarkable for ingenuity of principle, and for combinations and arrangements which seem to render it impregnable. Locks of this description, if they could be sold at a moderate price, and made available for ordinary purposes, would no doubt be favorably received, and remumerate the inventor.

It is, however, a serious objection to any lock, notwithstanding its ingenuity and security, that the key should be so ponderous and bulky as to require for itself a separate place of deposit and safe keeping. The smallness of the key in proportion to the size and strength of the lock is particularly remarkable in the locks of Messrs. BRAMAH and of Messrs. CHUBB, besides those merits in other respects, which public opinion has so long and so amply recognized.

"On the comparative security afforded by the various locks which have come before the jury, they are not prepared to offer an opinion. They would merely express a doubt whether the circumstance that a lock has been picked under conditions which ordinarily could scarcely ever, if at all, be obtained, can be assumed as a test of its insecurity."

CHAPTER FIFTEEN: The Lock Controversy Previous to and

during the Great Exhibition of 1851

Ne craindra-t-on pas que nous ne donnons en meme temps des legons aux voleurs? Il n'y a pas grande apparence qu'ils viennent les chercher ici, on qu'ils en aient besoin; ils sont plus grands maitres que nous dans L'art d'ouvrir les portes. Apprenons done L'art d'ouvrir les portes femees, afin D'apprendre celui de les fermer D'une manicre qui ne laisse rien ou qui laisse pen a craindre. [1(502)]

PREVIOUS to the Great Exhibition the locks most in general use were Barron's, Bramah's, Chubb's, and Parsons'. These were considered to that period perfectly secure, not only against the ordinary thief, but also against the accomplished pick-lock.

The usual mode adopted by the inventors of locks to test their inviolability was to challenge the trade or other persons to pick them, and in some cases to offer a certain reward to any one who should accomplish the task. We believe Mr. Bramah was the first to do so, who about half a century ago placed in his shop window, in Piccadilly, aboard, to which was appended a padlock (see figures, **251** and **252**), and upon which board was painted the following words:

"The artist who can make an instrument that will pick or open this lock shall receive two hundred guineas the moment it is produced."

In 1817, a very ingenious mechanics attracted by the reward, and fired by the honor of opening this mysterious lock, spent upwards of a week in endeavoring to solve the problem, and eventually gave it up in despair.

In the year 1832, Mr. Chubb challenged a Mr. Thomas Hart, an ingenious locksmith of Wolverhampton, to open *his* lock, and the challenge was accepted.

The following account of this trial, together with Mr. Chubb's letter is copied from the *Wolverhampton Chronicle* of May, 1832:

"During the whole day, notwithstanding the unfavorableness of the weather (the experiment taking place in the open yard of the New Hotel), considerable interest was manifested by a crowd

of factors, manufacturers, and especially locksmiths, who constantly attended till the termination of the trial. The visitors at the inn likewise partook of the curiosity; as we observed Lord Clive, the Hon Mr. Clive, Sir J. Wrottesley, and several other gentlemen very attentive."

"We take no particular interest in any one individual, whether he be Barron, Bramah, Chubb, or any other; but we do feel a deep concern for the quality and reputation of one of the principal and most important articles of our town's manufactures; and we should much regret that, when so large a sacrifice of time, talent, and fortune is made to secure the safety and lives of the public from the midnight deprecator and other thieves, the object should not be attained, or the ingenuity of the mechanist rewarded."

"*ADVERTISMENT*"

"To the Editor of the Wolverhampton Chronicle."

"My letter, which you inserted in last Wednesday's Chronicle would inform your readers of my invitation to Mr. Thomas Hart to meet me at the New Hotel, in this town, on Thursday last, at 4:00 o'clock, to try his skill in attempting to pick my patent locks. At the appointed time I attended with several gentlemen of the town. After waiting an hour Mr. Hart did not appear. He declined to come using the pretense that I had not offered a reward in case he was successful in picking the locks."

"Being desirous of affording him an opportunity of putting his threat into execution, '*that he could pick them very easily,*' I published, early the next morning, a public challenge, and had it posted throughout the town, offering a reward of ten pounds to THOMAS HART, or any other person, who should *fairly pick* one of my improved Patent Detector Locks, that I would affix on a door of the New Hotel on Friday and Saturday, between the hours of ten o'clock and five."

"Accordingly, he came about ten O'clock on Saturday, bringing with him a vice, hammer, files, *blank keys,* and a variety of other articles, and fixed a key-pin in the door, to facilitate his cutting the blanks."

"He then commenced a vigorous and incessant attack on the lock, which he kept up until within ten minutes before five

O'clock, saving when he went to a workshop in the neighborhood, where several workmen were assisting him."

"At that time he gave up the trial, finding he could not possibly succeed. Soon after five O'clock the lock was taken off the door, sealed up by two gentlemen present, and delivered into the hands of Mr. BARTER, the proprietor of the hotel. This so that it might be opened and examined by two principal locksmiths of the town. One being appointed by myself and the other by Mr. Hart. Their job being to ascertain that the lock was made strictly according to my patent. This they did and at the conclusion I received the hearty congratulations of my friends, and repeated cheers from the multitude."

"Such has been the result of this vain boaster, his threats and his affidavits, aided by those of others."

"Since my arrival here I have been made acquainted of the various tricks and nefarious practices resorted to for the purpose of bringing my lock in to disrepute and injuring my reputation. I shall take an early opportunity of exposing the artifices and their authors to the public. Instead of HART attempting to pick the lock, all his efforts were directed to make a key, by the aid of blanks, lamp smoking, & etc., as he found it totally impossible to succeed in fairly picking it, which I required in my advertisement. He was frequently told by the bystanders the means he was trying was most unfair and untenable, but all could not succeed!!"

CHARLES CHUBB

"WOLVERHAMPTON, May 8th, 1832."

"This is to certify that we, the undersigned, having examined the Lock, No. 2,957, U, which was affixed to the door in the yard of the New Hotel, Wolverhampton, and which was attempted to be picked by THOMAS HART, on the fifth day of May, 1832; and we declare it to be strictly one of Mr. Chubb's Improved Patent Detector Locks, without any addition.

"Signed this 7th day of May, 1832.

James Mace, Lock Manufacturer
Bond Street, Wolverhampton.
John Green, Lock Manufacturer,
Stafford Street,
Wolverhampton.

Having discovered that the "Thomas Hart" was still in existence, we thought it only fair, instead of confining ourselves to the

exparte statement of Mr. Chubb, to give also the statement of Mr. Hart, and we do so in his own words.

He says:-

"In 1832, I was then in business on my own account in Wolverhampton, and was in the habit of receiving Chubb's locks to make for a manufacturer of the name of Joseph Richards, who made locks for Mr. Chubb. On one occasion some dissatisfaction was expressed by Mr. Chubb's manager at the locks having been made by me instead of Richards getting them done on his own premised. This led Mr. Chubb's manager to saying that he would not pass my work. To this I replied that he need not be so extremely particular, for that I could construct and make a lock quite as good as Chubb's in a very short time. I afterwards did so, and it was brought out by Mr. Richards. When they came into the market, Mr. Chubb published in the newspapers an advertisement with the name of Mr. Brunnel attached, to the effect that Richards' lock was good for nothing. On Mr. Richards telling me this, I retaliated by saying that I could pick Chubb's lock as easy as I could pick any common tumbler lock. This was afterwards told to Mr. Chubb, and then came the challenge. Now for my account of the said trial."

"At the time I received Mr. Chubb's challenge, I was then working for Mr. Richards as a journeyman. On the Friday the town crier went about the streets crying the challenge, and he did so more particularly before the workshop of Mr. Richards. This provocation proved too much for humanity to bear, and I at once accepted the challenge, and went on the following morning (Saturday) for the purpose of commencing operations. I then and there proposed that the lock to be operated upon should be one of those Mr. Chubb had previously been in the habit of selling as his commercial locks. About two hours were consumed in discussing this point, when it was decided that the lock which was then fixed on an outside door in the New Hotel yard was one of the same kind, but that if on examination it was proved not to be so, then Mr. Chubb would forfeit five pounds to some charitable institution."

"I then commenced operations, and soon found that the lock was not one of his regular commercial locks, for that it contained extra work. The consequence was that having brought with me only a few tin tubes, with a bit of sheet brass soft-soldered to each (with which simple instruments I had frequently opened Chubb’s locks), convinced me that I could not

operate successfully with them, and I was obliged to go to Mr. Richards's shop in the neighborhood to get a key-blank for strength. As this made-up test lock was so constructed that its own key would scarcely move the bolt backwards and forwards. I had previously offered to pick any lock that anyone would go and purchase of Chubb's make from any shop in the town, but this Mr. Chubb would not agree to. He would only consent to the trial of the lock made purposely for the occasion."

"I did not take with me any vice, but a small table-vice was brought without my request or knowledge by some other person, but such vice was not made use of by me. As soon as I inserted the tin tube in the lock, I discovered that it contained a bridge-ward which none other of Chubb's locks ever did contain before. However, not disconcerted but much annoyed, I was compelled to send for a drill and drill-string, for the purpose of drilling the blank-key to pass the bridge-ward, which no other lock required. After I had operated for some time, Mr. Chubb's manager said it was dinner-time, and that if I went to dinner I should be allowed an extra hour at night to make up for it."

"I then went to dinner, and after I returned I got the pick to pass the bridge-ward. I then first threw the detector and smoked the key-bit and applied it to the bellies of the levers, which at that time corresponded to the steps of the key, and were not flush or level-bellied, as made at the present time. I then put in the key the reverse or locking way, which gave me the true gauge for the stepping of the key-bit, which I accomplished by reducing the blank in proportion as the steps were required to be long or short."

"When I found, after stepping the brass key, that it was too weak to shoot the bolt, I went to Mr. Richards' shop, as I have before stated, and got a blank, understanding that I should have the dinner hour allowed me to operate, according as it was promised. While I was away I fitted an iron one to the shape of the brass one, and returned, feeling confident that the iron key would open it. To my surprise found that the lock was taken away, and this was some minutes before five o'clock."

"I had before this time picked eighteen of Chubb's locks, eight of which were sealed separately in papers and sent to me by the late Mr. Mordan, for the purpose of proof, and eight of them I opened at the Deanery, in this town, in the presence of the late Rev. J. Clare, a magistrate; Mr. Wynn, a factor; Mr. Perry, a factor; and Mr. Ebbels, architect."

"The first lock picked by me was ordered specially from Mr. Chubb's factory. It was placed on a block of wood six inches thick."

At this period (1832) Chubb's locks were constructed with but four levers, and these had not flush or level bellies.

It is important to state here that Mr. Hobbs, in operating upon Chubb's lock in 1851, commenced in the same manner as Mr. Hart did in the above trial, *by first throwing the detector.* From the remarks on this subject by the editor of *Herbert's Encyclopedia,* written about the same period, and printed at page 381 of this work, it is evident that this mode of operating on Chubb's locks was at that time understood.

The next account of one of these trials we here copy from a circular published by Mr. Parsons in 1834.

After describing his several other locks, he says, "THE BALANCE-TUMBLER DOOR LOCK has been and will be submitted with confidence to the man of scientific discrimination, solely with its own recommendation; and with the following testimonial in its favor to those who have not the little mechanical knowledge that would enable them to look with a discerning eye at the excellence of its construction in regard to *strength, security, and probable durability.* It consists of a *report* that was made, by the scientific persons whose names are subjoined, *of an unprecedented trial* which a small padlock, containing 26 balance-tumblers, sustained in July and August, 1834. The conclusion of which was witnessed by very many other highly respectable and intelligent persons, who also heard the declarations of the men:-

"On the 21st instant, we witnessed, at the Adelaide Rooms, the total failure of every attempt which could be made by all who applied (three most skillful and long experienced locksmiths) since the advertisement appeared, to make an instrument that would unlock PARSONS' THREE-INCH PADLOCK, for which the patentee in the beginning of last month offered, in several of the London and provincial newspapers, the unprecedented reward of ONE THOUSAND GUINEAS."

"Three candidates appeared, viz. -Thomas Cornell, WHO had been a locksmith about sixteen years and commenced his operations on the 23rd of July. William Hartill, who had been in the trade forty-four years and began on the day following. Joseph Dye, of

thirty-three years' standing, who set to work on the 1st instant. When it is known that the first successful candidate only was to have the prize, it cannot be doubted each spoke truly in saying he had used his utmost energies to succeed, until the termination, on the 21st instant, when they showed that all their efforts were in vain and acknowledged they could not unlock it, although they were in the constant practice of picking all other kinds of locks they met with in general."

"They said that every fair means and opportunity had been allowed them from day to day, and that they were well acquainted with the construction of this kind of lock, but could not even discover how many tumblers the lock contained; but when opened, to show that no deception was practiced, no less than twenty-six tumblers were found to be enclosed within its small case, of the usual size."

"This was never before found practicable by any person but the patentee, who has thus supplied the desideratum, heretofore sought in vain, of locks at moderate price, and of the regular, or even smaller dimensions, perfectly inviolable by any pick-lock or false key. We took the opportunity of examining his other kinds of locks, and feel it right to express our decided approbation; and we have had long and extensive experience in all kinds of the most ingenious patented machinery. His ne plus ultra-THE CHANGE LOCK, in which perpetual changes may be made in the lock and key, is an excellent, yet simple contrivance, to guard against the accidental loss of a key. THE BALANCE-TUMBLER LOCK, of which this trial was made, is the STRONGEST AND MOST SIMPLE TUMBLER LOCK WE HAVE EVER SEEN, AND 1S LIKELY TO BE THE MOST DURABLE."

"CHARLES PAYNE, Adelaide Rooms.
"WILLIAM CARPMAEL, Civil Engineer.
"J.R. JOBBINS, Mechanical Engineer.
"C.F. CHEFFINS, Mechanical Engineer.
"JOHN HENFREY, Engineer.

"London, 23rd August, 1834".

Such were the triumphs gained by three of the principal lock-manufacturers to the year 1851. Bramah's lock when operated upon in 1817, Chubb's in 1832, and Parson's in 1834, all successfully stood the test.

The inviolability of locks appears to have attracted more attention and to have excited much greater interest in America than the subject did here for some years previous to the time of the Great Exhibition. For particulars of the *American Lock Controversy,* we must refer our readers to a very interesting account of it in Mr. Tomlinson's *Rudimentary Treatise on the construction of locks,* which we have had so often to refer to before.

The following passage, however, we extract:-

"Soon after the inventions by Dr. Andrews and Mr. Newell, in 1841 (described in a former chapter), the rivalry between the two locks ran high; each lock being "unpickable" according to the estimate of its inventor. Mr. Newell thought the best mode of showing the superiority of his own lock would be by picking that of his competitor. After several trials, he succeeded in bringing into practical application that system of picking which we may designate the *mechanical,* as contra-distinguished from the *arithmetical.* Mr. Newell not only picked Dr. Andrews' lock, but he wound up the enterprise by picking his own! He was probably the first person who honestly confessed to having picked his own unpickable lock."

This discovery led Mr. Newell to the invention of the triple-action or parautoptic lock which we shall fully describe in the next chapter.

In America the art of lock-picking has been studied and practiced as a science in connection with lock making, while here, and especially amongst the Wolverhampton locksmiths, a distinction has been observed. A kind of opprobium used to be attached to the name of pick-lock;[2(503)] and when one maker discovered that he could pick his neighbor's lock, he usually kept it secret, on the principle that if it became generally known, the whole trade would suffer in consequence. The object was to keep the public in a state of blind security.

Although the very principle by which the American locks were picked was known and promulgated here more than a quarter of a century ago by Mr. Ainger, in the *Encyclopedia Britannica* (see page 306 *ante)*, yet it appears to have either been forgotten, or never to have been applied since that period; therefore, when Mr. Hobbs visited England in 1851, the field was as open for him as any man could have desired, and the success with which his operations were attended proved the truth of all that he had

stated and the certainty of the principle of manipulation. He found that although, as above stated, the discovery of the tentative process of picking locks had been made known, yet that no one in the trade understood it. That every lock that was then being manufactured possessed no real security, because so readily opened by any ingenious operator by applying pressure to the bolt. That all the security affected by the combinations of six levers amounted to nothing.

At the meeting of Civil Engineers in 1850, when Chubb read his paper "On the Construction of Locks and Keys," an interesting discussion ensued, and it is important to note here what was said by the several speakers on the subject of picking locks.

Mr. Farey observed that-

"Chubb's lock was a very improved modification of Barron's, containing six double-acting tumblers combined together, and also possessing the important adjunct of the 'detector,'. In no instance had one of Chubb's locks been opened by picklocks, and, indeed, with a combination of six tumblers, it became exceedingly difficult to make a false key sufficiently accurate to open a lock, because each step of the key required to be just sufficient to lift the tumbler to which that step belonged. If the step was too long the tumbler would be overlifted, and would thereby detain the bolt. If the step was too short it would not lift the tumbler high enough to release the bolt. No indication could be obtained by the trial of a false key in the lock, as to which of the steps was too long or too short."

"The lock would be secured against unlocking by any one or more of the six tumblers, being either overlifted or not lifted high enough; but it could not be ascertained which tumbler detained the bolt, or which step of the false key was incorrect. In such a state of uncertainty all attempts to rectify the inaccuracy of the false key must be directed by mere guess, and alterations were as likely to be made in the steps which were nearly correct, as in those which were wrong."

It was formerly thought that a skilful workman, furnished with impressions taken from the true key, in wax or soap, could make a false key to open any lock and in common locks with the most elaborate wards, but with only one common tumbler. Also, in Bramah's locks, there was much truth in the notion; but for a lock with six double-acting tumblers combined, a false key made ever so carefully, according to impressions, would not be likely

to open the lock for want of exactitude in the lengths of the several steps. If the key could not be made exact from the impressions, there would be no chance of rectifying it by trial in the lock, on account of the total uncertainty as to which part required alteration.

“Chubb's detector being combined with the six double-acting tumblers added very greatly to the security of the lock, for in the course of making trials with a pick-lock or false key, if any one of the tumblers was lifted too high it overset the detector detente which, by a spring action, fastened the bolt so as to secure it from being afterwards withdrawn; and although the bolt should be released from all obstruction by the other tumblers, the fastened tumbler would of itself continue to hold the bolt, as an additional detention, not capable of being removed even by an ordinary application of the true key, which would not go round in the lock after the detector was brought into action, and thus notice was given that a fraudulent attempt had been made to violate the lock."

"To set the detector free, the true key required to be first turned partially round, in a reverse direction, whereby the detector was restored to its quiescent position, and then the true key would operate in the usual manner. It was only by overlifting any one or more of the tumblers that the detector could be brought into action, and the use of the true key could never overlift any tumbler or disturb the detector."

“In making a false key the bit was usually left rather too long, being gradually reduced by trial until the proper length was attained. Though this process might succeed with a common lock, it had no chance with Chubb's lock, which would become detected by one trial with a false key, having even but one step too long, and if a step was too short at first it was not to easy to lengthen it. Hence the maker of a false key was beset with difficulty at every stage of his operations. Without tolerably accurate information respecting the true key it was scarcely possible to find out the combination of the six tumblers, or to avoid bringing the ‘detector’ into action.

Mr. Chubb said, in reply to Captain Moorsom, that if a lock had only one key and it should happen to be lost when the lock was fastened, the door would require to be forced open. Good locks generally had two keys, one of which was deposited in a place of safety. Two hundred and twenty locks might be made with one keyhole and a separate key to each, yet having one master key for

the whole. If a greater number was required it would be necessary to have two keyholes. In the event of the master key being stolen, he knew of no remedy but replacing the locks or altering their combinations.

“It was impossible to take a sufficiently correct impression in wax for the purpose of making a false key, as the locks were manufactured with such delicacy and nicety that the slightest alteration or difference in the key would prevent the lock being opened by it.”

Mr. Varley said that--

“With respect to the number of combinations Of which locks were capable it did appear to him that a certain limit should be assigned to it, in order to prevent any necessity for such close fitting**3(504)** that rust or dust on the key would prevent its opening the lock. A lock was exhibited some time back, the key of which had at first easily opened the lock. When it was warmed the slight expansion caused by the heat prevented the key from acting on the bolts."

"Mr. Hodge said that in America he had repeatedly seen impressions taken of locks having twelve or fourteen tumblers: certainly they were not made by Mr. Chubb, but were such perfect imitations of his locks, having even the detector, that there did appear to be a possibility of picking these locks; in fact, he would undertake to bring a man from New York who would be capable of doing it.”

"Mr. Stephenson, M.P., V.P., imagined that though it might be possible to take a wax impression of a warded lock, such could not be taken from a **tumbler lock(505)**, for there was nothing in a lock of the latter description which could give, by any injection of wax, a knowledge of the length of travel of the different tumblers. He therefore considered Mr. Hodge had raised a problem which did not admit of solution. He would venture to say that it was not possible to pick one of Chubb's locks by the aid of any wax impression."

"Mr. Hodge explained the system he had previously alluded to as having been employed in America for ascertaining the **range of the tumblers(506)**. The process was described to be that the operator, after thoroughly oiling the inside, and inserting two pieces of India rubber to limit the sphere of action, injected from a force-pump, a composition of glue and molasses, in a

heated state, which chilled quickly, and although extremely elastic, had the property of retaining the form and position of the lower side or bellies of the tumblers, and that after being cut out of the lock by a thin-bladed instrument, a key could be made from the impression sufficiently accurate to open the lock. This had repeatedly been done with the best tumbler locks, even on Chubb's principle, although he could not vouch for its having proved successful with any locks made by Mr. Chubb."

He thought that the locks made in New York were generally superior to those made in England, and he attributed it partly to the use of good machinery for the production of the parts of the locks, instead of the primitive tools in use at Wolverhampton and other places, and partly to the small expense of patents in America, inducing the exercise of more ingenuity and invention among practical men. At a late exhibition of the American Institute, fifty or sixty new and ingenious locks, of very superior workmanship, were produced, and he believed that nearly all were invented by practical workmen.

"Mr. Chubb regretted that what had been stated by Mr. Hodge had not happened in London instead of in New York; it must, however, be evident that such a method was totally incapable of application to a lock of Mr. Chubb's own manufacture, though he could not answer for the workmanship, or the security of those made by other persons in imitation of his locks. If a workman did not understand how to make one of his locks, he might leave a similarity between the bellies of the tumblers when at rest and the steps in the bit of the key, but he denied the possibility of this in any of the locks made by him, and in proof of this the locks then exhibited were referred to. There was no reason why the bellies of the tumblers should not be perfectly uniform and in the same plane, and it would be seen from the lock made on that principle that an impression of the inside of such a lock must be utterly useless for any felonious purpose."

"Mr. Stephenson, M.P., V.P., said he had been under the impression that the bellies of the tumblers in Mr. Chubb's lock were *always* flush, or in the same plane, when the lock was in a state of rest, and that the lift of the tumblers was entirely regulated by the notches or steps in the key. Therefore it was evident that unless the impression could be taken from the key, any attempt to make a false key must be futile, and even a facsimile of the interior of the lock would be useless. When the lower side of the tumblers were flush, as in the lock then produced by Mr. Chubb, it did not seem probable that any scheme

could be devised by which an impression of the lock, could afford any assistance for picking the lock."

"Mr. Farey coincided in Mr. Stephenson's opinion of the improbability of the American plan of taking an impression of the bellies of the tumblers being at all effective in aiding to pick a lock really made by Chubb, whatever it might do in the case of bad imitations of that kind of lock."

"Mr. Whitworth said he had much pleasure in bearing testimony to the great value of Mr. Chubb's locks. He used them almost invariably in his establishment, and never found them get out of order. The workmanship in them was of the best kind, and he thought it would be impossible to pick them by the means that had been mentioned, or by any pick-lock keys, as long as the detector was in good order. That was the main feature of the lock and distinguished it from all other tumbler locks."

"Mr. Stephenson, M.P., V.P., said it might be assumed as proved from the discussion, and therefore it was the duty of the institution to express the conviction, that no locks really made by Chubb had ever been picked, either in Great Britain or on the other side of the Atlantic. That they did, in fact, combine that strength, simplicity, easy action, and security, without which the most ingenious locks were utterly useless."

"Notwithstanding the circumstantial description of the ingenious method employed in the United States for taking an impression of the interior of a lock, it had not been proved to have been successful with one of Chubb's locks. Indeed, he must repeat that it was evident it could not be so, unless the lift of the tumblers was identical with the position of the bellies when in a state of rest, which was not the case. If the bellies of the tumblers were flush an impression of them was still more useless."

"The thanks of the institution were most justly due to Mr. Chubb, for bringing before the members so interesting a subject, which he had treated in so able a manner."

"Mr. Chubb said with respect to the locks which had been stated to have been picked, he could assure the members that they had never been issued from his manufactory, although they were very probably marked with his name. Many spurious imitations of the first expired patent, marked 'Chubb's Patent,' had been sold in large quantities, until the makers were stopped by legal

process. It was ruled, both at law and equity, that, although after the expiration of a patent, any person might manufacture the article, he had no right to pirate a peculiar trade mark, or to use a distinctive stamp, which was irrespective of any patent right."

From the statement of Mr. Hart, at page 538, and the remarks of the several speakers who took part in the before-mentioned discussion, it is quite evident that the only method then thought of by which Chubb's locks could be picked was by making a false key. This was to be effected by smoking the key-bit, or otherwise taking such an impression of the "lifts" of the levers as should enable the operator to step a blank which should open the lock.

We have now arrived at the memorable year of 1851, a period which will ever form an epoch in the progress of the arts and of manufactures.

As before intimated, Mr. Hobbs was in full possession of, and perfectly understood, the principle of picking locks by the tentative method. After declaring to a party of scientific men in the Crystal Palace, in 1851, "that all the locks made in this country up to that date admitted of being very easily picked," in order to explain and prove the truth of his assertion, he therewith commenced operating on one of Chubb's six-lever detector locks, which he picked in their presence in a few minutes.

It would appear that the fairness of the above experiment was called in question by certain persons who were not present at the time when it was made, which caused Mr. Hobbs, on the 21st of July, 1851, to write a letter to Messrs. Chubb, "simply announcing that an attempt would be made on the next following day to pick a lock manufactured by them, and which was at that time on the door of a strong room in a house named by Mr. Hobbs. Messrs. Chubb were invited to be present at the operation, but no member of the firm attended." The attempt was successful, and the following certificate relating thereto was published:

> "We, the undersigned, hereby certify that we attended, with the permission of Mr. Bell, of No. 24, Great George Street, Westminster, an invitation sent us by A. C . Hobbs, of the city of New York, to witness an attempt to open a lock throwing three bolts and having six tumblers, affixed to the iron door of a strong room or vault, built for the

depository of valuable papers, and formerly occupied by the agents of the South Eastern Railway Company. That we severally witnessed the operation, which Mr. Hobbs commenced at thirty-five minutes past eleven O'clock, a.m., and opened the lock within twenty-five minutes. Mr. Hobbs having been requested to lock it again with his instruments, accomplished it in the short space of seven minutes, without the slightest injury to the lock or door. We minutely examined the lock and door (having previously had the assurance of Mr. Bell that the keys had never been accessible to Mr. Hobbs, he having permission to examine the keyhole only). We found a plate at the back of the door with the following inscription :-' Chubb's new patent (No. 161,461), St. Paul's Churchyard, London, maker to her Majesty.'

"Mr. Hardley, 26, Great Earl Street.
"William N. Marshall, 42, Charing Cross.
"W. Armstead, 35, Belitha Villas, Barnsby Park.
"G.R. Porter, Putney Heath.
"F.W. Wenham, Effra Vale Lodge, Brixton.

"T. Shanks, Robert Street, Adelphi.
"Colonel W. Clifton, Morley's Hotel.
"Elijah Galloway, 42, Southhampton Buildings.
"Paul R. Hodge, 9, Adam Street, Adelphi.
"Charles Peabody, 1, Norfolk Street, Strand.

This event gave rise to much newspaper controversy, and attempts were made to show that, as this was not a *test* lock prepared expressly for challenge, the picking proved nothing as regards the finest of the manufacturers' locks. Two circumstances, however, have to be noticed. The lock was of sufficient commercial importance to be placed on a door enclosing valuable papers. Also the makers had an opportunity to attend and witness, and comment on the trial, if they so chose."[4]
(507)
The *Times* of September 4 (1851), in publishing the above certificate, made the following remarks:

"The lock controversy continues a subject of great interest at the Crystal Palace, and, indeed, is now become of general importance. We believed before the Exhibition opened that we had the best locks in the world, and among us Bramah and Chubb were reckoned quite as impregnable as Gibralter, more so, indeed, for

the key of the Mediterranean was taken by us, but none among us could penetrate into the locks and shoot the bolts of these makers. The mechanical spirit, however, is never at rest, and if it is lulled into a false state of listlessness in one branch of industry, and in one part of the world, elsewhere it springs up suddenly to admonish and reproach us with our supineness. Our descendants on the other side of the water are every now and then administering to the mother country a wholesome filial lesson upon this very text, and recently they have been "rubbing us up" with a severity which perhaps we merited for sneering at their shortcomings in the Exhibition."

"While we have been relying implicitly upon the artful arrangement of "tumblers" and such like devices, they have been carefully developing their ingenuity in picking and opening locks. A man makes a lock, and he brings it to a mechanics' institute in New York, with a certain sum of money secured by it, which sum becomes the property of the successful operator, who can shoot back the bolt of the new contrivance. Instantly astute heads and clever expert hands are engaged in solving the mechanical riddle thus propounded to them, and so far have these dexterous manipulators carried their art, that their "open sessamee" sweeps springs, tumblers, false notches, letter devices, and everything else before it."

"Mr. Hobbs is by far the most accomplished and successful of these performers, and he has come over to this country at a very opportune moment to teach our makers a very useful lesson. It is well known, however Mr. Chubb may wrestle with the statement, that Mr. Hobbs has succeeded by perfectly fair means in opening his locks as they have hitherto been made. No formal and deliberate trial has taken place between them to establish the fact, but it nevertheless remains undoubted, and the sooner Mr. Chubb improves his patent, so as to set Mr. Hobbs at defiance, the better for his own interests."

Mr. Hobbs has stated that the **principle on which the picking of locks depends(508)** to be, that "whenever the parts of a lock which come in contact with the key are affected by any pressure applied to the bolt, or to that portion of the lock by which the bolt is withdrawn, in such a manner as to indicate the points of resistance to the withdrawal of the bolt, such a lock can be picked." The first step is to produce the requisite pressure.

We may observe that during the present year Mr. Hobbs fully demonstrated to us the easy manner in which the above principle

can be successfully applied. He accomplished this by operating upon an improved patent lock in our presence and picking it in a few minutes.

The following diagrams, with the explanation, are copied from the work edited Mr. Tomlinson, before referred to, which, added to the remarks made at page 306, it is hoped will enable our 'readers to fully comprehend and understand the principle of "picking by pressure"**5(509)** as distinguished from picking by the arithmetical process, or "ringing the changes."

Mr. Tomlinson states that "if the end of the bolt were exposed, this pressure might be applied by some force tending to shoot back the bolt; but as the bolt, whenever it is shot, is buried in the jamb of the door, or otherwise concealed from view, the pressure can in general only be applied through the keyhole. In order, therefore, to apply this pressure, the operator provides himself with an **instrument(510)** capable of reaching the talon of the bolt, which in case of the Chubb lock was a pipekey of the form shown at *a b,* **figure** 247, furnished at the pipe end with that portion of the bit of the key *b c* which moves the bolt, (See **figure** 250, where the step which acts on the bolt is called the terminal step).

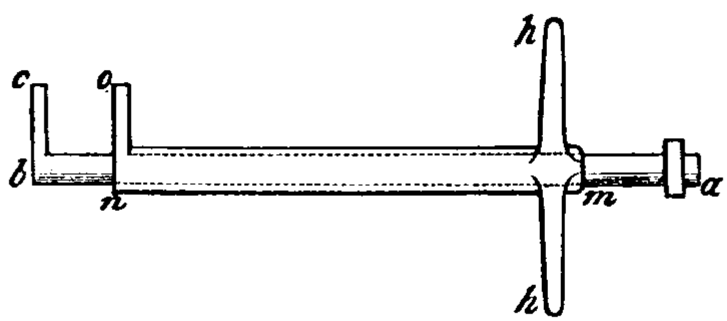

Figure 247.

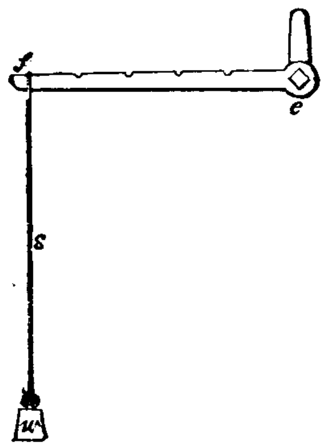
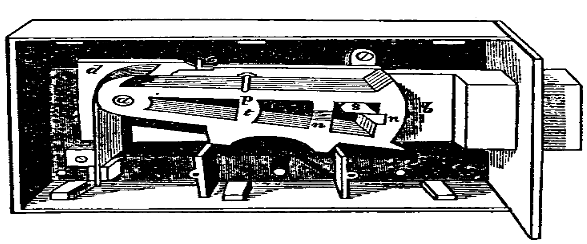
The other end of the pipe-key is made square, as at *a*, for the purpose of receiving the square eye *e* of the lever *e f,* **figure 248**, to the further end of which, *f*, a weight *w* is attached by means of a string *s*. Now it is evident that if this pipe be introduced into the lock as far as it will go, and be turned round as in the act of unlocking, and the lever and weight, be attached to the end *a*, the bit *b c* of the pipe-key will maintain a permanent pressure on the bolt, which, if the weight be sufficient, will throw back the bolt as soon as the tumblers are

raised to the proper height to allow the stump to pass.





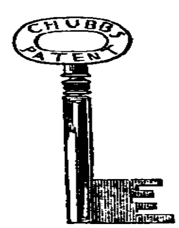


Figure 248.

The next step in the operation is to raise the tumblers to the proper height. For this purpose a second pipe, *m n*, is made to slide upon the first with an easy motion, and by means of the cross handle *h h* can be turned round or slid backwards and forwards on the tube *a b.* This tube *m n* is also furnished with a single projecting bit or step *n* o, corresponding with one of the six steps of the key, **figure 250**, and made of the proper length for entering the keyhole.

Now for the operation of opening, a tumbler lock with this simple apparatus. Referring to **figure 249**, it will be evident that if the pipe *a b, **figure 247***, be passed over the pin of the lock and turned round towards the left, and the weight be attached, there will be a tendency in the bolt to shoot back, which tendency will bring the stump ***s***, **figure 249**, up against the inner angle or shoulder of one or other of the tumblers, whichever happens to project, however slightly.

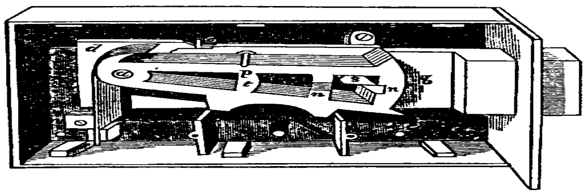

Figure 249. Chubb's Detector Lock of 1851

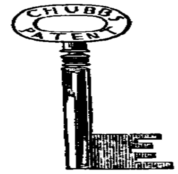

Figure 250. The Key

As Mr. Hobbs expresses it, 'one or more of the tumblers will **bind(511).**' By moving forward the pipe *m n* and turning round the bit *n o* in the lock, it is easy to ascertain, by delicate touch, which of the tumblers it is that binds. It may be found that all are free to move except one or two against which the stump is pressing with the force of the weight *w,* **figure 248.** The bit *n o* is therefore brought gently under the bellies of the tumblers which bind, and they are moved slightly upwards until they cease to bind.

As soon as they are set free another tumbler will bind; that is the bolt will move through a small space, so as to bring the stump into contact with that particular tumbler which now projects; this in its turn is relieved, another tumbler binds and is relieved, and so on until the tumblers are, one by one, raised to the proper height for the stump to pass. When the last binding tumbler is raised to the proper height, the weight *w* being no longer resisted, shoots the bolt back, and the work is done.

Now it must be evident that in this operation the detector apparatus need not come into operation. But if, as has been proposed, a detector spring be added to each tumbler, it may be converted into a friend or a foe according to the use that is made of it. If the tumblers are lifted *too high,* they will be detained or detected in that position, and the operator will have to release them by turning the bit round in the opposite direction before he can begin his work again. The same force, however, which detains the tumblers when they are lifted too high will obviously detain them when they are lifted only just high enough, and thus the detector springs would really be of great assistance to the operator in picking such a tumbler lock.

"The apparatus which we have described for picking the tumbler-lock must be varied to suit the form of the key employed in opening the lock. It is not difficult, in the case of most locks, to ascertain this form through the keyhole, without examining the key itself.[6(512)]

Soon after the picking of Chubb's lock, the friends of Mr. Hobbs were anxious he should try his skill on the Bramah lock referred to at the commencement of this chapter, which, as there stated, had been exhibited in the window of Messrs. Bramah's shop for nearly half a century, and to which was appended a challenge, and a reward of two hundred guineas was offered to any person who should make an instrument that would **pick(513)** or open it.

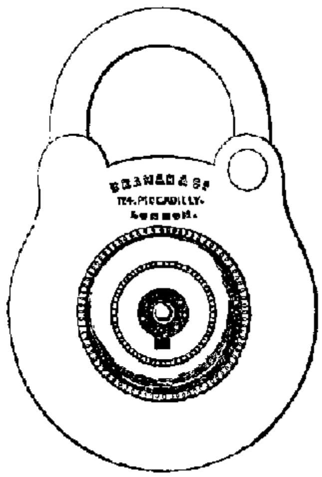

Figure 251. Front exterior view of the Bramah lock

We have received various papers both from Mr. Hobbs and Messrs. Bramah in connection with the picking of this lock, from which we shall endeavor to give an unbiased narrative of the proceedings. We will first describe the lock operated upon.

The lock was a padlock of the following outside measurement; width 4 inches; thickness, 1¼ inch; 2¾ inches over the boss; barrel, length, 2¼ inches; diameter, 1½ inch. **Figures 251** and **252** represent the front exterior and back interior views of the lock which appears to have been made in the year 1801, and had not been opened during thirty-four years, when, doubtless, the false notches introduced by Mr. Russell, in 1817 were made in the sliders and locking plate.

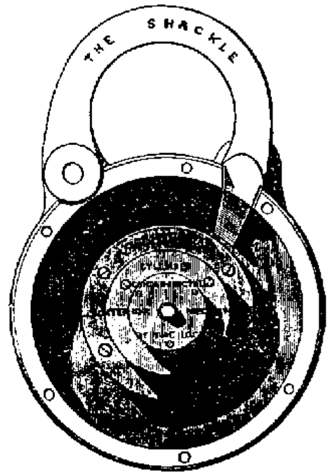

Figure 252. Back interior view of the Bramah Padlock.

It would appear that it was on the 2nd of July that Mr. Hobbs first applied to Messrs. Bramah to be allowed to **examine the lock(514)**, and to take wax impressions of the keyhole. This was complied with, and on the 9th Mr. Hobbs addressed to Messrs. Bramah the following letter;

"Gentlemen - I will call at your place of business, 124,
Piccadilly, on Thursday morning, at ten o'clock and would be
pleased to see you in relation to the offer you make on the
sign in your window for picking your lock.
Yours respectfully,

"A. C. Hobbs"

Mr. Hobbs accordingly called, and on the 19th of July an agreement was drawn up reciting the terms of the challenge upon the painted board, and provided that thirty days should be the term within which the lock was to be opened; that the lock should be secured between two pieces of wood to a wall; and that the key should be in the possession of Messrs. Bramah, who were to retain the right of using it in the lock when Mr. Hobbs was not at work. Messrs. Bramah, in order to remove any grounds of suspicion, and to secure themselves against even the possibility of a charge of interfering with the operations of Mr. Hobbs, relinquished the exercise of this right so far as they were personally concerned, and in an agreement on the 23rd of July stipulated that the key

should be sealed up, and that they would not use it until the operations were brought to a close. They also required that the keyhole should be covered by an iron band, sealed by Mr. Hobbs, when that gentleman was not engaged upon the lock.

A committee was appointed consisting of Mr. G. Rennie, the late Professor Cowper, and Dr. Black, who were to manage all the arrangements, and who were also to act as arbitrators between Mr. Hobbs on the one side, and Messrs. Bramah on the other.

The lock was in due course removed from the shop window to an upper room in Messrs. Bramah's establishment, where Mr. Hobbs commenced operations on the 24th day of July. After having worked at the lock for a week, during which period none of the arbitrators were present, Mr. Hobbs stated that he had made some progress in his labors. Upon which Messrs. Bramah addressed the following letter to Mr. G. Rennie, and similar ones to the other arbitrators:

"124 Piccadilly, July 31st, 1851.

> "Dear Sir - Mr. Hobbs states that he has made certain progress in his operation on the Bramah lock. We cannot say how this is; but as he has been at work one entire week without your inspection, we now beg your attendance before he proceeds further, and hope that you may be able to meet Professor Cowper and Dr. Black at this place tomorrow, at three o'clock.
> "We are, dear Sir, yours truly,
> "Bramah and Co.
> "To George Rennie Esq.

A reply was received from Mr. G. Rennie, who with his two other colleagues was then in Paris, to the effect that he would have liked to have seen the lock from time to time but considered that any inspection upon his part would have had little or no effect. Messrs. Bramah, however, had forbidden Mr. Hobbs proceeding with his labors until the arbitrators had met. On the 8th of August Messrs. Bramah wrote to the arbitrators to the effect that they we're disappointed in not having had an opportunity afforded them of inspecting the lock, and of having the key applied, as they entertained very strong suspicions that the lock was then so far deranged that the key would not have worked if applied.

They stated that though they had voluntarily shut themselves out from the right of using the key themselves, still they never

contemplated either an interference with the duties and discretion of the arbitrators of applying the key to the lock when they thought proper, or of being precluded from having the key used by the arbitrators upon their request. No notice, however, was taken of this application; and upon the 15th of August, at a meeting of the arbitrators, Messrs. Bramah renewed the request to have the key applied, and asked to have a person to attend during the remainder of the operations. Both requests were, however, refused, as the committee saw no reason why the key should be used till the close of the trial, or why any person should witness the further operations, as Mr. Hobbs *had the right, within the thirty days allowed him, to repair any derangement of the lock* which *he might cause during his work.* Accordingly,-

Mr. Hobbs resumed his operations as before on the next morning, the 16th of August. On the 19th of August, Messrs. Bramah addressed a letter to the arbitrators, calling their attention to the fact that the reward of 200 guineas was offered to the artist who could make an instrument that would pick or open the lock, and that he was to be paid the money on its production, and stating that, unless some person were present, it was impossible that anyone could know that the lock had been opened (should it be opened) by the instrument which might be produced.

No reply was received to this communication; and on the 23rd of August, in the presence of two of the arbitrators, Mr. Hobbs *exhibited the lock with the hasp raised, and shot the bolt backwards and forwards.* On the 29th of August, and in the presence of all the arbitrators and Messrs. Bramah, the lock was again shown with the hasp raised, having at the time a piece of *curved iron attached to it,* one end of which was screwed to the woodwork enclosing it, whilst the other, or bent end, was fitted with a *thumb-screw,* the point of which was in and pressing upon a cylindrical rod inserted in the keyhole of the lock.

Mr. Hobbs also produced a small *bent lever of steel,* with which, while the other instrument remained fixed, he turned the barrel of the lock, by which the bolt was turned back and allowed the hasp to enter the socket. Two other instruments, one like *a small stiletto,* and the other like a lady's *crochet needle,* were also produced. *A trunk of other tools* belonging to Mr. Hobbs, and a *powerful reflector* were also in the room. *Messrs. Bramah then applied to have the key used at once, but the arbitrators decided that Mr. Hobbs should have until the following day the*

opportunity of preparing the lock for the admission of the key. On the following day the key was applied, and the padlock was locked and unlocked.

We now insert the report of the arbitrators to whom the Bramah lock controversy was referred:-

> "Whereas for many years past a Padlock has been exhibited in the window of the Messrs. Bramah's shop in Piccadilly, to which was appended a label with these words, 'The artist who can make an instrument that will pick or open this lock will receive 200 guineas the moment it is produced;' and Mr. Hobbs, of America, having obtained permission from the Messrs. Bramah to make a trial of his skill in opening the said lock, Messrs. Bramah and Mr. Hobbs severally agreed that Mr. George Rennie, F.R.S., London, and Professor Cowper, of King's College; London, and Dr. Black, of Kentucky, should be the arbitrators between the said parties; that the trial should be conducted according to the rules laid down by the arbitrators, and the award of 200 guineas decided by them; in fine, that they should see fair play between the parties. On the 23rd of July it was agreed that the lock should be enclosed in a block of wood and screwed to a door, and the screws sealed, the keyhole and hasp only being accessible to Mr. Hobbs, and when he was not operating, the keyhole to be covered with a band of iron and scaled by Mr. Hobbs that no other person should have access to the keyhole.
>
> The key was also sealed up, and not to be used till Mr. Hobbs had finished his operations. If Mr. Hobbs succeeded in picking or opening the lock, the key was to be tried, and if it locked and unlocked the padlock, it should be considered a proff that Mr. Hobbs had not injured the lock, but picked and opened it, and was entitled to the 200 guineas. On the same day, July 23, Messrs. Bramah gave notice to Mr. Hobbs that the lock was ready for his operations. On July 24, Mr. Hobbs commenced his operations, and on August 23, Mr. Hobbs exhibited the lock open to Dr. Black and Professor Cowper. Mr. Rennie being out of town, Dr. Black and Professor Cowper then called in Mr. Edward Bramah and Mr. Bazalgette, and showed them the lock open. They then withdrew, and Mr. Hobbs locked and unlocked the padlock in the presence of Dr. Black and Professor Cowper. Between July 24 and August 23, Mr. Hobbs' operation were for a time suspended, so that the number of days occupied by him were sixteen, and the number

of hours spent by him in the room with the lock was fifty-one.

On Friday, August 29th, Mr. Hobbs again locked and unlocked the padlock in the presence of Mr. George Rennie (and others). On Saturday, August 30, the key was tried, and the padlock was locked and unlocked with the key by Professor Cowper (and others), thus proving that Mr. Hobbs had fairly opened the lock without injuring it. Mr. Hobbs then formally produced the instruments with which he had opened the lock.

"We are, therefore, unanimously of opinion that Messrs. Bramah have given Mr. Hobbs a fair opportunity of trying his skill, and that Mr. Hobbs has fairly picked or opened the lock, and we award that Messrs. Bramah and Co. do pay to Mr. Hobbs the 200 guineas."

"George Rennie, Chairman.
"Edward Cowper,
"J.R. Black.
"Holland Street, Blackfriars, September 2nd, 1851."

On the 2nd of September a letter was addressed by Messrs. Bramah to the arbitrators in the following terms:-

"124, Piccadilly, London, September 2.
To George Rennie, Esq., Chairman of the Bramah Lock Committee.
"Dear Sir, We beg to hand you the minutes of the meetings of the committe, and also the board from our window, on which the challenge is written. The only point to which we wish again to call the attention of the committee is that which has reference to the reward. We fully admit that, under the circumstances detailed in your minutes, Mr. Hobbs did open our lock, and has so far gained for himself much credit for his rare skill and perseverance; but beg to repeat that he has not opened it in such a manner as to entitle him, according to the terms of the challenge, to the reward of 200 guineas."

After reciting the proceedings of the various days, and alluding to the letter of the 19th of August, already refferred to, they state:

"We had at this date learnt enough to know that, whatever

might be the result of Mr. Hobbs' thirty days' operations, the reward could not be claimed; and in order to remove all doubts as to the lock not being opened by an instrument, or anything like an instrument, we wished, if Mr. Hobbs had matured his instrument, that the lock should be readjusted by the use of the key, and that he should proceed to apply them, and open the lock if he could, for which operations nineteen days out of his thirty then remained to him a feat which we did not then believe he could perform. A copy of this letter was sent on the morning it bears date to Mr. Hobbs, to Professor Cowper, and Dr. Black, but we did not receive any reply to it, nor was any meeting of the committee called till after the lock had been opened.

Mr. Hobbs' operations went on after the receipt of this letter, as they had done for the day he commenced them, viz., without inspection and without the key being once applied to the lock. We willingly admit that Mr. Hobbs was at liberty to make any number of instruments, and thus exhaust his ingenuity in finding out one that would open the lock, but we never for a moment agree that he was to be allowed to keep the spring fixed down as long as he pleased during his *thirty days' labor, and affix his apparatus to the woodwork in which the lock was enclosed, while he used at pleasure three separate and distinct instruments to assist him in his operations.* Under such circumstances we hope the committee will see fit to grant us a certificate of the whole facts, of which we take leave to enclose a sketch, mainly taken from the minutes of the committee.

"We are, Sir, your obedient Servants,
"Bramah and Co."

The following appeared in one of the daily newspapers:-

On Saturday last, being the day upon the time allotted to Mr. Hobbs would have finally expired, Messrs. Bramah proceeded to remove the **lock(515)** and take it to pieces, for the purpose of seeing whether the interior had been deranged or injured. We were surprised to find that the lock which has made so much noise in the world *is a padlock of but 4 inches in width, the body of it 1½ inch thick, and its thickness over the boss 2¾ inches. Upon opening the outer case of the lock, the actual barrel enclosing the mechanism was found to be 2¼ inches in length and 1½ inches in diameter.*[***7(516)***]

The small space in which the works were confined, and its snug,

compact appearance, was matter of astonishment to all present. The lock and key were made fifty years since by the present head**8(517)** of the eminent firm of Messrs. Maudslay and Co., Mr Maudslay being at that time a workman in the employ of Mr. Bramah, and the character of the workmanship was highly praised by several of the best hands now in the employ of Messrs. Bramah. The mechanism of the lock consists of two small spiral springs**9(518)** each of four turns of wire of ordinary thickness, and which are required to be pressed down by the key before the lock can be opened. Radiating from the center, and placed in "slits" in the barrels, are eighteen slides, each of which has a number of notches irregularly disposed, and some of which are false.

A circular steel plate is placed horizontally upon the section of the barrel, and until all the notches in the sliders have been so adjusted as to fit into the corresponding notches upon the inner edge of this circular steel plate, the resistance to opening the lock will not be removed. The chances of placing by any means, except by the true key, these notches in their proper places, amount to so enormous a number that their notation can only be expressed by some eighteen or nineteen figures. It is, in point of fact, a permutation lock, similar in its principle to those which have been recently introduced to public notice in France, and upon which Mr. Newell's lock, exhibited by Mr. Hobbs, is made.

It was found on examining the interior of the lock, that portions of the slides presented the appearance of having been considerably bent and straightened again**10(519)** and their surfaces showed marks of their having been filed a great deal; several of them, indeed, being nearly filed through. The slides, it appeared, were made of iron, which could easily be bent to any shape, and it was stated by one of the workmen that, had one of *Messrs. Bramah's present locks* with steel slides been given to Mr. Hobbs, he could never have opened it. The old familiar board, with the same challenge, will, we were informed, occupy its old place in a few days, and one of the locks now manufactured by Messrs. Bramah,**11(520)** with such improvements as have been made in up to the present time, will replace the original one made fifty years since. With the exception of the marks of the filing upon the slides, the lock did not appear to be in any way injured or deranged.**12(521)**

"It may be doubted whether these **experiments(522)** have been productive of any practical result. Mr. Hobbs has increased his fame and reputation as a clever and skilful manipulator, and Messrs. Bramah will pay the 200 pounds. Beyond this, no practical end or purpose whatever has been obtained. Messrs. Bramah are not informed of the mode in which the lock was opened, neither have they been furnished with any instrument that opens the lock, which will enable them to make such alterations as the existence of any such instrument would require, in order to give additional security to their locks. Neither has it answered any scientific purpose, or added one iota to the stock of knowledge previously existing on so important a subject as that of the mechanism of locks, for neither the arbitrators nor Messrs. Bramah saw anything of the process by which the lock was opened. The result of the experiment has simply shown that, *under a combination of the most favorable circumstance, and such as practically could never exist, Mr. Hobbs has opened the lock.*

"In the first place, no person was admitted into the room where the lock was**[13(523)]** besides the operator for sixteen days. The key was never applied to the lock during that time, as would have been the case *almost daily in any lock in ordinary use. The application of the key at any time during the operations of Mr. Hobbs would either have placed all the slides in their correct position, and thus have obliged the operator to begin de novvo after each application,**[14(524)]** or would have shown that the lock had been tampered with, and would in this case act as a "detector" lock.* The padlock, instead of swinging loosely from the staple, as in ordinary cases, was securely fixed. Instead of being fastened in or upon iron, it was secured in wood, which afforded additional facilities for screwing and securing the apparatus.**[15(525)]** He had also the undisturbed use of his trunk of instruments.

"In order to have tested the practical value of the lock, it should have been picked or opened under circumstances more in accordance with those which attend the ordinary employment and uses of locks, or similar to the plan adopted on the trial of Mr. Newell's lock at Boston, an account of which is given in the pamphlet distributed by Mr. Hobbs at the Great Exhibition. From this account it appears that the lock to be operated upon was placed on an iron chest and locked by the committee, in whose hands the key remained during the trial, and was to be used at the discretion of the committee, in unlocking and locking the door, without the knowledge of either of the other parties."

In doing so no alteration of the combination or form of the key was to be made during the process of trial. The operating party had to leave 200 dollars in the hands of the cashier, to be paid to Day and Newell's agent for the lock, in case it should be injured in the process. The lock, in such case, was to be given up to the party making the trial.[16(526)] The time allowed to the operator was one week to operate, and two days to examine the lock previous to commencing operations. Failing these tests, we think that Messrs. Bramah have no reason to regret affording to Mr. Hobbs the fullest opportunity of making trial of his skill. We cannot refrain from expressing our admiration of the great talents and abilities of the late Mr. Joseph Bramah, who, fifty years since, constructed a lock which, after undergoing sixteen days' manipulation of, confessedly, one of the most skilful mechanics of our day, yielded only to the combined action of a number of fixed and moveable instruments made and applied for that purpose.

"We have no wish, in any remarks which we have made, to appear to detract in the least degree from the merit due to the perseverance and the great ability and skill of Mr. Hobbs. The propriety and good feeling shown by him under circumstances of an exceedingly trying character have been exceedingly creditable to him. We are bound, however, to state that, in our opinion, he has done nothing calculated in the least degree to affect the reputation of Messrs. Bramah's lock. His exertions have, on the contrary, greatly confirmed the opinion that, for all practical purposes, it is impregnable."

In an article in the *Morning Chronicle* newspaper of the 10th of September (1851) is the following announcement:

The Messrs. Bramah having ascertained, by opening their lock, that it had not been materially injured by the operations Of Mr. Hobbs, yesterday forwarded to Mr. G. Rennie, one of the arbitrators, a cheque for the 200 guineas awarded by them to Mr. Hobbs. The cheque was accompanied by a letter, of which the following is a copy, and in it Messrs. Bramah state the grounds of their protest against the decision of the arbitrators:[17(527)]

"124, Piccadilly, September 9,1851.

"Dear Sirs:- We beg to acknowledge your letter of yesterday date and will not trouble you to attend here tomorrow, but beg to hand you the 210 pounds awarded by the arbitrators to Mr. Hobbs.

We need scarcely repeat that the decision at which the arbitrators have arrived has surprised us much. We owe it to ourselves and the public to protest against it, and we do so for the following reasons:

"1. Because the arbitrators having been appointed to see 'fair play', and that the lock was fairly operated upon, did not, although repeatedly requested in writing to do so, once inspect**18(528)** or allow any one to witness Mr. Hobbs' operation during the *sixteen days he had the sole custody of the lock and was engaged in the work."*

"2. Because the arbitrators did not once exercise their right of using the key, although repeatedly requested in writing to do so, till after Mr. Hobbs had completed his operations, and then, instead of applying it at once, to prove no damage had been done to the lock, allowed him twenty-four hours to repair any that might have occurred."

"3. Because the lock being opened by means of a fixed apparatus screwed to the woodwork, in which the lock was enclosed for the purpose of the experiment (which it is obvious could not have been applied to an iron door without discovery) and the addition of three or four other instruments, the spirit of the challenge has evidently not been complied with."

"4. Because, from the course adopted, an opportunity of some scientific results has been taken from us, as neither arbitrators nor anyone else saw the whole, or even the most important instruments by which it is said the lock was picked, actually applied in operation, either before or after the lock was presented open to the arbitrators."

"5. Because, during the progress of Mr. Hobbs' operations, and several days before their completion, we called the attention of the arbitrators to what we considered the interpretation of the challenge, begging at the same time that they would apply the key, and appoint someone to be present during the residue of the experiment, feeling that, whatever might be the result in a scientific point of view, the reward could not be awarded. We would add that we think that several points which appear on your minutes should have been mentioned in your award, more especially that Mr. Hobbs, on the 2nd of June, took a wax impression**19(529)** of the lock, and had made, as far as he could, instruments therefrom between that date and the commencement of his operations."

"We are, dear Sir, your obedient Servants.

Bramah and Co.

From "The Bankers' Magazine", October, 1851.

"It will be seen from the notice of the proceedings which we now publish that Mr. Hobbs was engaged on the lock from July 25th to August 23rd, and that the number of days actually employed in working at the lock, independent of those occupied in making his instruments, was sixteen. We think a lock which could stand this test is perfectly safe for all practical purposes. Very few burglars have the scientific knowledge possessed by Mr. Hobbs, and none could have the same opportunities for opening a lock which secured anything of value. Although, therefore, we regret that Mr. Hobbs has been able to show that one of the best locks in the kingdom is not impregnable, we think he has shown at the same time its excellence, and that Bramah's locks may be relied on with perfect confidence as able to defeat any attempt of the most expert thieves and burglars.

"From what we now learn of the construction of Bramah's lock, it seems that, had it been made within the last few years, and with steel slides as now employed, instead of iron slides, Mr. Hobbs would not have been able to open the lock. Without detracting from the ingenuity and industry he displayed, we think that his success was, in some degree, a matter of chance that might never happen again."

"To the Editor of the "Morning Chronicle."
"124, Piccadilly, London, October 10, 1851.

"Sir - This controversy having excited an unusual degree of public attention for some time past, perhaps you will be good enough to allow us to state in your journal that the lock on which Mr. Hobbs operated had not been taken to pieces for many years. It was only on examining it (after the award of the committee) that we discovered the startling fact, that in no less than three particulars it is inferior to those we have made for years past."

"The lock had so long remained in its resting place in

our window, that the proposal of Mr. Hobbs somewhat surprised us; after his appearance, however, no alteration could of course be made without our incurring the risk of being charged with preparing a test lock for the occasion. We were, therefore, bound in honor to let the lock remain as Mr. Hobbs found it when he accepted the challenge. No one inspected his operations during the sixteen days he had the sole custody of the lock and was engaged in the work. We are compelled to adventure another 200 hundred guineas in order that we may see the lock operated upon and opened, if it be possible, and thus gain such information as will enable us to use means that would defy even the acknowledged skill of our American friends."

"We believe the Bramah lock to be impregnable, and we cannot open it ourselves with the knowledge Mr. Hobbs has given us. We have fitted up the same lock with such improvements as we now use, and some trifling change suggested by the recent trial, and restored it with its challenge to our window.[20(530)] We have not done this in a vain boasting spirit on the contrary, we feel it rather hard that from the way in which the former trial was conducted we are driven to adopt this course. Had any one inspected Mr. Hobbs' operations during that trial it would not have been necessary.

We are your obedient Servants,
"Bramah and Co."

From the "The Times" of September 4th, 1851.

"The lock on which Mr. Hobbs operated was made fifty years ago, and had not been opened during thirty-four years. It does not contain the more recent improvements[21(531)] in at least three particulars. It had remained so long in the window of Messrs. Bramah and Co. without an experiment having been attempted, that the proposal of Mr. Hobbs somewhat surprised them. After his appearance, however, no alteration could of course be made without incurring the risk of being charged with preparing a test lock for the occasion. Messrs. Bramah and Co. have fitted up[22(532)] the same lock with such improvements as they now use, which they feel sure will effectually frustrate the attacks of persons as skilful as the celebrated American, and have restored it

> with its challenge to the place of honor it has occupied in their window, 124 Piccadilly, for half a century. Mr. Hobbs has not made a second attempt, although invited to do so.
>
> "The public, while they admire the expertness with which this mechanical feat has been performed, will not attach more importance to it than it deserves, or undervalue the merit of our best locks, because an American operator, highly accomplished in such matters, has succeeded, after an arduous struggle, in opening them. The facilities given to him were such as no thief could ever possess, even if he had the necessary ability. It is quite clear that the operation has not been one of ordinary picking."

The following is a **description(533)**, so far as can be given in words, of the mode in which Mr. Hobbs operated on the Bramah lock: "The first point to be attained was to free the sliders from the pressure of the spiral spring. The spring was very powerful, pressing with a force of between thirty and forty pounds. Until this was counteracted, the sliders could not be readily moved in their grooves. A thin steel rod, drilled at one end, and having two long projecting teeth, was introduced into the keyhole and pressed against the circular disc (see *b*, ***figure 122***), between the heads of the sliders; the disc and spring, were pressed as far as they would go. In order to retain them in this position, a curved stanchion was screwed into the side of the boards surrounding the lock, and the end brought to press upon the steel rod, a thumbscrew passing through the drilled portion of the instrument and keeping it in its place."

"The sliders being thus freed from the action of the spring, operations commenced for ascertaining their proper relative positions. A plain steel needle, with a moderately fine point, was used for pushing in the sliders; while another, with a small hook at the end, something like a crochet-needle, was used for drawing them back when pushed too far. By gently feeling among the edge of the slider the notch was found and adjusted, and its exact position was then accurately measured by means of a thin and narrow plate of brass, the measurements being recorded on the brass for future reference. The operator was thus enabled by this record to commence each morning's work at the point where he left off on the previous day."

"The lock having eighteen sliders, the process of finding the exact position of the notch in each was necessarily slow. Mr. Hobbs employed a small bent instrument to perform the part of

the small lever or bit key. With this he kept constantly pressing on the cylinder which moved the bolt. He thus knew that if ever he got the slide-notches into the right place, the cylinder would rotate and the lock open. He could feel the varying resistance to which the sliders were subjected by this tendency of the cylinder to rotate. He adjusted them one by one until the notch came opposite the steel plate. The false notches added, of course, much to his difficulty; for when he had partially rotated the cylinder by means of the false notches, he had to begin again to find out the true ones."

Mr. Hobbs, in answer to our inquiries relative to several statements in the foregoing extracts, has furnished us with the following particulars, in addition to the footnotes on previous pages: -

"TIME OCCUPIED ON THE BRAMAH LOCK."

"July 23.-In the room . .	0 hours	12 minutes	
"July 25.- " . .	0 "	35 "	
"July 27.- " . .	3 "	25 "	
"July 29.- " . .	7 "	15 "	
"July 30.- " . .	7 "	15 "	
	18 hours	42 minutes;	

Being the whole time from commencing until the cylinder was turned round. After turning the cylinder, I was in the room putting up my tools, etc., 45 minutes. When the cylinder *began* to turn I found that my instrument was not strong enough, and I then left the room and did not return till the next day, when upon calling at Messrs. Bramah's I was refused admission into the room and was excluded until the return of the arbitrators. At which time I was permitted to commence my second operation. I began by first getting back the cylinder to its original position. I was in the room on:

"August 19th	7 hours	15 minutes
"August 20th	7 "	20 "
"August 21st	1 "	10 "
"August 22nd	7 "	0 "
	22 hours	45 minutes

I then readjusted the cylinder, and on August 23rd I was in the room 1 hour and 55 minutes, and picked the lock. The time occupied in the actual operation of picking the lock was 20 hours 37 minutes. The time spent in readjusting the cylinder, an accident caused by the unusual strength of the spring, was 22 hours 45 minutes. I afterwards picked the lock three times within an hour, in the presence of the arbitrators.

We shall conclude this chapter with the following extract from *Fraser's Magazine* for November, 1852, relative to the Jury's Report on Locks:

> "This jury seems to have consisted of the only persons in England who did not hear of the famous 'lock controversy' of last year. One can hardly imagine that, if they had heard of a matter of so much consequence to the subject they were appointed to investigate, they would have altogether abstained from saying anything about it. They may be excused for not knowing, because very few did know, fortunately for our safes and strong boxes, that the mode of picking Bramah's and Chubb's locks, by which the transatlantic Hobbs gained so much glory, was suggested and explained in the *Encyclopedia Britannica nearly twenty years ago."*
>
> *"But it does seem very strange that they, or at least their reporter, should not have known, long before the report finally left his hands, that Hobbs had picked both of those locks, and taught every lock-picker in England how to do it, if he possesses the requisite tools and fingers. Of course, however, the reporter did not know it, as nobody could read any newspaper last autumn without knowing it. And this jury did exercise their judgment to the extent of declaring that Hobbs' own lock (under the name of Day and Newell) 'seems to be impregnable.' Notwithstanding all which, they express their inability to "offer any opinion on the comparative security afforded by the various locks that have come before them."*
>
> *"The only discrimination which they venture to make is that the keys of Bramah's and Chubb's locks are of convenient size, while Hobbs' is ponderous and bulky, and his lock complicated; and they might have added (without any very painful amount of investigation) enormously expensive, in consequence of its complication, and probably also more*

likely, on the same account, to get out of order and stick fast, and so become rather inconveniently impregnable - on the money-door of a bank, for instance - than the other two locks, especially Bramah's."

CHAPTER SIXTEEN: On the Modern Lock

BELLFORD'S LOCK:, Patent dated April 25, 1855.
HENDERSON'S LOCK, Patent dated May 11th, 1855
TUCKER'S HOLDFAST LOCK, Patent dated May 21st, 1855.
NETTLEFOLD S LOCK, Patent dated June 9th, 1855.
SCULLY and HEYWOOD'S LOCK, Patent dated July 15th, 1855.
BUTLER'S DIAL LOCK, Patent dated August 13th, 1855.
NEWTON'S LOCK, Patent dated November 14th, 1855.
FENTON'S LOCK, Patent dated January 21st, 1856.
TUCKER S SAFETY LOCK, Patent dated June 13th, 1856.

As was to be expected from the interest manifested in, and the excitement caused by, the *Lock Controversy* during the Great Exhibition of 1851, the subject of locks and keys has since that period assumed an importance unknown before in the connection with the arts and manufactures of this country.

Instead of the principles upon which locks in general are constructed being understood only by those immediately connected with their production, the whole subject in all its details has been studied by a considerable portion of the intellectual and intelligent classes, so much so that it is beginning to be ranked with the sister arts in importance, and is attracting the attention and drawing forth the abilities of a class of inventors which, if but little of *real* merit has been the result of their conceptions since the year 1815.

The specifications of the numerous patents taken out since that period prove that the faults in the old locks are fully understood. The determination to remedy them is evidenced by the numerous contrivances, more or less simple, which have been introduced for that purpose. The number has doubtless been augmented by the beneficial alteration in the patent laws.

We are certainly indebted to Mr. Hobbs for having initiated this spirit of emulation in improving these useful machines, as it was he who so easily proved that all our best locks constructed to the year 1851 were altogether defective in one important particular. ***That the picking by pressure had never been provided against.*** We are convinced that Mr. Hobbs could have picked any other lock invented to 1851 as easily as he opened Chubb’s.

As before stated, although this liability of locks to be picked had been not only conceived, but explained and published, yet but few, if any, of the locksmiths understood it, as the only contrivances to prevent it consisted in the false notches in Bramah’s sliders, introduce by Mr. Russell in 1817, and the false

notches in the levers and stump of Strutt's lock, patented in 1819.

From the extracts in the last chapter, it will be apparent that the only means then thought of by which the improved locks invented to the year 1851 could be picked was by making a false key. In the following lists of patented and other locks, which we shall describe as fully as their merits deserve, it will be seen that in most of these inventions the principal object has been to render the locks perfectly secure against the tentative process of manipulation.

The methods adopted are various, and in the majority of cases it has been sought to accomplish it by the most complex movements. The prevailing contrivance will be found to be the adoption of ***false* notches** in the gatings of the levers and the notches on the *ends* of the levers, as in Strutt's lock.

We shall notice these and other peculiarities of construction as we proceed, simply remarking here that nine-tenths of the patented locks are the inventions of those unconnected with their manufacture, and, with few exceptions, the movements are the very reverse of what we have before laid down as the object which all inventors should have in view and endeavor to attain: simplicity of construction.

The diagrams annexed to some of the specifications in the following list of patents are more like the drawings of a steam-engine than the illustrations of the simple piece of mechanism a lock should be. The descriptions of many of them are so long in consequence, that we have been compelled to abandon our intention of noticing them all. Had we have done so, it would have been more from their curiousness which might have acted as a caution to others not to follow in the same path of complicated constructions, which could never be made useful, than from any intrinsic merit they possess in themselves.

Inventors should always bear in mind that any article to be generally adopted must not only be useful, but of such a construction that the mechanics or artificers in the trade may readily make it. We have no hesitation in saying that with the majority of the following locks, however meritorious the improvements might be considered, and however desirable it may be to adopt them, the patentees would be utterly unable to get such locks made in quantity.

Any locksmith will easily go from one lock to another more simple in its details, but complicate the movement ever so little and he is all abroad. We have stated before that complication is too often the idea prevalent in the minds of most inventors, and that this is so in respect to locks is evidenced by the construction of most of the locks invented previous to and since the opening of the Great Exhibition of 1851.

PATENTS GRANTED FOR LOCKS AND LATCHES SINCE THE CLOSING OF THE GREAT EXHIBITION OF 1851, TO JULY, 1856, INCLUSIVE

NO. OF PATENT	YEAR	DATE	NAME OF PATENTEE
13,802	1851	NOV. 4	DISMORE, GEORGE
13,806	1851	NOV. 6	PARNELL, MICHAEL LEOPOLD
13,807	1851	NOV.13	SINCLAIR, WILLIAM
13,852	1851	DEC. 8	RESTELL, THOMAS
13,985	1852	FEB.23	HOBBS, ALFRED CHARLES

The above patents were granted under the old law.

THE FOLLOWING PATENTS HAVE BEEN GRANTED UNDER THE PATENT LAW AMENDMENT ACT, WHICH CAME INTO OPERATION IN 1852.

The following is a list of locks invented since the closing of the Great Exhibition, but which have not been patented. All of these will be described in the following pages:

TITTLEY'S LOCK, Invented in 1851
LEAS LOCK, invented 1851
DISMORE LOCK, patented 1851
PARNELL'S DEFIANCE LOCK, patented dated Nov. 6th, 1851.
SINCLAIR'S LOCK, patent dated November 13, 1851.
RESTELL'S LOCK, patent dated December 8, 1851.
HOBBS' PROTECTED LOCK, patent dated February 23, 1852.
TUCKERS CLOSED-KEYHOLE DETECTOR LOCK, patent dated October 1st, 1852.
ROSE'S Lock, Patent dated October 21st, 1852.
CHUBB'S LOCKS, containing the improvements patented by John Chubb, November 1st, 1852.
WHISHAW'S MAGNETIC Lock Patent dated January 29, 1853.
JENNINGS LOCK, Patent dated January 29th, 1853.
SIMSON'S DUPLEX BANK LOCK, Patent dated May 2, 1853.
PARNELL'S SECOND LOCK, Patent dated September 9th, 1853.
TUCKER'S SAFE GUARD LOCK, Patent dated Nov. 21st, 1853.
GIBBONS' DETENT LOCK, Patent dated December 22nd, 1853.
SAXBY'S LOCK, invented 1853.
DENISON'S LOCK, Invented 1853.
GIBBONS' DOUBLE-DETECTOR LOCK, Patent dated 1853.
DANIEL'S IMPROVEMENTS, Patent dated February 1st, 1854.
TANN'S LOCK, Patent dated March 2nd 1854.
TANN'S NEW PATENT BANK LOCK.
YOUNG'S LOCK, Patent dated June 12th, 1804.
WOLVERSON'S LOCK, Patent dated July 11th, 1854.
MILES' LOCK, Patent dated August 4th, 1854
LEWIS'S LOCK, Patent dated September 2nd, 1854.
NEWTON'S LOCK, invented by L. M. Eiler, of Copenhagen, Patent dated October 3rd, 1854.
WENHAMS LETTER LOCK, invented 1854
WOLVERSON s LOCK invented about 1854.
BELLFORD'S LOCK:, Patent dated April 25, 1855.
HENDERSON'S LOCK, Patent dated May 11th, 1855
TUCKER'S HOLDFAST LOCK, Patent dated May 21st, 1855.
NETTLEFOLD S LOCK, Patent dated June 9th, 1855.

TITTLEY'S LOCK, INVENTED IN 1851.

The peculiarity of the construction of this lock consists in the introduction of a "segmental slidecap". In other respects it is an ordinary lever lock. "Its leading principle is that, immediately on the introduction of the genuine key, or any other instrument bearing upon any one of the levers or springs, for the purpose of opening the lock, a steel shield presents itself at and covers the keyhole, effectively preventing the introduction of any second instrument, or any reflector for the purpose of examining the interior of the lock."

The introduction of this "segmental slide-cap" led to the adoption of the barrel and curtain combined, by Mr. Chubb and other makers. Chubb's and other makers locks were frequently sent to Mr. Taylor, lock manufacturer, Wolverhampton, in whose employ was Mr. Tittley, to have the former invention applied to them.

LEAS' LOCK, invented 1851.

The top levers in this lock work on a pin fixed into the bottom lever, which latter with the others are placed upon another pin riveted to the main plate of the lock, as in other locks. The security consists in so gating the levers to the stump of the bolt, as that when pressure is applied to the bolt, one of the levers ***recedes*** and throws the detector, which is released in the usual way. The curtain in this lock is identical with Higginson's, described earlier in this text.

DISMORE'S LOCK, patent dated November 4, 1851.

The improvements claimed by Mr. Dismore consist, first, in forming a tube with an enlargement or boss, which rotates within a projecting cylinder, and it has fixed on it a spring, which at its bent pointed end, springs into a notch, and retains the parts in a correct position for the introduction of the key. In addition to these parts, there is a fixed plate that may be made

of steel, through which there are two openings; the one for the key to pass into the lock, and the other for it to pass out at. There is a stop to the key to prevent its passing beyond the correct position.

Secondly, in constructing a striker-plate suitable for the above arrangement, the bolt of the lock is shot by means of a spring, when permitted to do so by the catch being out of the way, and it will at all times when shutting the doors be lifted by means of an incline in the striker-plate. On the other hand, the bolt will be held back by the catch, and when the door to such a lock is fastened, is opened.

The lock is so arranged that it may be opened on one side by a key suitably formed according to the tumblers or wards, or such like parts. A lock constructed in this manner may be opened on the other side by a handle on the spindle, which by its bit acts on a lever, the face of which comes against the tail ends of the tumblers or levers. These are properly formed to be acted upon by the face of the lever, so as to move them into position to allow the bolt to come back. It will do so by means of the bit in a pin pressing against the lever, which lever acts as a fulcrum, and carries the pin which draws back the bolt.

Thirdly, in so making the key that **the bit(534)** can be separated from the stem. The patentee states in his specification that "the convenience offered by thus having the 'bit' of the key separate from the stem will readily be understood, particularly in regard to large keys, as it admits of the 'bit' end being more conveniently carried about the person, whilst the stem may be kept in any convenient place, the possession of the stem only of the key by any person giving no means of opening the lock.

PARNELL'S DEFIANCE LOCK, patented dated Nov. 6th, 1851.

This is a lever lock, with the addition of a cylinder or curtain. The key has an expanding bit. The patentee states that "the security of the lock consists in the number of the levers, and in their slots being cut and placed in an uncertain and irregular order, requiring a corresponding irregularity in the bits of the key to raise the slots or gatings to the proper height for the stump to pass. If a false instrument be used, and but one of the levers be raised either too high, or not high enough, the stump could not get out of the chamber, nor the lock by any possibility be opened."

"Viewing the lock from its exterior, it presents nothing remarkable. But upon removing the cap plate, it will be seen that all possible access to the mechanism with false or surreptitious keys is effectively prevented by a solid cylinder of hardened brass, with protecting wards extending the whole depth of the lock, and having the center of the aperture for the key, which fits to a mathematical nicety so exact as to preclude the possibility of any second instrument being used to open it."

"This protecting cylinder must revolve with the key to get to the works and the moment it passes from the keyhole, in going round to lock or unlock, the solid portion moves into its place, and so completely closes that aperture that the point of a pin, or a fine steel pen, has failed to be inserted between it and the outer plate or cap, to say nothing of the utter hopelessness of perforating the metal."

Figure 253 represents the action of the lock. **A** is the curtain, stopped by the upright bolt **F**. **B** is the bolt; **D** the levers; **E** the double-action latch.

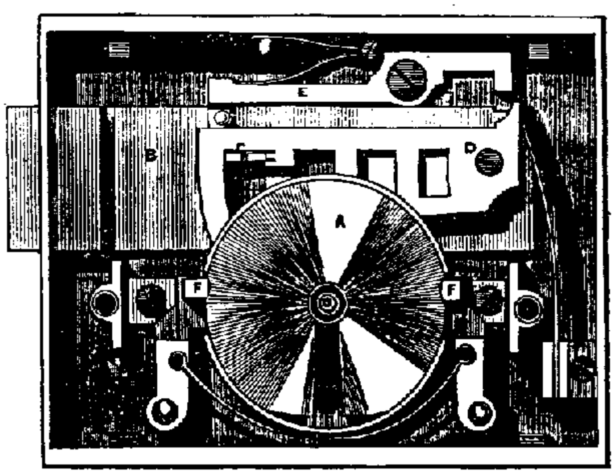

Figure 253. Parnell's Defiance Lock

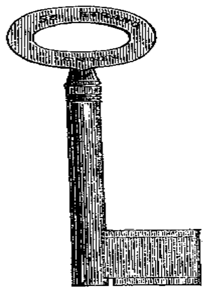
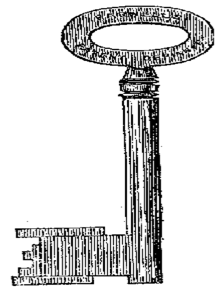
Supposing the key inserted in the lock in its locked position, as shown in the cut, for the purpose of unlocking it; the key, after passing about one-third way round, meets with the forcible resistance of the upright spring-bolt or defector **F**. which is made of steel, and acts on the revolving-cylinder or curtain. The key, after passing this obstruction, arrives at the levers. In the bolt-stud, which works in the slot of the levers, there is a small deep serrated notch on one side, corresponding to similar notches on each of the levers; if, therefore, pressure be applied

to force the bolt, these notches would lock into each other.

There is also a double-action latch placed over and shooting into the main-bolt, which, when the lock is forced, bears all the strain, thus effectually rendering all attempts on the lock futile and vain. The stump shooting into the levers locks them down, which is an additional preventive against any attempt on the levers succeeding.



The patentee further states that "the key of the defiance lock is entirely original in its form, and, when not in the lock, appears like a highly-polished blank or key before the wards or bits are cut in it."



In this form it enters the lock, and fits on the edge of an eccentric steel plate at the bottom of the pin. The moment the key begins to move, the bits corresponding to the levers are gradually forced out by its action round the eccentric plate, so that when it has made a quarter of a revolution it has become slightly elongated, which enables it to pass the first impediment, the sentinel-bolt, and by the time it has arrived at the levers it has expanded about one third its whole length; then it lifts the double action latch, adjusts the levers, and shoots the bolt. In bringing it out of the lock again, a contrivance forces it back to its original shape; presenting nothing, to all appearance, when out of the lock, but a blank key.

The advantage of this sliding-bit in the key is of great importance. No attempt can be made to produce a duplicate from merely seeing it, and if an impression of the key be taken, the skeleton key made from the impression will, to be sure, get into the keyhole, but it will be arrested immediately by the sentinel-bolt **F**. and turned back; or, should the sentinel sleep at his post (steel bolts, worked by steel springs, do not sleep) nothing would be gained, for the key would but revolve on its centre pin, without having the slightest effect on the levers. On the other hand, were a key made capable of acting on the levers, it could not get in at the keyhole; the key that can get in cannot work, the key that can work cannot get in. Figures 254 and 255 show the keys in and out of the lock.

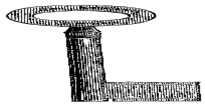


Figure 254. The Key as it appears when out of the lock.

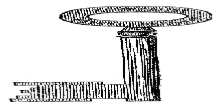

Figure 255. The Key when in the Lock acting on the Bolt and Levers.

There is but little new in the construction of this lock, and the expanding key-bit was invented by Mr. Machin in 1827, as described elsewhere in this text. When well made, this lock affords an average amount of security, but the construction of the key permits but of a very limited number of combinations. (See the chapter on K*eys and differs*)

SINCLAIR'S LOCK, patent dated November 13, 1851.

The improvements introduced by Mr. Sinclair have relation to tumbler locks, and consist of the following innovations.

First: In combining the action of two or more of the tumblers of a lock in such manner that they shall be individually incapable of being brought to the position requisite for the admission of the locking-ring, pin, or plate, or in such manner that the movement of any one of the tumblers shall produce upon the others a locking effect, which would prevent their being moved.

Secondly: In combining with wards or escutcheons a revolving-shield or plate, which will have the effect of preventing the introduction, or increasing the difficulty of, introducing picking instruments.

Thirdly: In the employment of a serpentine of zigzag gate or way for the introduction of the locking-pin, and in the application of a compound motion to the tumblers, the effect of which is, that by once turning round the key a double or triple locking may be produced.

Fourthly: In the adaptation of a dial or indicator to tumbler locks, whereby the changes of the tumbler may be varied according to the permutations of a moveable bit-key, or whereby, in combination with other apparatus, the positions of the parts of the lock may be so arranged after the act of locking, as to prevent the possibility of the lock being opened, even with the legitimate key, without the knowledge of the secret arrangement.

Fifthly: In dispensing with the shackle and eyebolt of padlocks, or either of them, and in causing the bolt of the lock

to be held, and the locking effected by means of pins or projections on, or holes or recesses formed in a plate of metal to which the lock is attached.

RESTELL'S LOCK, patent dated December 8, 1851.

The principal feature in the construction of this lock consists in constructing the keyhole in such a manner as that not more than one instrument can be introduced into the lock at one time for the purpose of picking it. Further, that if any instrument other than the proper key be introduced and turned partly round, it will meet with an obstruction, as usual in all combination locks, but cannot be withdrawn therefrom until all the internal parts have been brought back into their original position.

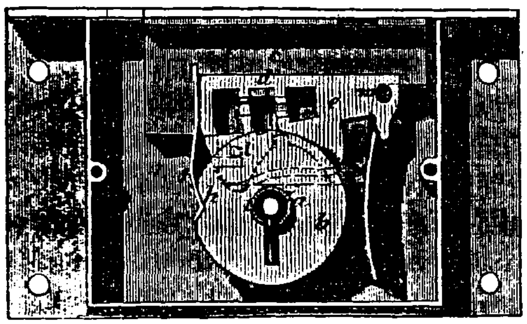

Figure 256. Restells Lock.

This objects effect is one of the *barrel and curtain combined,* as when the key or other instrument is introduced and turned round in the keyhole, the curtain or shield ***b*** (figure 256) is carried round inside the lock, and covering up the hole, thereby prevents the introduction of a second instrument.

So far there is nothing new in the invention. In order to prevent the key from being turned in the wrong direction, a projecting stud or tooth, ***f***, (figure 257) is formed on, or attached to the periphery of the curtain. When the barrel and curtain is turned around either way, this tooth or stud will be brought against one side or the other of the bit or stud on the bolt, and the key will be thereby prevented from going around any farther.

The tooth also serves to hold the barrel and curtain in the proper position to receive the key, as unless some precaution of this kind were taken, the curtain might accidentally slip round and close the keyhole.

One of the methods adopted by the patentee for preventing the curtain from slipping round accidentally consists in causing the tooth to take into a notch in a block that is attached to the upper part of the upper most lever. By this arrangement the patentee states he is enabled to relieve the shield from the friction to which it has hitherto been subjected. Sometimes he surrounds the cylindrical guard or barrel ***a*** with a small spiral spring.

A modification of the above plan of holding the barrel and curtain in its place consists in making an indentation, ***h*** (figure 256) in the periphery of the curtain, in which rests a projecting point on the front edge of the upper lever. The key is prevented from being turned in the wrong direction by the tooth on the curtain, as in the former instance. Instead of abutting against the bit or stud on the bolt, there is a moveable stop-piece, ***I***, which is secured to the plate of the lock by means of two screws, but may be moved up or down by the tooth whenever the bolt of the lock is moved up or down by the key.

Another modification of holding the curtain in its place consists in making the top lever ***e***, with a point which takes into a notch in the periphery of the curtain at ***h***, figure 256, which by abutting against one or the other of the studs or pins on the bolt, prevent the key from being turned in the wrong direction.

Another mode of preventing the curtain from moving accidentally is effected by means of a ***v***-nosed spring, represented by ***j***, figure 257, which is affixed to the inside of the cap-plate of the lock (which in the figure is removed to show the position of the spring), and bearing against the edge of the curtain as it is moved round; so that when the latter is brought into the proper position for removing the key, either when the lock is open or closed, the lower end of the spring ***j*** will enter into the notch ***h***, on the periphery of the curtain, and hold it in its proper position.

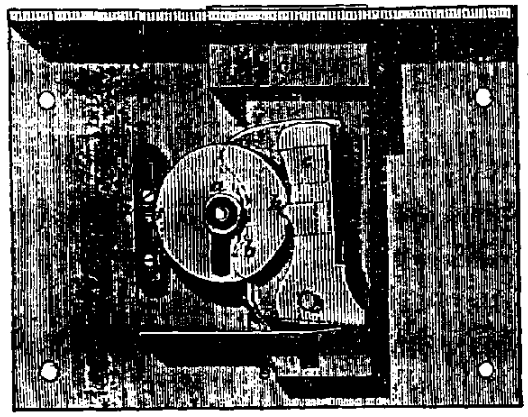

Figure 257. - Restells Lock.

All these modes of keeping the barrel and curtain in its true position are similar to, if not identical with, the notch in the collar or curtain of Mallet's lock, into which fell a lever-bolt.

Another improvement by the same inventor consists of a simple means of so altering the combinations of the levers with the bolt, that the original key, when the alteration is made, will not open the lock. This object is effected without altering the position or combination of the levers, in relation to one another, by simply making the bit or stud of the bolt moveable.

The bit or stud, instead of being fixed to the bolt in the usual way, is secured to a small moveable plate. Two holes are made in the bolt, in either of which the bit or stud may be inserted, and made to project through the levers. A recess is made in the back-plate of the lock to receive the plate, and when the bit or stud is inserted in its place in one of the holes of the bolt, the plate is secured by means of a sliding-plate or shutter.

When it is required to spoil the combination and render the original key useless, it will only be necessary to open the shutter and remove the bit from one hole to the other in the bolt. The effect of this alteration will be that, in order to allow the bit to pass freely through the gates of the levers, and thereby permit the bolt to be shot, the levers must be raised to a different height to that which was before required. Consequently, a different key must be employed to produce this effect.

In constructing locks with this improvement adapted thereto, the patentee proposes to make three keys, two for the first combination and one for the second. If one key belonging to the

first combination should be lost, the lock may be opened with the fellow key, and then the combination spoiled by raising the shutter and moving the plate and bit from one hole to the other; which being done, it will be found that the third key only will open and close the lock; and therefore the other two keys will be useless.

In order to prevent the bolt from moving while the position of the bit is being changed, a small pin may be attached to the lower part of the bolt, and made to enter a notch in the lowest lever, or that nearest the bolt, so as to prevent the bolt from shifting its position.

The same effect, that is, spoiling the combination, may be produced by mounting the pin ***m***, figure 256, on which the levers turn, on a moveable plate. The bit ***d*** will, in this case, of course be fixed to the bolt as usual. The pin ***m*** being attached to a moveable plate, such as that shown at ***k***, will be caused to project through a slot or hole in the back-plate of the lock, precisely as in the former instance. It will therefore be evident, that to alter the combination, by changing the position of the lever, it will only be necessary to shift the position of the moveable plate which carries the pin ***m.***

This patentee is also the inventor of a method of altering the combination in a Bramah lock, by means of a moveable plate.

In reference to lever locks, the patentee states that, besides preventing a person from introducing more than one instrument at a time, he further proposes to prevent any person from feeling the position of the levers by pressing the bit against them, as has usually been the case.

Hitherto the bolt has been held in its place by the levers, as the bit of the bolt was made to nearly fit the notches in the lever. Therefore by forcing the bolt back, and causing the bit to press against the face of the notches in the levers, the latter might be held in any given position, and the obstruction they would offer to opening the lock might then be felt and possibly removed.

The patentee, however, constructs the lock in such a manner that the bit cannot be brought to bear against the levers, so as to retain them in any given position. As it is not necessary that the bit should fit the notches of the levers, the notches are cut much larger than usual, so as to leave a considerable space

between the bit and the face of the notch.

In order to prevent the bolt from shifting its position, except when acted on by the key, the lower edge of the bolt is provided with a tooth or pin, which bears against the periphery of the cylindrical guard, and thereby prevents the bolt from being moved either way, until the guard is turned by the key. A notch therein is brought round, so as to permit the tooth to pass.

A modification of the latter mode is as follows: At the lower end of the barrel ***a*** (figure 256) is fixed a circular plate, which is made to fit into curved recesses cut in the lower edge of bolt ***c***. The bolt is thereby prevented from moving until the notch comes round and allows the points, which are equivalent to the tooth before mentioned, to enter the notch. The key enters the notch in the bolt, and, provided the levers are brought into a proper position, the bolt can then be shot.

Another mode of preventing anyone from feeling the position of the levers is effected by forming an additional notch in the face of the levers. One lever (say the lowermost one) is made a little longer than the others. A small pin is fixed in the side of the bolt. When the proper key is used to open the lock, the levers will be raised in such a manner as to admit this pin through the front gate of the levers.

If a false key or other instrument is introduced, and the bolt pressed back thereby, the pin will be brought against the end of the lowermost or longest lever, and retain the same. Upon discovering the obstruction, and finding all the other levers free, any person attempting to pick the lock will necessarily be obliged to move the obstruction out of the way by raising that lever. Immediately as this is done, the pressure being still on the bolt, the pin will pass into the notches of the other levers, and thereby prevent them from being raised until all are set free again.

The claims set forth in the specification are, first, the combination of the cylindrical curtain or guard ***a*** with the circular shield ***b***, and mode of applying the same, as herein shown and described, particularly the employment of a pin, tooth, notch, spring, or other analogous contrivance, adapted to the circular shield ***b***, together with the other necessary parts connected therewith, whereby the curtain or guard and circular shield may be held in their proper positions, and prevented from slipping round accidentally when the key is withdrawn from the

lock.

Secondly, the employment of pins, studs, or projecting points, adapted either to the circular shield or other part of the lock, whereby the key may be prevented from being turned in the wrong direction.

Thirdly, the use of the moveable plate ***k***, and bit or pin ***d*** or any mere modification thereof, whereby the position of the bit ***d*** in relation to the notches in the levers ***e***, or the position of the levers ***e***, in relation to the bit ***d***, may be altered when required and the combination of the several parts of the lock may be so changed as to render the original key useless for opening the lock.

Fourthly, constructing the bolt with a tooth, pin, or projecting point at its lower edge, which, by bearing against the sides of the cylindrical shield, circular plate, or other suitable part, will prevent the bolt from being shot until a suitable notch, cavity, or opening, made for the purpose in the said cylindrical shield, circular plate, or other part, is brought round, so that the tooth, pin, or projecting point on the bolt may enter therein, and allow the bolt to be moved.

Fifthly, the use of the moveable plate and its moveable bridge-piece or bracket, as applied to a Bramah lock, for the purpose of changing the relative position of certain parts of the lock.

Sixthly, constructing the levers with an additional notch at the end, into which a pin, secured to the bolt, will enter upon applying force or pressure thereto. By thus holding all the levers, will prevent any of them from being raised until the bolt is thrown back again.

Seventhly, the use of a protector-lever, which lever is by means of a pin connected to the circular shield, kept raised too high to allow the bolt to be shot, and cannot be allowed to descend until the circular plate is moved round and the keyhole closed.

Eighthly, the method of constructing a mortise lever lock, which can be opened by the key from either side, the keyhole being protected with double shields.

Ninthly, the method of constructing tumbler latches, as shown in the drawings attached to the specifications.

HOBBS' PROTECTED LOCK, patent dated February 23, 1852.

The patentee, in his specifications, states that, "My invention relates to a novel mode of constructing certain parts of locks, by means of which the possibility of feeling the position of the gating of the levers by applying pressure to the bolt is prevented."

"Another part of my invention consists in a novel arrangement or construction of parts, whereby the key or instrument which operates upon the levers to bring them into a proper position, preparatory to throwing the bolt, is carried into the lock, and the keyhole is effectively closed while the key or other instrument is so acting upon the levers."

"This lock in its general appearance resembles the usual lever locks. It has the same form of key and the same moveable parts.

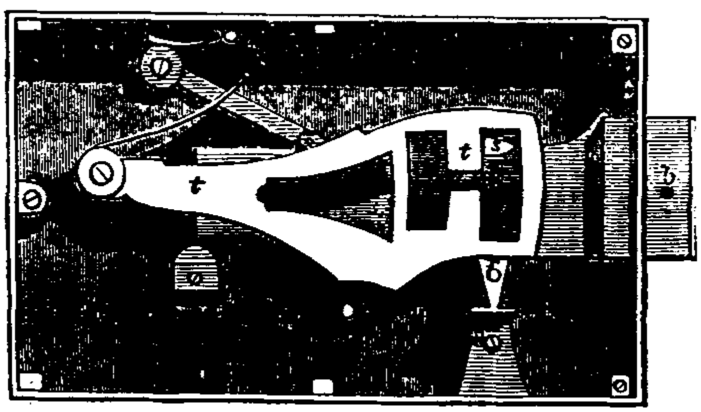

Figure 256. Hobbs' Protector Lock.

The only addition being attached to the ***tumbler stump***, which addition works under the bolt of the lock. Figure 258 represents the mechanism of this lock. "**bb**" is the bolt. "**tt**" the levers, with the usual slots or gatings, through which a tumbler stump **s** must necessarily pass when the bolt is being locked or unlocked.

In all other locks this ***stump*** is riveted into the bolt. Consequently any pressure being applied, or an attempt made to withdraw the bolt, brings the ***stump*** against the face of the levers, causing them to bind, by which means the gatings are easily found. In this lock, on the contrary, the stump ***s*** is

riveted into a piece shown detached in figure 259.

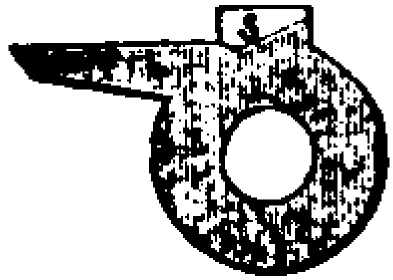

Figure 259.

The hole ***h*** is fitted on a center pin in a recess formed at the back of the bolt. The stump passing through a slot in the bolt, stands in its usual position. There is a small binding-spring to prevent the piece from turning of itself.

When the key is applied to the lock and the levers properly adjusted, the stump, meeting with no obstruction, passes through the gating of the levers. But should an attempt be made to withdraw the bolt before the levers are all properly raised, the stump, meeting with the slightest resistance, turns the piece to which it is attached on its center and raises the portion of the piece ***p*** so that it comes into contact with a stud, riveted into the case of the lock, thereby preventing the possibility of withdrawing the bolt, and at the same time releasing the levers from any pressure, so that it is impossible to ascertain their proper position.

D is a dog, or lever, catching into the top of the bolt, serving as an additional security against its being forced back. **K** is the 'drill pin' on which the key, figure 260, turns.

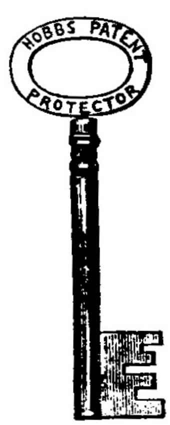

Figure 260.

R is a piece on which the levers rest. Although, by this simple addition, and without adding materially to the cost, locks are rendered perfectly secure against picking, or being opened by any instrument except the true key or its duplicates, yet as with all other locks where the key is not susceptible of change, any person having had the key in his possession may, by taking an impression, become master of the lock. For purposes of absolute security this danger is effectively guarded against by the ***permutating or changeable key locks."***

The claims set forth in the specification are:

First, the use and application of a moveable stump to the bolt, or attaching a moveable piece to the stump, or the stump to a moveable piece, for the purpose above described, and shown in the several figures in sheet No. 1.[1]

(535)

Secondly, the use of a compound or double lever, as shown in figures 9 and 10, sheet No. 1, for the purpose above described.

Thirdly, the arrangement shown in sheet No. 2, figures 1 and 2, or any modification thereof, either by circular parallel motion, by which the bit of the key is carried into the lock and made to operate upon the levers. This will bring them into a suitable position, preparatory to shooting back the bolt, the keyhole being completely closed while the key-bit is operating upon the levers.

Fourthly, the constructing of a lock, with a bolt having a series of right angular slots, moving both vertically and horizontally, operating with a single set of slides or levers, as shown in sheet No. 2, figures 6,7,8, or any modification of the same for the purposes before named.

Mr. Hobbs is also the inventor of a "flush-bolt portable or camp-desk lock." The specification states in reference thereto that, "The advantages of this lock over those in general use are these; that the bolt descends flush with the selvage when the lock is unlocked and when in the act of locking first ascends vertically from out of the selvage, until it arrives at the proper height of the link, then, with a horizontal motion, slides under the link, as in the ordinary method of the common link-plate lock."

The movement in this latter lock is precisely the same as that in Perry's. Numerous efforts have been made to construct a ***simple flush-bolt lock,*** and the most successful of any we have seen is one to be described hereafter, and is the invention of Mr. Aubin, Nettlefold's patent of 1855.

TUCKERS CLOSED-KEYHOLE DETECTOR LOCK, patent dated October 1st, 1852.

The separating-key lock of this inventor (previously described) was found to be objectionable, from the possibility of the accidental severance and consequent loss of the key-bit. The present lock was produced as possessing equal advantages in point of security, while at any rate free from that special objection to the key which had tended mainly to nullify the commercial value of his previous invention. The same principle of "closing up all communication with the security parts" while "pressure" can be produced against them is also eliminated in this lock, and is carried into operation as follows:

The lock presents two ***external*** key openings, through one of which, ***F*** (figure 263) the ***true or grated keyhole*** can be seen. This grated keyhole is situated in a drum, ***H***, placed close behind the front-plate **J**, and rotating parallel with it, and forms the sole inlet to the interior mechanism. The keyhole ***E*** leads to a central sink or chamber in the drum, into which the key must be inserted, or in which a handle may be fixed, in order to give the requisite rotation to the drum, but which chamber offers no communication with the internal mechanism of the lock.

Figure 261.

By this arrangement, and by the manner in which the sliders **D** (the action of which is from front to back, as in a Bramah lock) are situated relatively to the locking-plate **G**, the effect of non-communication with them from the keyhole, while they are in

contact with the locking-plate, is produced.

These sliders are placed in two chambers in, and slide parallel with, the axis of the drum, immediately behind the true keyhole, the locking-plate being fixed at such a distance from them when the bolt is thrown that they, together with the keyhole, must be carried behind the front plate and *covered over entirely,* before they can be brought into contact with it, access to them being then impossible.

The tentative process of picking being thus rendered inoperative, security against "ringing the changes" was next provided for (to use the words of his specification) as follows:

By the adoption of a new principle of detection, whereby all further attempts to pick the lock are entirely prevented, should previous trials to effect it have been to a certain point successful, and this is carried into effect by a pin or bolt (**I**, figure 262) springing from the circumference of the drum, which flies into a hole in the lock-frame so soon as certain of the combination sliders have been sufficiently advanced to pass the face of the opposing (locking) plate, when, should the remaining sliders be incorrectly adjusted, the drum can neither be advanced nor retrograded, so that no further attempts to pick the lock can be made.

As in this lock the key-steps only impinge on the *ends* of the sliders, there is no *difference* in the impressions made by *long* and *short* steps, consequently "mapping" the sliders is impossible. It was equally impossible with the previous lock.

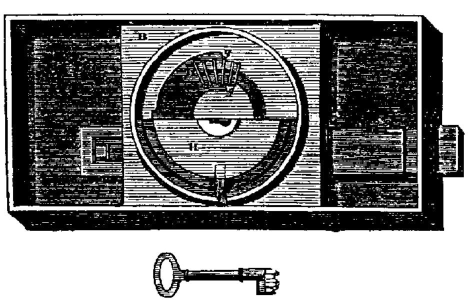

Figure 262.

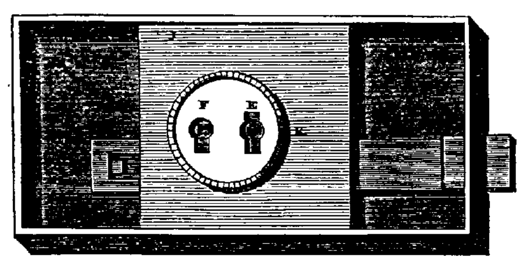

figure 263.

The remaining feature of importance in this lock consisted in the mode of making the frame or case, the body of which was cast *solid,* leaving only sufficient space in it for the revolution of the drum and the passage of the bolt; the front and back plates

being screwed to the solid body.

The purposes contemplated by this mode of making the case were strength and cheapness of manufacture, and security from injury by gunpowder. The idea of a *"solid* powder-proof lock" was indeed so effectively carried out in it, that in a full-size bank lock on this plan there was not sufficient vacant room for half-of-powder, and for that little, even a vent was provided at the back of the lock.

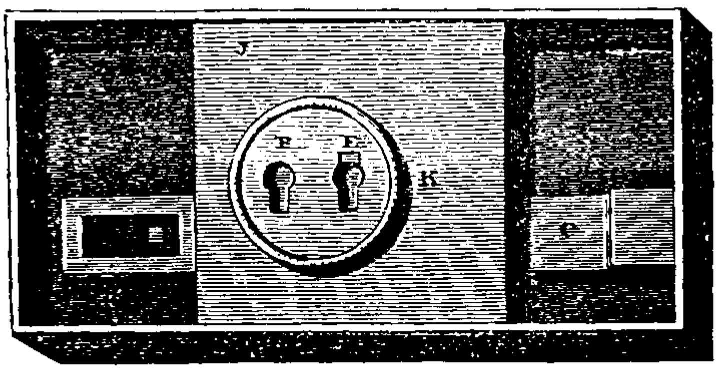

Figure. 264

This mode of making the lock-case has been since patented by Mr. Milner, and so closely imitated him that with the exception of the vacant space for the insertion of powder in his lock, being many times greater than in the original lock, and that Mr. Milner's contains no vent for the escape of the powder. it would puzzle a nice observer to find the difference between them.

ROSE'S Lock, Patent dated October 21st, 1852.

The object of the inventor of this lock was to produce a lock which could not be picked, and he sought to effect it as follows:

The lock is of the ordinary lever kind, and at the back of the levers are two strong springs, one spring for each lever. The pin upon which the back-ends of the levers work is inserted into the short arm of a bell crank, whose fulcrum is fitted to the frame of the lock, immediately above the pin on which the back-ends of the levers work; the long arm of the lever is prolonged parallel with the bolt, and terminates in a projecting piece corresponding with a slot made in the top of the bolt of the lock.

On any attempt being made to force back the bolt, the short arm of the bell-crank lever would be carried back, and the long arm

with its projecting piece would be brought down, and would effectively prevent the bolt being pressed back by the projecting piece fitting into the slot or aperture made for its reception in the bolt.

On pressure being withdrawn from the bolt, the springs would force back the levers, and with them the short arm of the lever, and consequently raise the projecting piece on its long arm out of the slot in the bolt, and thus leave it in a fit state to be opened by the proper key of the lock.

The claim is for "improvements in locks, whereby the bolt is prevented from being forced back, as herein-before described."

CHUBB'S LOCKS, containing the improvements patented by John Chubb, November 1st, 1852; and John Chubb and John Goater, January 21st, 1853.

The following description of Chubb's *modern* locks we here copy from Mr. Tomlinson's book, it having been furnished by Mr. Chubb to the editor of that work for insertion therein. We applied to Mr. Chubb for a similar description, but did not receive any reply:

Lock No. 1. "The first of the improvements introduced consists of a barrel, to which a circular curtain is attached, revolving round the drill-pin in the lock; so that if any instrument is introduced to attempt to pick it, the curtain immediately closes up the keyhole and prevents the introduction of any auxiliary instruments, there being several required in action at once to produce any effect."

"If by any means these several instruments can be introduced simultaneously, the barrel keeps them all confined in a very small space, preventing their expansion, and renders it impossible to work them independently of each other; therefore they are of no avail, being incapable of acting as more than a single pick, which is perfectly useless. The barrel and curtain have each been previously used *separately* in locks, but until patented by Mr. De la Fons in 1848 they had not been used in *combination.*"

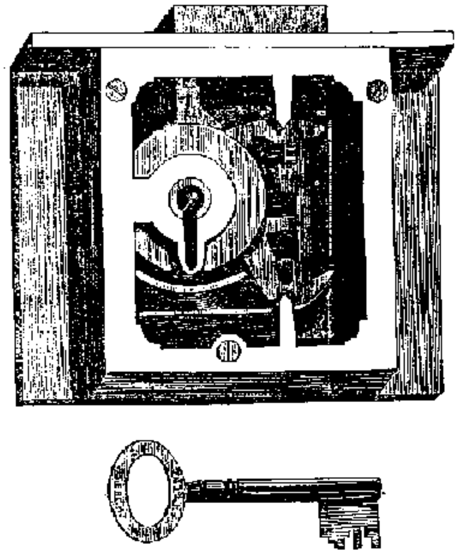

Figure 265.—Chubb's Detector Lock of 1856.

Neither of them used separately is of much use, but when combined they afford a very great security. Locks have been, and still are shown containing either the barrel or curtain *singly;* and as these have been picked, it has been asserted that the improvement now introduced in Chubb's lock is equally insecure, but a slight examination of the difference in their construction will prove the contrary. Mr. Chubb has *purchased* the patent-right of this part of Mr. De la Fons' invention, and applies it to all his locks.

Lock No. 2. "The next improvement, recently patented by Mr. Chubb, is based upon the assumption the security of the barrel and curtain as already described (although this assumption is not in the slightest degree admitted), and consists in applying what is called a 'tumbler-bolt,' working on a hinge connected with the main-bolt. The web of the key does not in any case touch the main-bolt in unlocking, but acts only on the tumbler-bolt.

All the tumblers must first be lifted, each to its proper position, before the tumbler-bolt will act. Should any pressure be applied to either bolt before the tumblers are all at their exact position, the effect would be to throw the bolts out of gear, and thus effectively to stop the stump of the main-bolt from passing through the racks of the tumblers. None of the many plans of picking which have been suggested, such as smoked key-blanks, thin key-bits, etc. would be of the least avail against a lock made on this principle.

Different kinds of detectors may be applied to these locks. It is submitted that this lock, retaining all the simplicity and durability which have distinguished Chubb's lock for so many years, and combining with them these important improvements, affords a complete security against all surreptitious attempts of any nature. Locks on the same principle are being made on the permutation plan, with any number of tumblers, and any number of changes in combination that may be desired.

"It has been suggested that the 'detector,' instead of giving additional security to Chubb's lock, affords a partial guidance to a person attempting to pick it. This objection holds good to a certain extent in these locks as originally made, in which all the tumblers had an *equal* bearing against the detector-stump; but in the locks as now constructed, this objection is entirely obviated by giving the tumblers an *unequal* bearing, whereby, if an operator feels the obstruction of the detector-stump, he cannot tell whether the tumbler which he is lifting is raised too high, or not high enough."

"**Lock No. 3**. For banks, Mr. Chubb has introduced what he particularly calls his 'bank lock.' It contains a barrel with a series of curtains. While the keyhole is open, all access to the tumblers from the keyhole is completely cut off by two sliding-pieces of solid metal, which fit closely on either side of the barrel. These pieces are acted upon by an eccentric motion, so that when the key is applied to the lock and turned in it, the keyhole is shut up by the revolution of the curtains, and then only do the sliding-pieces of metal move aside **I**, to allow the key to act upon on the tumblers."

These pieces return to their position when the key has passed; therefore, while the key is lifting the tumblers, all communication is cut off from the exterior of the lock by these sliding-pieces and the series of curtains. The bolt is made in two pieces, the main-bolt never being in contact with the key, which acts only on the talon-bolt, and by it transmits the motion to the main-bolt.

After the action of locking, the talon-bolt is partly repelled, and a lever or 'dog' connected with it locks into a series of combinations arranged upon the front parts of the tumblers, and holds them securely down, so that none of them can be lifted in the least degree until the talon-bolt is thrown forward to release them. If, therefore, any pressure be applied to this

talon, to endeavor by its help to ascertain the combinations of the tumblers, it will only the more tightly lock them down, and render the attempt ineffectual.

By another contrivance, it is rendered impracticable to move a pick or picks round in the lock more than a small distance, unless the tumblers could previously be all lifted to their right positions, which can only be done by the right key. Should one or more of the tumblers be surrepitiously raised by any possible means, they cannot be detained in this uplifted position, for the action of turning back the pick to try to raise another tumbler sets in motion a lever which allows the tumblers already raised to drop to their former position, leaving the operator just as far from the attainment of his object as at the outset."

From the foregoing description of Mr. Chubb's *modern* locks, it would appear that he places great reliance upon the security against picking when the barrel and curtain combined forms part of the construction of a lock; but it must always be borne in mind that wherever the key can go, there also can a picking instrument. We attach the same amount of importance to the adoption of the barrel and curtain combined as we do to the use of the various kinds of detectors; and we recommend all future inventors of locks to aim at constructing them in such a manner that they may be perfectly secure without the aid of such questionable friends.

An objection has been made by some against the use of those lever locks, the keys of which are stepped, and the lowest of which steps usually moves the bolt. They say that by grinding or rubbing off a portion of the step in question, whilst the proprietor's back is turned only for a few moments, a dishonest *employee* may open his master's safe or other depository and commit a robbery, and the employer not know in what manner the robbery has been effected, for no marks of violence are necessary to the successful operation. We admit the thing is just possible; at the same time no thief would attempt a robbery by such means when he could effect his object more certainly and in less time by taking an impression of the key.

The *rationale* of the above plan is as follows: From what we have previously stated in former chapters, it will be understood that in lever and tumbler locks the lowest or bottom step on the key-bit usually moves the bolt by coming in contact with its talon. Now if to throw the bolt quite out, that is to lock the lock, requires the step to be, say, 5/8” long, it follows that if

1/8” were rubbed off and the same key applied, the **bolt** would not be shot in the same proportion, although the key performed its revolution.

The consequence would be that the stump of the bolt would remain in the main-gating of the levers instead of in the rack nearest their center of motion, the true position; and it will therefore be apparent that if when in such a position the operator went to the lock with a key having only the bottom step on its shank, it would move back the bolt without the slightest difficulty, because the levers could not offer any obstruction to its motion.

We have never heard of a robbery having been effected by this means, neither do we think a *thief* would ever adopt it. It must also be borne in mind that with a *hardened* key, it is not an easy matter to reduce a step of the bit even the sixteenth of an inch by rubbing it with oil and emery.

In the Chubb's lock shown in figure 265, a contrivance has been introduced for the purpose of preventing a lock being tampered with in the manner above described, which consists in placing a guard on the bolt, so that the next longest step of the key-bit will move the bolt, instead of the terminal step coming in contact with the talon in the ordinary way; but we do not consider this plan by any means effective or desirable.

WHISHAW'S MAGNETIC Lock Patent dated January 29, 1853.

The patentee states in his specification that his invention to consist in locking the locks of doors, safes, etc. by means of electromagnetism. To the door-frame or casing, as the case may be, is attached an electromagnet of sufficient power, which, as is well known, is produced by passing a current of electricity by means of properly insulated wires (coiled round the soft iron) in connection with a galvanic battery.

The electromagnet is let flush into the frame or casing of the door, so as not to be visible externally; the poles of such magnet are made perfectly smooth and even throughout, so as to admit of a uniform surface for the end of the iron bolt (or any suitable lock which may be fixed on the door, or a simple iron bolt alone will answer the purpose) to abut against, in order that when the surface of the end of the bolt is in contact with the poles of the magnet, (provided the electric circuit is complete,) the electromagnetic locking is perfected; but immediately on the circuit being broken the electromagnetic lock

is unfastened, and, in the case of an ordinary lock, the security will then depend simply on the bolt being shot into its keeper. As many locks as there are electromagnets and ordinary locks included in the circuit can be secured by this invention.

JENNINGS LOCK, Patent dated January 29th, 1853.

This invention has reference to a new construction of lock, in which a series of permutation plates, each pierced with a central hole to receive the key, are arranged within a cylinder or other case furnished with a projection to receive the action of the key, and with a recess or recesses in the outer periphery to receive a lever when all of them have been brought round to the proper point.

The key is made of a series of plates corresponding in number with the permutation plates, and each having a recess of different length to act in succession on the permutation plates to bring them to the proper position for the reception of the levers, one of the series of plates being cam-formed for the purpose of operating the lever.

The permutation plates and lever are arranged within a rotary cylinder or other case, surrounded by a permanent flanch or case properly recessed for the reception of the lever when held out by the permutation plates, to prevent the said rotating case from turning when locked. Combined with the rotating cylinder or case which contains the permutation plates and lever is an eccentric fitted to a yoke on the bolt for the purpose of throwing the bolt, the eccentric being at the dead point when the bolt is thrown out, so that any pressure applied directly to the bolt to force it in may have no tendency to turn the eccentric.

It will be obvious that the key, instead of being made of separate plates, may be cut out of a solid piece of metal, but this will not present the advantage of changing the combination.

SIMSON'S DUPLEX BANK LOCK, Patent dated May 2, 1853.

This lock, which is the invention of Mr. Willlam Simson, banker, Edinburgh, has combined with it the "detainer" claimed by Mr. Gibbons in his patent, dated December 22nd, 1853.

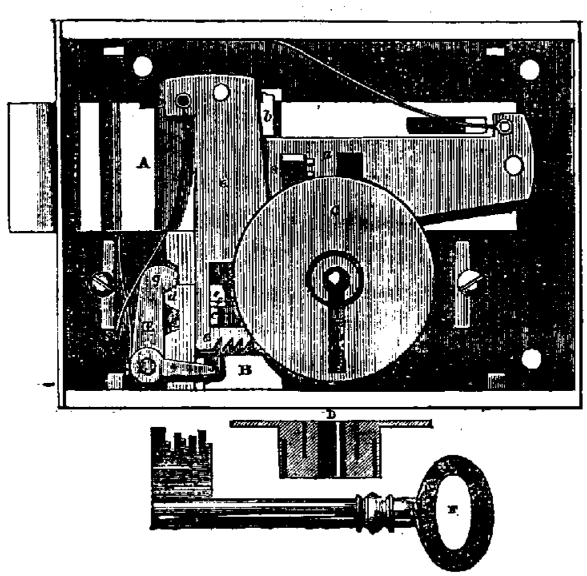

Figure 266. Simson's Duplex Bank Lock.

Figure 266 represents the combined lock, and the following description is taken from the published prospectus of it.

"Into this lock are introduced the following new parts or mechanism:

1. Simson's patent double set of bolts, each with its separate springs and levers. The ordinary horizontal-bolt, **A**, is crossed beneath at a right angle by another bolt, **B**, with its own set of levers, **e**. The vertical-bolt, **B**, is not shot beyond the case of the lock. It is brought down with a lateral projection, **b**, fitted to a notch in the horizontal bolt to hold it fast, and to shut down the horizontal-levers, **a**. This combination renders it impossible either to lift the latter or to force back the former until the vertical bolt has been raised again. The two sets of bolts and levers vary, each having its own notch in the bit of the key.

Each set consists of four levers: there are thus in every lock eight levers, giving upwards of 2,400,000 different combinations. The key cannot be taken out of the lock until the vertical-bolt has secured the horizontal-bolt. The horizontal-levers being shut down by the vertical-bolt, their range or lift cannot be felt from the keyhole. The required liberation of both bolts is effected by one turn of the key. In locking, also, one turn of the key first throws out the horizontal-bolt, and then brings the vertical-bolt down upon it.

2. Simson's patent curtain or block, **c**, adapted to the circuit of the key, acting as a protector to the wards, levers, and bolts of the lock, and moving round with the key when turned.

"The sides are grooved to fit the wards, as shown in Section **D**, and the edge overlaps to some extent the bolts and levers, thereby more than fully closing up the keyhole as soon as the key is slightly turned. The wards, by this arrangement, are vastly elevated in importance, and lose their character of an easily destructible security; and in proportion as the protector fills up space, which is usually left vacant, it prevents the application of gunpowder to destroy the lock; and it excludes dust, thereby keeping the works for a longer time unclogged."

3. Gibbons' patent detainer, **E**, applied to the vertical-levers, rendering it necessary to lift them all simultaneously to their true position, and effectively securing them against having that position ascertained by raising them one by one.

"The vertical-bolt **B** is retained in its proper place, when locked, by the lowest lever, **f**, which has its face close to the stump, **c**, of that bolt. The other levers, **c**, have a series of notches cut in their ends, and have their faces, **e**, set back, so that when the lowest lever, **f**, is adjusted, the bolt can be moved a little distance before the stump, **c**, reaches them."

Upon the adjustment of the lowest lever, **f**, a slight motion given to the bolt, **B**, causes the beveled edge, **d**, of it to act upon the detainer, by pushing up its beveled end, **g**, thereby bringing down the other end, **h**, which is pointed, into the notches cut in the ends of the levers, thus fixing them firmly in whatever position they may be at the time such motion is given to the bolt.

The true key forms the complete combination, by lifting every one of the levers correctly before it begins to move the bolt; but should any one of the levers, **e**, be put out of its proper position by a false key or picker, the act of moving the bolt carrying its stump from the face of the lowest lever, **f**, to the faces of the other levers, **i**, causes the detainer to fix such lever in that wrong position, and it will be impossible for the operator to tell which lever it is that prevents the opening of the lock, or whether it does so by being above or below its true lift.

"He can pretty accurately ascertain the difficulties he has to overcome in attempting to open an ordinary lever lock without its proper key, and he is able to adjust his instruments accordingly; but this detainer shuts out from him the means of arriving at an opinion as to the requisite lift of the levers, and leaves him quite at fault."

We are sorry we cannot compliment Mr. Simson on the originality of his invention, as the double set of levers was introduced by Mr. Duce, in 1824, as described earlier; and the "curtain or block," as we have before shown, has been reinvented over and over again. The size of the lock allows the limbs to be made very strong, and the number of combinations obtained by the number of levers presents a great obstacle to its being picked either by the tentative process or by ringing the changes. Like all other bank locks, its high price will prevent its being adopted for general purposes. The locks we have seen, which were made by Mr. Gibbons, are thoroughly well made.

PARNELL'S SECOND LOCK, Patent dated September 9th, 1853.

This lock is constructed with levers, supported on a pin or fulcrum placed at or near the center of the levers instead of the end, as in the ordinary lever locks. There is a notch at the outer end of the levers to receive the lock-stop, and another notch at the opposite end of the lever to receive the detector-stop. Upon the outer end of each of the levers (or it may be in any other convenient part) are formed two inclined planes, and springs are placed in such a position as to be capable of acting upon either incline, so as to move the levers in opposite directions.

When the bolt is shot, the springs pressing upon the inclines force the levers against the locking-stop, so as to retain it in the notch; but if an attempt be made to pick the lock, the moment any of the levers are lifted too high, the pressure of the corresponding spring becomes transferred to the incline of that lever, and the lever is thereby forced into contact with the detector-stop, which enters the notch in the lever, and is retained therein by the pressure of the spring upon the incline. There is also a horizontal-stop acting against the butt end of the levers when the bolt is shot out.

The claim is for supporting the tumblers or levers upon a central axis, the arrangement for maintaining a tumbler in contact with the detector-stop after the withdrawal of a false key, and the

horizontal-stop.

TUCKER'S SAFE GUARD LOCK, Patent dated Nov. 21st, 1853.

Mr. Tucker, finding that his *closed keyhole lock;* described subsequently in this text, was still open to the objection of requiring a two-fold operation of the key to unlock it, the present lock was invented to supply its place. The same *principle* of security is adopted in this as in the former lock, it being equally impossible to obtain access to the security parts while pressure could be maintained upon them as in the closed keyhole lock, but the mechanical construction of this lock is very dissimilar.

The security parts are here formed as circular or wheel-shaped levers, arranged upon a central pin; these levers are surrounded or enclosed in a moveable box or barrel with an opening in its side, which opening is the *true* or *internal* keyhole (there being but one *external* keyhole) through which alone can communication with the levers be obtained.

As it is only when this internal keyhole is carried behind a fixed shield or safe-guard in the lock (so that no communication with it from the external is possible) that the bolt or security-stump can be brought into contact with the levers. It is manifest, therefore, that all attempts at picking by the pressure or tentative process must prove abortive.

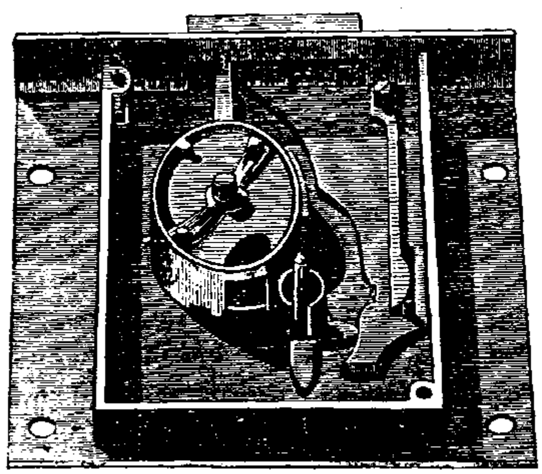

Figure 267. Tucker's Safe-Guard Lock.

The requisite motion is given to the surrounding box by an auxiliary key-bit attached to a socket (surrounding the

drill-pin, and reaching the whole depth of the lock), into which the key fits, and carries with it the socket and auxiliary-bit in its revolution. The drill-pin or axis of the key is fixed beyond or without the line of action of the moveable box, the talon of the bolt upon which the bit operates being still further beyond it.

The action is thus: The key is placed into the outer keyhole and turned round, carrying the auxiliary-bit with it; the key-bit first passes into the internal keyhole in the side of the box, adjusting the levers to their true position, whilst a simultaneous movement is being given to the box; the action of the key being pursued, it then passes out *of the internal keyhole,* the auxiliary-bit continuing the movement of the box and carrying the internal keyhole behind the fixed safe-guard or shield, so that no communication with the levers can be effected; by which time, and not until then, a gating in the side of the box being brought into a line with the bolt-stump, the bolt can be drawn back.

In the reverse or locking action, the first effect of the action of the key, when put in motion, is to lock out the bolt, carrying the bolt-stump out from the box; by continuing the action, the auxiliary-bit operates on the box, reopening the internal keyhole and forcing the levers back into their normal positions, so that neither dirt nor viscid oil can prevent their action.

The part of the levers on which the key-bit impinges is so shaped that the key-steps can only impinge on a projecting point or nib, by which means, *be the steps of the key acting on the levers either long or short, the amount of smoke they remove shall in each case be the same.* This peculiar formation of the lever is claimed by the inventor as a means of preventing the possibility of " mapping" the levers. Another advantage claimed by him also as arising from the use of the auxiliary-bit to throw the bolt is that no fraudulent shortening of the terminal of the key-bit can prevent the bolt from being fully thrown, or the levers being restored to their correct locked positions behind the stump.

GIBBONS' DETENT LOCK, Patent dated December 22nd, 1853.

The improvement effected in this lock consists in the introduction of a *detainer* or *lever-fixer* the use of which is to fix the levers in one position before the stump of the bolt comes in contact with them. The lever next to the bolt is made with its face to project beyond the other levers, so that when the bolt is

locked out, the stump of the bolt is retained in its proper position by this lever, which the inventor calls the "locking-lever."

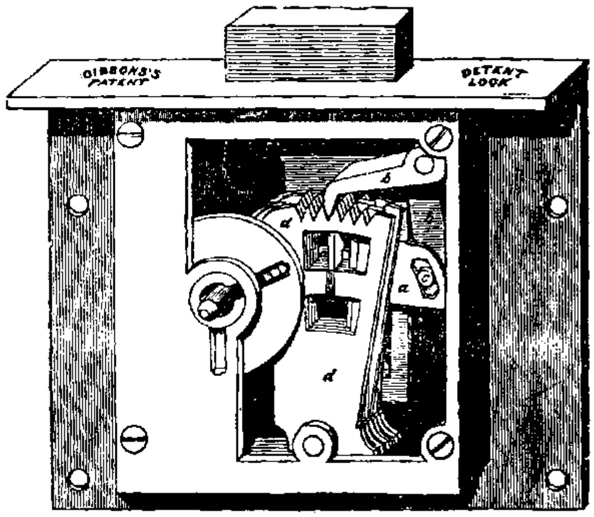

Figure 268. Gibbons' Detent Lock.

Figure 268 represents the lock. ***a*** *is* the locking lever; ***d*** the other levers, which are set back, so that in unlocking, the lever ***a*** must be raised to allow the stump of the bolt to enter its gating, when it moves along some distance before it comes to the face of the levers ***d.*** The act of lifting the lever ***a*** causes it to raise the arm of the detainer **b**, which is connected with it by the pin **c** and this brings the point of the detainer into the notches formed in the ends of the levers ***d,*** as shown in the cut.

By this means, the levers ***d*** become firmly fixed or detained in their position, and are incapable of any further adjustment until the stump of the bolt comes in contact with them. The true key lifts all the notched levers **d** to their true position before it acts upon the locking-lever **a**; the detainer **b** is then brought into action, and the levers as represented in the cut offer no obstruction to the passage of the bolt.

Should any one of the levers **d** be either **above or below** the true lift, at the time the lever ***a*** *is* lifted, the detainer will fix it in that particular position; the face of the lever will oppose the passage of the stump of the bolt, which renders it impossible to open the lock, or even to tell which lever it is that causes the obstruction, and whether it arises from its being above or below its true position. This lock is constructed with a curtain

and one deep ward or wheel, as shown in the key, figure 269.

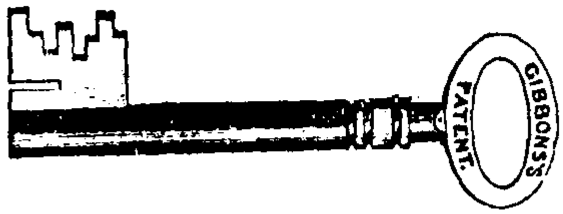

Figure 269. The Key.

The above construction makes it impossible to pick the lock by applying pressure to the bolt, and the true lift of the levers cannot be ascertained by raising them separately. The lock can only be opened by simultaneously raising all the levers to their true position, which can only be done by the true key.

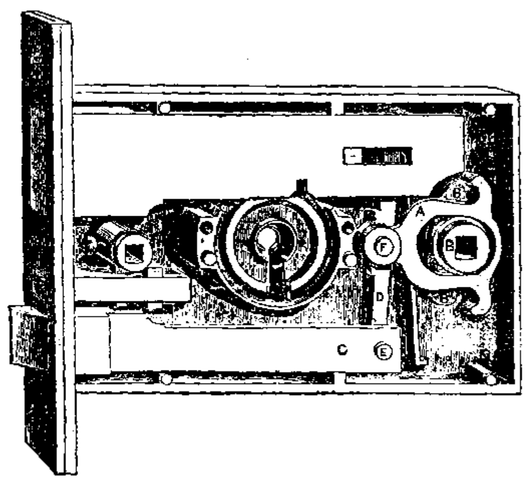

Figure 270. Gibbons ANTI-FRICTION LATCH-BOLT

Another improvement by the same inventor is shown in figure 270, which represents a mortise lock. The improvement consists in using a loose tail-piece, **A**, to connect the follow **B** with the latch-bolt **C** by means of a guide **D**. The guide **D** works at its upper end upon a circular pin or axis affixed to the plate of the lock, its lower end being connected with the latch-bolt **C** by a pin **E**, and with the tail-piece **A** by a center-pin **F**. The upper and lower extremities of the follows, as well as their corresponding recesses in the horns of the tail-piece **A**, are of a semi-circular form, the consequence of which is, that on turning the knob in either direction, a rolling action takes place between the surfaces in contact with it; the ordinary friction is thus avoided, and a perfectly smooth, easy, and durable action is

obtained.

When turned to its full extent, the follow is stopped by the tail-piece coming in contact with the end of the lock, thus making it impossible to strain the guide or to bend the tail of the bolt, defects to which the common latch-bolt is well known to be liable. The position of the follow, which is placed very near to the end of the lock, allows the greatest possible space between the knob and the keyhole, which in small-sized locks is a most important advantage.

SAXBY'S LOCK, invented 1853.

The interior of this lock consists of a cylinder with four pins or slides radiating from the center, and pressed into the keyhole by means of spiral springs. The pins project beyond the periphery of the wheel or cylinder, and into slots in a ring which is affixed to the case of the lock, thereby preventing the cylinder from being turned. On each pin is a notch, so placed that when the proper key is inserted into the keyhole, the notches on the several pins will be brought into a position such as will allow the cylinder to turn. The turning of the cylinder in this, as in the Bramah lock, shoots the bolt.

This lock is the same in principle, but not so secure in its construction, as the Yale lock described at earlier.. The inventor was rewarded by the Society of Arts with the Society's medal and the sum of ten guineas; and shortly afterwards the lock was picked by Mr. Hobbs, "in the presence of parties connected with the Society, in the short space of three minutes." We shall refer to this circumstance again in the next chapter.

DENISON'S LOCK, Invented 1853.

This lock is the invention of E. B. Denison, Esq., Q.C., (whose name is better known in connection with clock-making), and was exhibited at the Society of Arts with others, when the Society made the unlucky mistake of selecting for its premium a lock which, as above stated, Mr. Hobbs picked in three minutes, and which was also proved to contain nothing new in its construction.

Figure 271 represents Mr. Denison's lock with the bolt shot and the levers **t t** thrown, so that the bolt evidently cannot be drawn back until they are moved into the proper position for the stump to enter the gating.

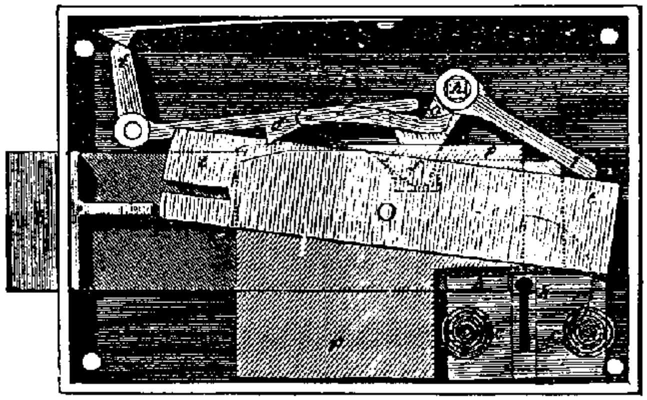

Figure 271. Denison Lock

One of its peculiarities is that there are no lever springs. The levers turn on a pin near the middle, so that they will stand indifferently in any position, especially as they are separated by thin plates, **p p**, which cannot turn. In this lock, therefore, the friction, which is usually an impediment, and sometimes obstructs the action of the springs, is an advantage. The first plate should be between the bolt and the first lever, and no plate is required between the last lever and the cap of the lock.

The plates should slip easily onto the lever-pin, and one or two of them should be bent a little, so that when the cap is on, they will act as friction springs, and increase the steadiness of the levers. It is easy to see that when a proper key is put into the keyhole **k** and turned half round, it will raise the levers into the position in which the stump of the bolt can enter them, and the bolt can be drawn back.

But the bolt is never acted on by the key, which may consequently be very thin and light, as it has nothing to do except raising the levers. The bolt is worked by a handle, **h**, which has a fantail projection, **f**, working in a notch in the bolt, and also another broad lever, **L**, which pushes down the ends of the levers nearest the keyhole as soon as it has shot the bolt.

The key, therefore, is not required at all to lock the lock, but only to open it; differing therein from the large safe locks, in which the bolts are shot by a handle, which are locked by the key afterwards. At the same time it is more secure than any of the self-shutting or spring locks, which are, moreover, apt to get shut accidentally when not intended.

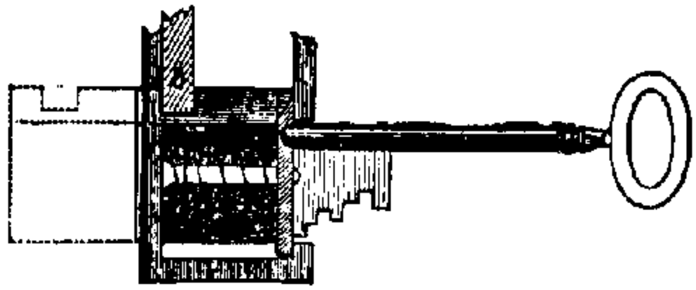

Figure 272. The Key.

It is admitted in the *Rudimentary Treatise an Locks,* edited by Mr. Tomlinson, and published in 1853, that this lock cannot be picked by any known method, for the following reason: when the bolt is fully shot the stump is a little beyond the end of the levers, as is shown in the figure, and the keyhole is completely closed by a steel curtain, **c c**, which cannot be pushed in by the key or any other instrument, except when the bolt is fully shot and the stump removed beyond the possibility of contact with the levers; and therefore the tentative method, before described, of feeling the pressure of the stump on the levers cannot be used.

The curtain **c c** (shown also in figure 272) slides on two pins with spiral-springs behind it, and has a square plug which pushes through the back of the lock, as dotted in figure 272. This plug has a notch in it which exactly coincides with the bolt **b** when the curtain is up against the keyhole, so that the curtain cannot be pushed in except when the bolt is fully shot (as in figure 271); and then, when the curtain-plug is pushed down by the key ever so little, the bolt cannot be drawn back at all so as to feel the stump against the levers.

One of the levers has its end above the gating elongated a little to keep the bolt steady when shot, and in advance of the curtain-plug. The key is solid without a pipe, which further diminishes its size; the key of a large lock with seven levers weighs not much more than a quarter of an ounce.

There is a further provision to guard against the bolt being shot, either carelessly by the owner or intentionally by somebody else, without turning the handle far enough to depress the levers and fix the bolt. **d i** is a lever turning on a pin just above the bolt, and working on a spring at **s** like Chubb's detector, or what is called a jumper in clock-work.

For convenience this may also be called the detector; and it will

be seen that when the corner **i** is on the right hand of the jumper **s**, the tooth **d** will fall into one of the notches of the bolt as soon as it is shot about three-quarters of the full distance; and then the bolt cannot be drawn back again until it has been fully shot and the handle turned far enough to depress the levers, when a projecting corner of the fantail **f** will raise the detector and make it pass the jumper, which will hold it up as now shown in the drawing. As the bolt is drawn back again in unlocking, a pin in the fantail catches hold of a piece set on the top of the detector, and brings it down again to be ready for action.

The advantages of this lock are therefore these:

First: Perfect security, at least against any known method of picking;

Secondly: A keyhole so small that no forcing instrument strong enough to do any mischief can be got in;

Thirdly: Protection of the lock by the curtain from the effects of the atmosphere upon the works;

Fourthly: Impossibility of getting deranged by the levers sticking together, or by failure of lever springs, there being none;

Fifthly: Cheapness of construction compared with any other lock equally secure and strong;

Sixthly: Lightness and smallness of the key;

Seventhly: The convenience and safety of not having to use the key for shutting the lock.

This invention is not patented, Mr. Denison being one of those who disapprove of patents. A somewhat different form of it for small locks is described in the *Rudimentary Treatise* before mentioned; but it does not appear likely to come into use for furniture or small articles, where the handle would probably be objected to; and the difference in the size of the key and the price of the lock, compared with other locks, is not so great as in large and strong locks for safes and articles of that kind.

GIBBONS' DOUBLE-DETECTOR LOCK, Patent dated 1853.

This lock contains a new element of security, it being so

constructed that not only will the over-lifting of any one of the levers throw the detector; but should any attempt be made to move the bolt without having first sufficiently raised all the levers, the detector will be brought into action by the under-lift as well as the over-lift of any one of the levers.

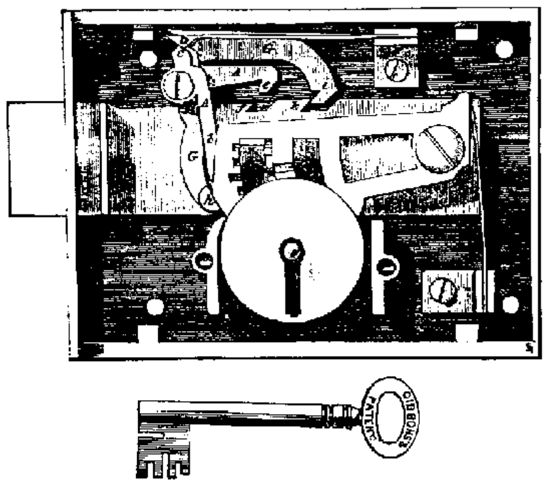

Figure 273. Gibbons' Double-Detector Lock.

When any of the levers are raised above their true position, the arm **b** of the detector **A** is brought forward, and the arm **e** hooks into the bolt at **f**; the v-nosed spring **D**, acting upon the point **c**, keeps it in that position.

The under-lift detector **G** has its arm **i** slightly hooked into the bolt at **k**. When the levers are lifted by the true key the point **i** rises out of the bolt; but should any attempt be made to move the bolt when any of the levers are below their true position, the levers will keep down the detector by pressing upon it at **h**, and the beveled edge of the bolt at **k** will draw down the detector at **i**, where it will be *fixed* by the spring **D.** In cases where a detector lock is required, these locks will be found very superior to the ordinary detector locks, which act by the over-lift only.

DANIEL'S IMPROVEMENTS, Patent dated February 1st, 1854.

These improvements, consist, first, in applying to one-bolted locks a slide, on which the follow acts, and on which is fixed the tumbler and tumbler spring, connecting the slide with a bolt answering as lock and latch-bolt, and which bolt will act by being placed under, upon, by the side, or end to end with the

slide, or in other positions, as different forms of locks may require it to be placed.

By means of this slide the double action of the latch is obtained, that is, admits of the handles turning either way, and allows the same bolt to be locked out with the key, dispensing with the use of a second lever or tumbler, and other complicated parts hitherto applied to attain the double action in one-bolted locks; it has also the advantage of being very durable.

Secondly: In casting the cases of locks with suitable bearings and holes for the bolts, tumblers, and other parts to act in, in the construction of locks containing one, two, or more bolts;

Thirdly: In applying a certain method in the formation of the patterns used for casting lock cases, which dispenses with the laying in of cores for forming the bolt-holes;

Fourthly: In employing a click inserted into the neck of the knob, which acts into racks formed in the spindle by tightening or slackening a screw in the neck of the knob; the neck consisting of an inner and outer neck, the inner neck being of cast iron or other suitable metal.

TANN'S LOCK, Patent dated March 2nd 1854.

The patentee, in his specification, states that, “This invention consists in an improved mode of constructing certain parts of locks, for the purpose of rendering such instruments more secure than the locks as heretofore constructed, and in known and common use; and this invention relates more particularly to those descriptions of locks known and distinguished as 'tumbler locks.'

The mode heretofore practiced in constructing locks of the most modern, and, up to the present time, allowed to be of the most improved construction, namely, those known as Hobbs' patent, has been to make the 'stump' or that part which is employed to hold the bolt of the lock (when shot outwards) in such a position as to prevent or to render difficult the drawing back of such said bolt with any pick or instrument other than the key designed and specially intended to be employed for such purpose; and further, a peculiar feature in the construction of the aforesaid locks has been to arrange and dispose the aforesaid stump with respect to the other parts of the lock in such manner as that it is independent of the bolt of the lock, instead of being affixed to such said bolt, as heretofore generally practiced in the

construction of locks, and particularly those known and distinguished as Barron's, Chubb's, and other patent locks.

The object and intention of making such said stump independent of the bolt has been to take the end pressure off the bolt, and thereby to render ineffectual any attempt to force back the bolt for the purpose of causing the aforesaid stump to press against the tumblers of the lock, and by which such said tumblers would hang, and thereby facilitate the raising thereof, and the ultimate unlocking or picking of the lock by instruments other than the key thereof.

Now, it is to be particularly understood that the principle of construction of this invention consists in, and is entirely dependent upon, and will only act, so as to afford additional security to the lock when end-pressure is exerted upon the bolt, instead of the pressure being required to be taken off the bolt, as before stated, with reference to Hobbs' locks.

This I effect by constructing locks in the following manner, that is to say: I employ a bolt, in which a stump is fixed, which works in the 'gates' of the several tumblers in the manner commonly practiced, excepting that (for the purposes of this invention) I construct and arrange that tumbler which is in immediate contact with the bolt (and which I call a locking or holding-tumbler) in such manner that this tumbler only receives the pressure from the stump of the bolt, by which I take off the pressure from the other tumblers, and thus prevent them from hanging when raised by any instrument other than the key of the lock.

I employ a separate spring, acting upon the tail-end of the said locking or holding-tumbler, for the purpose of raising the front end of such said tumbler when the other tumblers are raised by the action of the key thereon, and when there is no end pressure upon the bolt, observing that the aforesaid locking or holding-tumbler, by being acted on by the aforesaid spring only, is entirely self-acting, and is not in any way operated upon by the key of the lock.

It is only when end-pressure is exerted upon the bolt (as commonly practiced in picking locks) that this tumbler becomes locked or held, and does not therefore rise with the other tumblers, and the locking or holding of this one tumbler in particular: arises from the pressure of the stump against the edge of the gate of this tumbler being greater than the pressure

of the spring upon the tail end of such said tumbler.

Thus it will be seen that so long as the end-pressure remains upon the bolt of the lock, such bolt cannot be drawn back, but immediately such pressure is removed the spring acts, and the locking or holding-tumbler then rises; and I protect this tumbler from being acted upon by a pick or other like instrument, by forming a rebate upon the bolt of the lock, below the edge of the said tumbler; and I also place a shield beneath the under-edges of most of the other tumblers, so as to present an obstruction to the introduction of a pick or other like instrument.

I declare this invention to consist in so constructing certain parts of locks as that I render available the end pressure upon the bolt for the purpose of attaining greater security in locks than heretofore; whereas the principle of construction of the modern locks, before mentioned, consists in removing the pressure from the bolt for the purpose of affording such security.

TANN’S NEW PATENT BANK LOCK.

Figure 274 represents “'Tann’s’ New Patent Bank lock," which, with the following description, are taken from the patentee's published prospectus. The figure shows the lock with the cap-plate and nozzle or chamber removed:

First: The tail end of the bolt is formed of two plates, placed one over the other, the upper or rising-plate forming the talon. These are hinged together at one end, with a slot at the other, so that if any force or pressure is applied to the talon before the tumblers are raised, the effect of any such pressure causing the top-plate to rise, immediately detecting the lock; and the slot catching against the back-stump entirely takes off the pressure of the levers from the tumbler-stump, so that the levers will not hang or indicate the height of the gating;

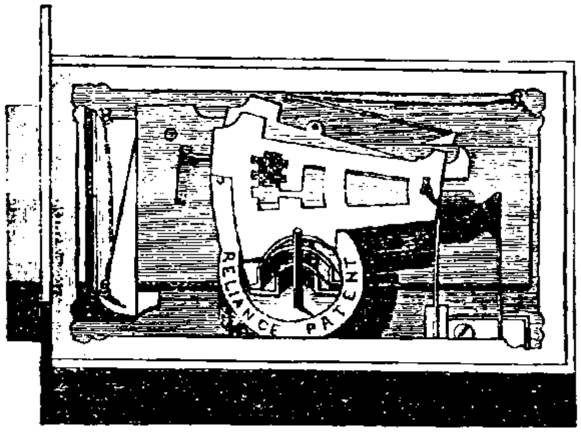

Figure 274. Tann's "New Patent Bank Lock."

Secondly: Relieving the main-stump from the pressure of the levers, so that if force is applied to the bolt, the levers will not hang or indicate the height of the gating, through which the main-stump passes; and this is effected by a self-acting lever, working in the bolt and not operated on by the key.

Supposing force was applied to the bolt for the purpose of picking or opening the lock by any other instrument than the key, the effect of such force would be to cause the self-acting lever to hold in the bolt, and thus take the pressure of the stump from the levers, and it remains fixed until such force is removed; consequently the very pressure, so fatal to other locks, in this affords additional security, and prevents the possibility of its being opened.

Thirdly: Protecting the levers by guards. (From the many thousands of lever locks that have been made, all of similar construction, it follows of necessity that many of them must be alike, and consequently pass each other).

The guards form an entirely new feature both in the arrangement of the lock and key, and effectively shut out the keys of all other patent locks. The guards are placed on several of the levers, and protect the levers either above or below them, so that even if a false key or pick succeeded in lifting the levers with unprotected fronts, it could not possibly raise those behind the guards, and the slightest extra lift at once fixes the detector, and then the proper key only can regulate it.

Fourthly: The cylindrical nozzle affixed to the outside of the face-plate of the lock, in which is a solid circular piece of

hardened metal, with a keyhole cut at right angles with the keyhole in the face-plate of the lock, so that when the key is inserted the keyhole in the nozzle is opposite to the one cut in the metal.

The keyhole in the faceplate being closed, the revolving metal in the nozzle is then turned by the action of the key, and brought opposite the keyhole in the face-plate, at the same time closing up the aperture by which the key entered the nozzle, so as to always present a closed keyhole, whether the key is in or out of the lock. Thus it will be seen that the keyholes in the face-plate of the lock and the nozzle not being opposite to each other, both can never be uncovered at the same tine, and thus render impossible the introduction of any picking instruments.

We may remark that the nozzle forms a distinct chamber, and in consequence doubles the thickness of the lock, which makes it look clumsy. This nozzle or chamber is for other reasons very objectionable. The construction is similar to the chambered locks described in chapter 15, and therefore possesses no novelty.

YOUNG'S LOCK, Patent dated June 12th, 1804.

This invention consists of an improved detector lock, and a latch to be applied to the same and other locks. Figure 275 is a representation of the lock. **a a a** are the levers, which differ from ordinary levers in having teeth, ***b,*** on their ends, by which the picking of the lock, by forcing back the bolt so as to feel the levers, is prevented; the end **c**^{1} of the slide **c**, on the lever ***d,*** which is fixed on the bolt, engaging in such case in the teeth ***b,*** and frustrating the attempt.

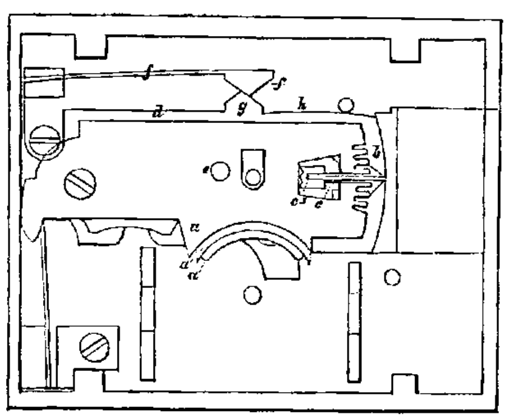

Figure 275-Young s Lock.

The lever ***d*** *is* in two parts, the part carrying the slide **c** turning upon a point **e**, shown in dotted lines upon the other part. When the bolt is shot, the spring **f** pressing upon the part **g**, causes the end **h** of the lever ***d*** to rise, and until it is brought down again by the action of the key into a horizontal position the bolt cannot be withdrawn.

If a false key be introduced, and it brings the lever **d** past the horizontal position, the point **g** of the said lever passes to the side **f** of the spring, which no longer tends to bring back the lever **d**, but to keep it in its displaced condition.

The introduction of the true key detects the displacement of the lever **d**, and corrects it in a way the patentee does not consider it necessary to describe.

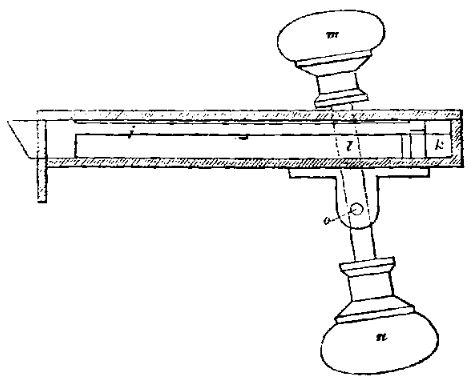

Figure 276. Young's Latch.

The improved latch to be used with the above or any other lock is shown in the horizontal section, figure 276, **i** is the latch-bolt, urged forward by the spring **k**, the said latch is withdrawn by a lever 1, turning upon the point **o**. The knobs **m n** are moved by a sliding motion, instead of the usual rotary motion.

Mr. Young is also the inventor of what he calls the "Palace Motion" to locks and latches. Figure 277 represents a three-bolt mortise lock, with steel follow, brass collar, wards, etc. **A** is the lock-bolt; **B** the private bolt; **C** the latch or spring-bolt; **D** the follow; **E** the latch-lever; **F** its center-pin; **G** a pin on which is suspended the latch; **H** the spring. The latch is drawn into the lock by the crank of the follow bearing against the lever at **I**.

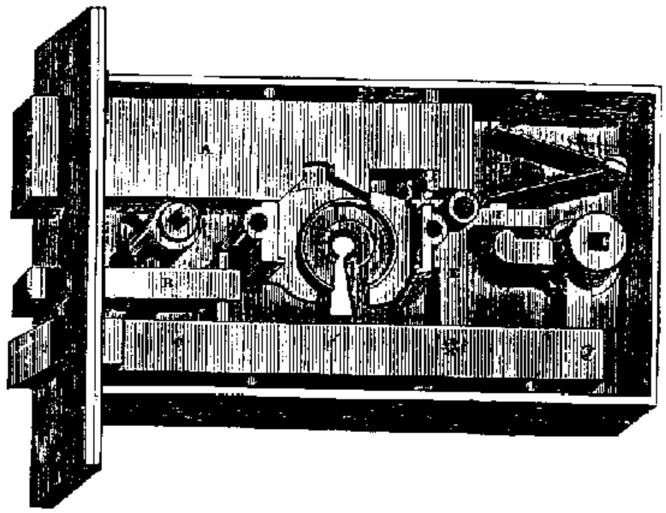

Figure 277. Young's Palace Motion Three-Bolt Mortise Lock.

Reverse the turn of the follow, and the latch will be drawn into the lock by the straight-arm of the follow pressing against the pin on the latch at **J**.

WOLVERSON'S LOCK, Patent dated July 11th, 1854.

This lock is constructed with a series of plates on the end of the bolt, which are capable of sliding vertically; these plates are pressed downwards by springs. There is a slot made in a horizontal direction in each of the said plates; and after the bolt of the lock has been shot, it can only be withdrawn by the said plates being made to slide vertically to the several heights required to bring their respective slots opposite each; for a plate situated at the back of the lock prevents the slot being withdrawn, unless the said plate can enter the said slots.

The several plates on the bolt are raised to the necessary heights in the following manner: Immediately over the keyhole in the interior of the lock are a series of slides, which by the motion of the key are raised to different heights; these slides have projections on their sides, which, when the bolt is shot, engage under projections on the sides of the first mentioned sliding-plates.

The first action of the key is to raise the slides, these raise the plates on the bolt to the necessary height to permit of the bolt being withdrawn; the plates on the bolt are held in their position during the motion of the bolt by clicks engaging in

teeth on their edges. When the bolt is shot, the said clicks coming against a fixed obstacle are disengaged from the plates, which are pressed down by their springs.

MILES' LOCK, Patent dated August 4th, 1854

The patentee, in his specification, states that in the construction of this lock, any number of levers may be used according to circumstances, *each combined with its own spring,* for which purpose brass will be found suitable, so that for marine and other similar purposes the objectionable use of steel or iron in any portion of the lock can be avoided.

A lever, called 'the regulator,' is also introduced, which has a different motion from the others, being without a spring attached to it. It receives the pressure from the springs of the other levers, and in case of any attempt at picking, it reacts upon them, and produces such a combination of difficulties as must insure the highest amount of safety in the lock.

This inventor is one of the few who have taken the right course with respect to the improving of locks, but he did not go far enough. He evidently understood the desirability of making the springs of a metal that would not rust; and this idea has since been fully and successfully carried out by Mr. Aubin in not only making the spring of the lever of brass, but also making it *out of one and the same piece of metal.*

LEWIS'S LOCK, Patent dated September 2nd, 1854.

This lock is constructed with two knife-edged stumps attached to the head of the bolt of the lock, with one knife-edged or flat stump fixed to the lock-case at the tail-end of the bolt. There are also double-acting levers, having notches at the ends, corresponding with the stumps just described. When any other key than the proper one is used to open the lock, or pressure is applied for the purpose of picking it, the stumps drop into their corresponding notches, and at the same time the lever closes the keyhole.

NEWTON'S LOCK, invented by L. M. Eiler, of Copenhagen, Patent dated October 3rd, 1854.

The object of this invention of improvements in the construction of locks, is to dispense with the use of a key and consequently obviate the necessity of having any keyhole, or other opening,

whereby access may be obtained to the interior of the lock with any instrument whatever.

Instead of employing a key or other analogous instrument provided with wards, pins, or other equivalent contrivances for bringing the several internal and moveable parts of the lock into their proper position for shooting the bolt back for opening the lock; this object is effected by means of the power of a magnet. The foundation-plate of the lock must of course be made of some metal, such as brass or copper, which is not capable of affecting or being affected by the magnetic influence of a permanent or other magnet.

On the inner side of this plate are made a series of grooves or channels, arranged and combined in any arbitrary manner. In these grooves or channels are made to work a series of iron or steel slides, which must be capable of moving within the grooves, and should be so arranged that they cannot be moved except in a given and prearranged order and succession.

When the bolt of the lock is shot forward, one of these slides or pieces is brought up behind it in such a position that it cannot be moved back until the slide has been first removed, and this cannot be done until all the other moveable pieces are brought in succession into their proper positions.

These moveable pieces or slides must be moved by the power of a magnet applied at the back of the copper or brass plate, and which will be sufficiently powerful to attract and move the small slides inside when it is applied immediately above them. As three, four, or any number of these small pieces or slides may be combined and arranged in any preconceived manner, it follows that unless a person wishing to open the lock knows precisely the position, arrangement, and combination of the parts, he cannot bring these parts into their proper places, and consequently will not be able to open the lock.

The proprietor must provide himself with a plan, showing the position of the pieces, and with this before him he will have no difficulty, by the aid of a powerful magnet, to draw back the slides in their proper order, so as to leave the bolt free to move back.

In locks where a trifling additional expense is not an object, and great security is required, this may be obtained by the application of one or more permutation-plates, whereby the

combination or arrangement of the internal parts may be changed at any time with facility. Several bolts may be adapted to the lock, if required, and these may be so arranged that they must be moved in some prearranged order. For instance, they may be marked letters to form a particular word, and unless moved in their proper order the lock will not open.

WENHAMS LETTER LOCK, invented 1854

This is an improved letter lock constructed on a new detached principle, and is the invention of Mr. F. H. Wenham, of Effra Vale Lodge, Brixton, Surrey. It can only be picked by ringing the changes.

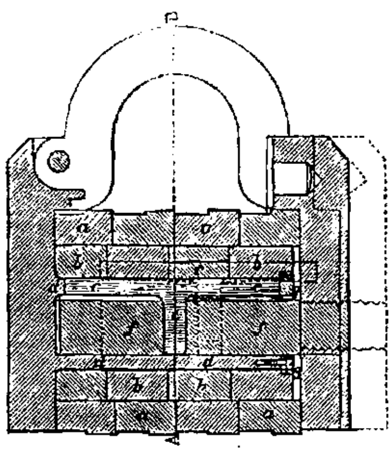

Figure 278--Wenham's Letter lock.

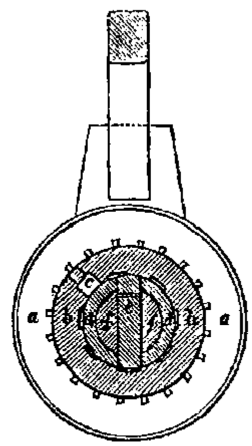

Figure 279.—Section at A 11.

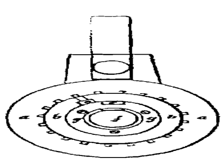
In the following drawings the same letters of reference apply to each of the figures: **a a**, figures 278, 279 and 280, are letter-rings; **b b** under or stud-rings, having one deep notch shown at **c c**, and several very shallow false notches seen in the transverse section, figure 279. **d d**, is the central tube upon which the rings turn. This is cut through on one side with a longitudinal groove to admit the T piece **e e**. The stem of this slides in a hole at right angles in the draw-bolt **f f** and is forced upwards by two springs or elastic strips, cut from its own material, as seen on its under side.

When the T-piece is down in its groove, it abuts against the collar **g**, and holds the bolt back in its place; but when the deep notches (indicated by the selected letters on the outer shifting rings) are brought in a line over the T-piece, it springs up so that its end can pass above the edge of the collar **g**, and allow the bolt to be drawn.

If a force is put upon the bolt, it is *impossible* to open the lock, even if the right letters are hit upon, for the T-piece in this case becomes jammed against the collar and held as if in a vice, and consequently cannot rise unless the pressure is removed.



It is therefore evident that in opening this lock, no attempt must be made to draw the bolt *before* the proper letters are placed in a line, thus at once removing all possibility of picking by what is known as the "pressure principle."

So long as a pressure is maintained upon the bolt it remains *absolutely impregnable,* as even the proper letters will not be available; and as the usual method of picking by feeling cannot be brought into operation, the only chance is to attempt to work through the permutations, which no one conversant with the subject would think of doing.

The use of the shallow false notches in the stud-rings is to prevent the possibility of opening the lock by hearing, for if the stud-rings had but only one or two notches, the cessation of sound (caused by the slight friction of the T-piece) when it arrived at the gap or notch, might indicate the proper letters; but the interruption of sound caused by the shallow notches quite remedies this objection.

Figure 281 represents the center stud-ring. This has its notch cut away in an inclined direction, as shown; this is for the purpose of forcing the T-piece down again into its groove when the lock is to be closed, by means of the inclined plane being carried round by turning the ring. If all the notches were square, the rings could not be made to turn when the T-piece was up and the lock could not be shut.

This lock was exhibited at the Society of Arts in 1854, and obtained for its inventor the Society's bronze medal.

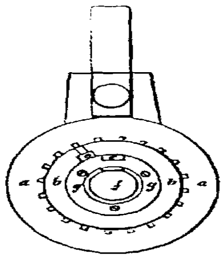


Figure 280.—End View, with the cap unscrewed from the bolt and removed.

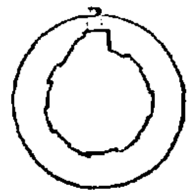

Figure 281.Centre-Stud Ring.

WOLVERSON s LOCK invented about 1854.

The peculiarity in the construction of this lock consists in the delicate poising of the detector, by which it is rendered very susceptible of motion. Also the curves of the steps of the key-bit are made irregularly, some almost flat, others elliptical. There are also two sets of levers; the key when turned round in the lock touches the first set, which gives motion to the second or compound levers, until they reach the point of unlocking, but they do not then stand in the same *relative position* as at starting, a certain distance having been gained by some, in consequence of the irregularity of the curves.

In restoring the detector to its place, the levers assume a new form or motion, and are at a different elevation from that required to unlock; hence all information gained after the detector has been thrown, which would probably take place at the first touch, would be of no use whatsoever.

The delicate poising of the detector and the compounding of the levers in this lock is identical with Aubin's compound-lever lock, invented in 1851, and described earlier.

BELLFORD'S LOCK:, Patent dated April 25, 1855.

This lock is for sliding doors; the peculiarity of the construction consists in combining a catch with a sliding bolt. The inventor, in his specification, states that the casing of the lock may be of rectangular form, in which there is a sliding bolt working on a stump, the said stump passing through a slot in the bolt. Between the bolt and the casing there is a guard-tumbler; one end of this tumbler works on the said stump, and the opposite end is provided with a projection, against the back side of which a pin on the bolt catches when the bolt is thrown forward.

There are two springs fixed on the casing, one of which acts upon

the bolt and the other upon the guard-tumbler. Just below the bolt there is a catch, the inner end of which works on a pivot; the outer end passes through a slot or opening in the side of the casing, the said slot being sufficiently long to allow the outer end of the sliding bolt to pass through. To one side of the framing of the door there is secured a slotted bar, and a mortise is made in the framing over which the bar is secured, the lower edge of the slot in the bar being some distance above the lower edge of the mortise.

When the door is closed, the lower or inclined edge at the outer end of the catch strikes against the lower edge of the slot in the bar, and the catch passes through the slot, and is forced down over the lower edge of the said slot by the spring, which acts upon both the bolt and catch.

The key is then inserted in the keyhole and turned, and the guard-tumbler is first raised, so that the projection will be raised from the pin attached to the bolt; the key then throws the outer end of the bolt through the slot in the bar, and the catch is thereby prevented from being raised until the bar is thrown back. The catch is operated upon by a knob in the usual manner.

HENDERSON'S LOCK, Patent dated May 11th, 1855

This invention relates to a peculiar construction and arrangement of certain parts of locks, whereby they are rendered less liable to be opened with a pick or false key. The improvements consist in adapting to the outside of the face-plate a species of auxiliary lock, which requires to be first opened before the keyhole of the main lock can be entered by the key.

This auxiliary lock is composed of a number of concentric wards and concentric split rings, which work around the pipe of the lock in the spaces between the concentric wards. The whole is covered by a shield and outside casing, so that when the key is out, the keyhole is perfectly closed. An additional ward is fitted inside the main lock round the pipe, a sufficient amount of space only being allowed between the outside of the pipe and the inside of the ward equal to the thickness of the metal of the pipe of the key.

In opening this lock by the proper key, the key is first inserted into the auxiliary lock in a reversed position to that which it must assume before it can enter the main lock, the keyhole of which is suitably situated, and entirely concealed by the

concentric rings before mentioned. The splits in each of these rings are all brought around to correspond to the main keyhole by turning the key, whereupon the key is at liberty to enter the main lock, and having entered therein all the concentric rings will be held fixed by a suitable catch until the key is withdrawn again, whereupon on the key coming in contact with the holding-catch, the rings will be released again, and free to turn round with the key before its withdrawal from the auxiliary lock.

The internal concentric ward serves to prevent the possibility of acting upon the main-bolt for the purpose of shooting it whilst the tumblers are held up to the required elevation by other implements.

TUCKER'S HOLDFAST LOCK, Patent dated May 21st, 1855.

This lock was designed by the inventor for the purpose of providing a lock that should offer the same security against picking and fraudulent tampering as the "safe-guard" lock, described earlier, while it should at the same time be more simply and cheaply constructed. The same principle of security is adhered to in this lock also, the ordinary revolving-barrel and curtain being so applied as to prevent the bolt-stump being brought into contact with the slides until the key itself has passed beyond them.

The manner in which this is effected is simply by causing the upper part of the stump or some other pin or projection in the bolt to bear upon the circumference of the curtain in such a way that the stump cannot reach the security-slides until the key (the bit of which is confined in the barrel) is carried so far around as to leave the slides behind it, by which time and not until then, an opening in the curtain presents itself opposite to the stump and allows it to come in contact with the slides, when, if the real key has been used, it will pass into their gatings and the bolt can be upshot.

If, however, a wrong key or false instrument is used, the stump will stop against the slides and "pressure" be produced; but as during the time of such pressure the instrument is carried beyond the slides, and cannot be brought again into contact with them without first driving away the stump and relieving the pressure, it is clear that the tentative process of picking can have no effect upon them. The curtain in this lock serves also to throw the bolt and to force the slides into their correct positions in locking. The slides **b**, figure 282, are horizontal flat pieces of

metal, made to surround the drill-pin entirely, the openings, **c** in them for the revolution of the key being so small as to admit but a very small quantity of gunpowder, by which means in conjunction with spaces in the rim of the cap for its escape on explosion, the lock is rendered powder-proof.

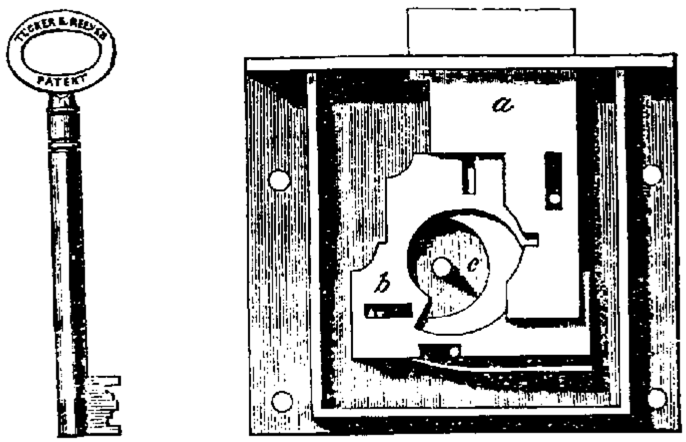

Figure 282--Tucker s Holdfast Lock, with the cap and curtain removed. The Key represents the kind used for iron safe door locks.

The inventor modifies his modes of using the curtain to prevent pressure for various descriptions of locks and latches; for instance, in trunk, portfolio, book-edge, and padlocks, and in all kinds of spring locks and latches, he attaches the stump to the curtain, and causes it to revolve with it, the key being in such cases carried considerably past the action parts of the slides before the stump has traveled far enough to reach their gating-edges. The stump is also in all these kinds of locks made to restore the slides into their proper positions before the key can be removed from the lock.

He also claims a peculiar mode of locking the shackles of padlocks, by which they are rendered much stronger than in the ordinary way. It consists in forming the shackle with a continuation, or tail beyond the joint, such tail being carried into the body of the lock, and in causing the locking of such shackle to be effected at the inner or tail end of it, in place of locking it at the outer or spoon end, as is customary, by which means the usual weakening locking-slot in the spoon end of the shackle is entirely done away with. The curtain itself also forms the bolt in the padlocks under this patent, which still further simplifies the work and lessens the cost of production.

NETTLEFOLD S LOCK, Patent dated June 9th, 1855.

The principal feature in this lock, which is the invention of Mr. Aubin, consists in simplifying the general construction, and by making the levers answer the double purpose of spring and lever. This latter object is effected by making the lever *figure 283 and* ***c****,* figure 284 with its spring, out of one and the same piece of hard metal. The stump, which is usually fixed in the bolt in other locks, in this is fixed into the bottom lever **b**, and this lever when end pressure is applied to the bolt **a**, for the purpose of picking the lock, rises in an *inclined slot,* cut in the lever or in the bolt, as the maker may choose. A hook on the end of this bottom lever grasps a stump fixed in the lock-case.

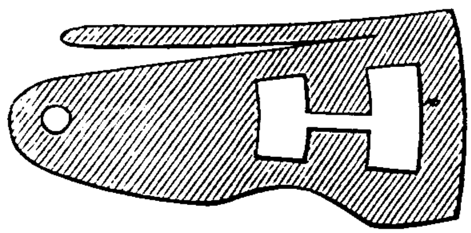

Figure 283. Nettlefold's Lever.

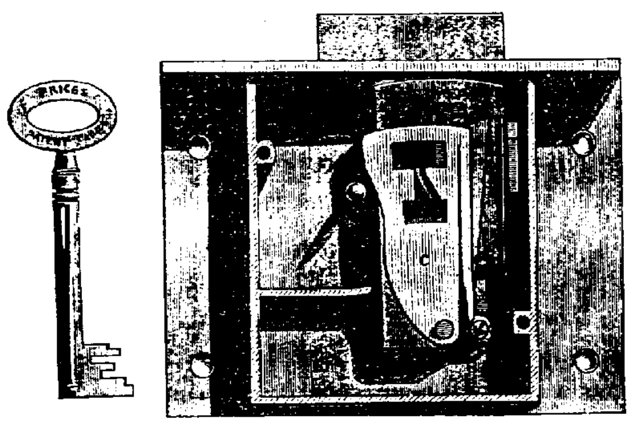

Figure 284--Nettlefold s Lock.

When the bolt is released from pressure, the lever being self-adjusting it regulates itself. The construction of the lock allows the internal parts to be made very strong; and as it cannot be picked by pressure, the security it affords is undoubted. It car, be made into a change or permutating lock at a small additional cost. Another way of constructing it is with an expanding stump, or a stump in two parts, so that when end

pressure is applied to the bolt, the stump opens or expands, and becomes too wide to pass the gating of the levers.

Another improvement consists in constructing the lock with an expanding key chamber, which entirely closes up the keyhole when the key is out of the lock, thus preserving the interior from dust. It makes it also powder-proof.

The great evil in all lever locks hitherto invented has been the tendency of the levers and springs to separate from each other, or the prong of the spring working on to different levers as soon as the lock receives a slight jar. The springs in other locks are made of thin steel; and if from any cause a small speck of rust is produced on any one of them, it is rendered very liable to break, especially in frosty weather. These steel springs, even in the workman's hands, are difficult to keep in their true position, each spring to its own lever, and chamfering the springs and the levers is too often resorted to in order to make them work better, but which in reality renders the lock still more liable to get out of order when fixed.

Mr. Aubin's simple but meritorious lock may be considered to comprise but three moveable pieces or limbs, namely, the key, the bolt, and the bottom lever. False notches, serrated stumps, curtains, deep wheels or wards, and all such like contrivances are altogether unnecessary in this lock, **and where such exist it is an evidence of doubt** as to the real security of the lock on the part of the particular inventors.

Aubin's **pianoforte** lock, constructed on the same principle as the former, is the simplest flush-lock of any yet invented. It requires only one limb to work the bolt, ***a a,*** (figure 285) and is locked and unlocked by an inclined slot working on a pin fixed in the bolt, and which thus forms bolt, lever, and spring made out of one and the same piece of metal. This lock, when fixed on a pianoforte, is perfectly free from any noise or jar incidental to some other locks caused by the vibration of their several parts.

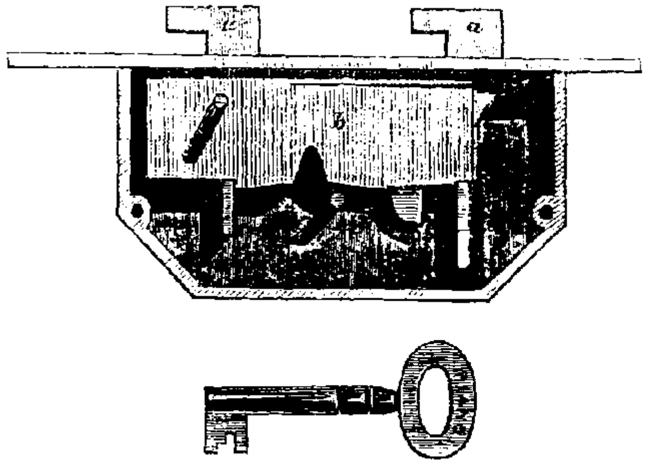

Figure 285. Nettlefold's Flush-bolt Lock.

The claims set forth in the specification are:

First: The moving of the bolt by means of a diagonal slot, or two inclined planes in a sliding-plate acting upon a stud or studs in the bolt.

Secondly: The application to locks of an oscillating-tumbler for moving the bolt.

Thirdly: The forming the levers and their springs in one and the same piece of metal.

Fourthly: The application to locks of an expanding stump.

Fifthly: The application to the bolts of locks of a hanging-plate, carrying a stump, and also a stud which enters an inclined notch in the bolt, so that when end-pressure is applied to the bolt, the inclined face of the notch acting upon the stud throws up the hanging-plate, and prevents the stump from entering the notch in the lever.

Sixthly: The application to locks of two discs carrying two stumps acting upon the bolt, so as to prevent the stump on one of the discs from entering the notch in the lever when end pressure is applied to the bolt.

Seventhly: The application of a sliding-shield operating to prevent access to the levers by means of false keys.

Eighthly: The application to locks of two swinging-pieces,

forming an expanding-chamber.

SCULLY and HEYWOOD'S LOCK, Patent dated July 15th, 1855.

This invention relates to the application to locks and latches of a novel construction of guard for protecting the internal mechanism of the lock or latch from being tampered with, for the purpose of throwing the bolt or lifting the latch. In place of the ordinary keyhole a cylindrical-chamber is formed, through which the key is inserted, and in this chamber is placed and secured a swivel-pin, which is provided with a helical rib or feather, or other lateral projection, which will offer an obstacle to the insertion of a key other than that of a given construction.

BUTLER'S DIAL LOCK, Patent dated August 13th, 1855.

This invention consists in affixing a number of stumps to the bolt of a lock, which stumps bear against circular pieces of metal revolving on centers connected with the upper plate of the lock; these circular pieces form stops against which the stumps bear. In the revolving stops are found grooves, through which the stumps pass when the bolt is shot in or out. Thus it will be seen that the bolt cannot be moved until each of the stops is arranged with its groove opposite to the stump on the bolt which is to pass through it.

The stops may be turned by hand from the exterior of the lock, but the patentee prefers so to arrange them that they can only be turned by a key introduced through keyholes arranged round the main keyhole on the face of the lock. On the front plate of the lock are arranged hooks, which catch into the bolt, so that the plate of the lock can only be removed when the bolt is half shot, or in some other previously arranged position.

NEWTON'S LOCK, Patent dated November 14th, 1855.

The first part of this invention consists of a method of impressing the form of the key upon inert tumblers, which are then removed from reach or influence through the keyhole before they reach the fence, which permits them, if properly arranged, to be moved far enough to permit the bolt to be thrown, but which cheeks them if not perfectly arranged. This part of the invention also consists in restoring or bringing back the tumblers to their original relative position as they are brought back within reach of the key, so that they can in no manner indicate what key has

been used.

The invention also consists in so cutting the edges of that portion of the key-tumblers on which the key acts as to prevent the long bits of the key from marking their length upon the tumblers, and thereby avoiding all chance of taking an impression of them. And this part of the invention also consists in the employment of a wiper, to pass over the surface of the tumblers which have been acted on by the short bits of the key to remove any print or tract which might have been left by the short bits in acting upon them, and thereby avoiding all chance of taking an impression of any of the bits of the key.

FENTON'S LOCK, Patent dated January 21st, 1856.

The inventor constructs a mortise lock, in which one bolt is made to serve all the purposes of the three bolts in the ordinary mortise lock. The bolt is pressed forward by a double, or elliptical, or curved spring or springs, and is drawn back by turning a spindle with a knob at each side of the door, like the first bolt of the ordinary lock above mentioned.

The lower part of the bolt is for being acted upon by the key, so that the bolt may be shot farther, and for locking the door. The bolt is kept out by a tumbler, which drops into a notch in the bolt. The bolt has another long notch, in which the stud of the tumbler lies when the bolt is unlocked. The bolt is secured from one side of the door without using the key, by means of a piece of metal or lever, moved by a spindle and knob, and locking into a notch, or behind a projection on the bolt; thus paralyzing the bolt, and answering the same purpose as the third bolt in the ordinary lock above mentioned.

TUCKER S SAFETY LOCK, Patent dated June 13th, 1856.

In all the previously patented locks of this inventor it will have been observed that no tumblers or levers acted on by springs have been used, except in the locks under the present patent he has availed himself of the ordinary levers used by other makers, and has simply endeavored so to modify the construction as to render such locks secure against picking by pressure, without diminishing their strength or materially increasing their cost.

The manner in which such security against picking by pressure is effected in the present lock is as follows: Proceeding upon his characteristic idea, "that the reason ordinary lever locks can be

picked is, that communication with the levers can be obtained while the tumbler-stump is in contact with them," he has here introduced what he terms a "tumbler-guard," so constructed and disposed as to *stand* between the tumbler-stump and the *gating faces* of the levers when the bolt is locked out, and which tumbler-guard must first pass into the gatings of the levers before the tumbler-stump can reach them.

By this means the tumbler stump can *never be made to touch the levers until the whole of them have been correctly adjusted for its passage through their gatings.* The tumbler-guard is a horizontal plate, with a return or vertical projection rising from it; this plate runs upon guide or *lanket* pins fixed in the plate of the lock, and is in no way pivoted or attached to the bolt, and it is its vertical projection which stands between the levers and the tumbler stump, (which latter is riveted to the bolt in the ordinary; way).

The action of the guard is such, that when pressure is applied to the bolt, the vertical projection is brought against the faces of the levers, and a slot in the horizontal plate is made to fasten itself to a guide pin in the plate; its backward action being thus retarded, the tumbler-stump then reaches the horizontal plate, which is thus made to sustain the pressure of the tumbler-stump and prevent it from being brought into contact with the levers, so as to enable the gatings to be felt.

By this arrangement, and by the use of a guard to the levers, all the advantages afforded by a *loose or moveable stump* are obtained, without in any way impairing the strength and durability of the lock; on the contrary, the resistance to violence afforded by this lock is considerably greater than in an ordinary lever lock, as the pressure of the tumbler-stump against the tumbler-guard must *always* be at the *base* of the stump, *altogether irrespective of the particular levers* which may be incorrectly arranged, whereas in locks made with a loose tumbler-stump, the resistance afforded against violence is materially less than in an ordinary lever lock.

It is this specific purpose of affording security against picking by pressure without detraction from the strength of the lock which has caused the production of this lock, and such purpose is expressly specified by him in his specification. Other contrivances are specified under the same patent, but not being yet commercially introduced, no description of them can be given here.

In reviewing the various *modern locks* which we have now described, our readers will doubtless be tempted to put the question: Are there any amongst them combining the true principles upon which locks should be constructed, viz., perfect security, strength, simplicity, and durability; or possessing the qualities enumerated by Mr. Chubb in his paper before referred to, namely:

First: Perfect security is the principal point to be attended to, as without it no lock can be considered as answering the intended purposes.

Second: The works of a lock should in all cases possess strength, and be well adapted, especially in the larger ones, to resist all attempts to force them open; and both in the larger and the smaller kinds, the works should not be susceptible of injury or derangement from attempts with pick or false keys.

Third: Simplicity of action is requisite, so that any person having the key, and being unacquainted with the mechanism of the lock, should not be able to put it out of order.

Fourth: The workmanship, materials, and interior arrangement of a lock should be so combined as to insure the permanent and perfect action of all its parts, and its durability under all ordinary circumstances.

To this question we answer, **Yes**. There are some possessing all the latter qualities, whilst there are others not only combining all these excellencies, but which would successfully compete for another medal and premium if the Society of Arts were again to offer such a reward "for the invention of a good and cheap lock, combining strength and great security from fraudulent attempts; cheapness, freedom from disarrangement by dirt, and requiring only a small key."

To name them here would be invidious; but we believe our description of them cannot fail to point out those we refer to. The *real* improvements introduced into the construction of locks since 1851 are certainly not numerous, but they are effective and to the purpose; and if inventors and lock manufacturers will only keep in view the principle upon which all machines should be constructed, namely, simplicity, we do not despair of seeing at no distant time a lock possessing all the before-named qualities, and of such a simple character, that it shall be minus those

bugbears in every lock, and the most troublesome limbs to all locksmiths—viz., SPRINGS.

CHAPTER SEVENTEEN: The Lock Controversy since the Closing of the Great Exhibition

In resuming the lock controversy, we shall continue it in the same chronological order, and shall reserve our remarks on the subject generally till the close of the chapter.

After Mr. Hobbs had succeeded in picking the Chubb and Bramah locks, it was natural for the English locksmiths to desire to pick the American locks, and several attempts to pick the Parautoptic Bank Lock were accordingly made. A challenge was affixed to one of these latter locks in the Great Exhibition, offering a reward of two hundred pounds to any one who succeeded in picking it. Mr. Garbutt, an engineer, accepted the challenge, and on September 10th, 1981, Mr. A.H. Renton, Mr. E.H. Thomson, and Mr. W.F. Shuttock were appointed arbitrators to superintend the arrangements.

These gentlemen met Mr. Garbutt at the house, No. 20, Knightsbridge, when the following conditions were agreed to:

-"That a Newell lock should be selected, and should be screwed to a wooden box; that Mr. Garbutt should have access only to the keyhole of the lock, through which keyhole all his operations for picking the lock should be conducted; that Mr. Garbutt should have uninterrupted and exclusive access to the box between the hours of nine in the morning and nine in the evening, for thirty days, beginning on the 11th of September, he having during that time the privilege of introducing one associate, and the arbitrators reserving to themselves the right of inspecting the seals placed by them on the box; that in order to afford every information concerning the internal arrangement of the lock, the trial lock should be taken to pieces in the presence of all the parties; that it should be examined by Mr. Garbutt; that it should be locked and unlocked with the proper key by him and Mr. Hobbs; that it should be fastened to a box and the fastenings sealed by the arbitrators; that the key, when the lock was

finally locked, should be sealed up by the arbitrators and delivered to Mr. Hobbs, who would retain it until required by the arbitrators to hand it over to them. That at the expiration of the thirty days, or earlier in case either of the success or the abandonment of the attempt, the arbitrators should examine the lock. And, finally, that if Mr. Garbutt should have succeeded in picking the lock (that is, in withdrawing the bolt without injuring the lock), the sum of £200 should be paid to him by Mr. Hobbs."

In accordance with the above agreement, Mr. Hobbs produced a parautoptic lock with ten levers, No. 8560, which with the key were examined by Mr. Garbutt. The lock was afterwards fixed to a box and sealed. Mr. Hobbs then set the ten bits of the key, corresponding to the ten levers, to an arrangement chose by himself; the lock was then locked and unlocked by all parties in succession, and the key, after the final locking, was sealed up and give to Mr. Hobbs, who at the same time delivered to Mr. Garbutt a similar but smaller lock, which he was to be allowed to retain during the whole period of the trial. This was intended to make him familiar with the construction of the lock to be operated upon.

The prescribed period having expired on the 11th of October, the arbitrators met at the before-mentioned house, when Mr. Garbutt delivered up to them the lock in its locked condition and perfectly uninjured. The arbitrators then gave the following award:

-"We therefore hereby certify that Mr. Garbutt, having had uninterrupted and exclusive access to the lock during the period of thirty days, and availing himself of the conditions of the agreement, had every facility for opening the lock that could be obtained without possession of the true key, has delivered up the same into our hands unopened and uninjured; and the said lock has been delivered by us to Mr. Hobbs."

This brings us to the year 1852, when another attempt was made to pick the parautoptic lock. The following account of it is taken from the Observer of that period: -

'Hobbs' American Lock Again

"It will be remembered that, in The Observer of the 28th of March, a challenge appeared from Jeremiah Smith, offering to pick Hobbs' celebrated lock, an opportunity of attempting which he

complained had not been afforded him at the Great Exhibition. On the 11th of April we published a reply from Mr. Hobbs, in which he expressed his readiness to afford Mr. Smith every facility for making the attempt, and appointed a certain hour at his warehouse in Cheapside, on the 14th of April, to make the necessary arrangements. Mr. Hobbs proposed the appointment of three arbitrators to decide the time, place, and terms for the trial to be made, and named, as two of them, Mr. Hensman, engineer to the Bank of England, and Mr. J. G. Apphold, of Finsbury Square, requesting Mr. Smith, the challenger, to name a third party to be present and to act with them. Mr. Smith attended the meeting, but brought no friend with him to act as the third arbitrator, stating that he did not understand from the terms of the challenge that he was to bring anybody.

The Exhibition Lock, which excited so much wonder and admiration at the Crystal Palace, was then produced, and in the presence of Messrs. Hensman and Apphold, Mr. Smith was asked if he would undertake to pick the lock? He replied in the affirmative, but would prefer having one that was fixed upon a door in the ordinary way. It was observed that these were not the terms of the challenge, and it was shown further that this was impossible, as there were only one or two public offices in which the locks had yet been fixed, and that there would be both inconvenience and objection in such a course. The Exhibition Lock is one of the largest size, and contains no less than fifteen bits, or tumblers, being susceptible of we cannot venture to say how many thousands of millions of changes, and is altogether so formidable and complicated-looking a piece of mechanism, that we are not much surprised at the challenger, on a little reflection, hesitating about undertaking the task.

He observed that he did not want to attempt a test lock, which had been produced for the purposes of the Exhibition, but would have no objection to undertake an ordinary commercial lock, and Mr. Hobbs accordingly produced one of the Commercial Bank locks, containing ten tumblers, stating that although the terms of the challenge were that a sum of £200 would be paid to any person would pick the “Exhibition Lock,” he would substitute the smaller and less complicated one, to meet Mr. Smith’s views, and put the matter out of dispute. It being found very difficult to bring Mr. Smith to any decisive terms, a suggestion was made for a subsequent meeting, when Mr. Smith was to come prepared with a friend to enter into the necessary arrangements.

On Tuesday last, a friend of Mr. Hobbs called upon Mr. Smith

appointing the following day (Wednesday), at three o'clock, at the offices in Cheapside, and Mr. Smith undertook to be there with a friend. Mr. Hobbs was in attendance with the two arbitrators, Messrs. Hensman and Apphold, and remained in waiting from three till a quarter past four o'clock, but Mr. Smith did not appear, nor any friend on his behalf, nor was any letter or message sent to explain the cause of his absence.

Under all the circumstances we cannot come to any other conclusion than that Mr. Smith has thought better of his challenge, and has, by withdrawing form the ordeal, given a tacit admission of the invulnerability of the American lock. As The Observer was the means in the first instance of giving circulation to the report that one of these locks had been picked, which, on subsequent inquiry, turned out not to be the case, the feat having been achieved by making a facsimile key from the original, and going through the 720 permutations of a six-bit lock til the right combination was hit upon, we have thought it but fair to Mr. Hobbs to give this narrative of the circumstances connected with Mr. Smith's rather confident challenge and its inconclusive termination.

Mr. Hobbs has, in every instance in which any person came forward to attempt to pick his lock, acted with the greatest fairness and liberality, and has at the present moment no less than seven of his locks in the hands of adventurous experimenters who wish to make themselves acquainted with the principle before attempting a task the successful accomplishment of which would be attended with so much glory and so much pecuniary advantage. The lock, however, has up the present time remained invulnerable; and although we do not hesitate to say that we should feel extremely proud if any ingenious mechanic of this country could be found to turn Brother Jonathan's flank and establish our mechanical and scientific superiority in this particular, we are bound to say that hitherto the American lock has maintained the reputation its proprietors claim for it as one of the most perfect combinations for security yet invented."

About this time Mr. Hobbs read a paper before the Society of Arts on locks and keys, when a discussion arose, in which it was stated that the parautoptic lock had been picked in London, the truth of which statement Mr. Hobbs thought it was his duty to deny. It appears the report was published in the Observer, and many of the other London journals, which called forth from Mr. Hobbs a letter, dated April 2nd, 1852, addressed to the editor of the above paper, and containing the following paragraph:

–"Early last autumn I lent to Mr. Potter, of South Molton Street, one of my locks, for the purpose of giving him an opportunity to make himself acquainted with its principle and construction. After he had had the lock in his possession several weeks, a report reached me that one of Mr. Potter's workmen had picked my lock. I immediately called on Mr. Potter to ascertain the fact. Mr. Potter informed me that for the purpose of testing the possibility of opening the lock by means of an impression taken, or a copy being made of the true key, Mr. Smith had made a copy of the key by means of a transfer instrument, which instrument he showed me at the time. After the key was made, it was tried, and found to lock and unlock the locks as readily as the original key. Mr. Potter then sealed the screws of the lock, and with the key that he had made by copying the original, hit the combination and unlocked it. The lock was of the smallest size, having but six levers; the number of changes that could possibly be made were 720. The time occupied by Mr. Smith, according to his own statement, was six hours and fifty-five minutes; this, allowing one minute for each change, would give him time to have made 415 out of the 720 changes before hitting the right one. I asked Mr. Smith why he did not use the original key instead of making a copy? His answer was, that 'he could change the one he made faster, as he did not have to screw the bits in.' Any person will readily understand the difference between **ringing the combination(536)** of a key and picking a lock.."

This lock was evidently opened by ringing the changes; but this was certainly not picking it. We have before alluded to the difference between picking a lock by instruments and opening it by ringing the changes with a permutating key, and we shall further explain and illustrate this important difference in the chapter on keys.

We now come to the unfortunate affair of the Society of Arts in connection with this subject. It had been customary with the Society from its first establishment to offer premiums for various inventions, and not unfrequently for a lock, and on the 1st of November, 1852, the Society offered a premium "For the invention of a good and cheap lock, combining strength and great security from fraudulent attempts; cheapness, freedom from disarrangement by dirt, and requiring only a small key."

Various locks were sent to the Society for competition for the premium, and the committee, of which Mr. Chubb was the chairman, gave their award in favour of the lock invented and exhibited by

Mr. Saxby, who received the Society's medal and a bounty of ten guineas. This lock (which from the description of it, contained nothing new either in principle or construction) Mr. Hobbs picked "in the presence of parties connected with the Society, in the short space of three minutes."

This circumstances led to much newspaper correspondence, and the committee were so much censured for their want of discrimination and judgment in choosing that lock which was so soon and so easily proved not to possess any qualities justly entitling its fabricator to the honour of receiving the Society's medal and the premium of ten guineas.

The question raised by the Society's award will be best understood from the following letters before referred to. The first was from Mr. Hobbs, and appeared in the Journal of the Society of Arts, June 25th, 1853, and is as follows:-

"Sir, – As the recognition of merit, and the encouragement of improved manufactures and inventions by a body like the Society of Arts is a matter which ought to be as far removed from suspicion of any gross error as the fallibility of human judgment will admit, it will not be considered intrusive, perhaps, if I submit the following cases to your judgment:--

"On the 1st of November, 1852, the Society issued their usual circular containing an offer of premiums for various articles, and amongst others (No. 83), 'For the invention of a good and cheap lock, combining strength and great security from fraudulent attempts; cheapness, freedom from disarrangement by dirt, and requiring only a small key.'

"Being engaged in the manufacture of locks I considered the subject with some attention, but perceiving that the conditions were not perfectly consistent with each other, I gave up all hopes of obtaining the prize, and looked forward with more curiosity than anxiety for the new productions of lockmaking ingenuity that might be called forth by the liberal offer of the Society of Arts. At length your journal of the 11th instant informed me that the medal of the Society, and a premium of £10 had been awarded to Mr. Saxby, of Sheerness, for a lock that answered all the requisitions.

On calling at the society's rooms to inspect this piece of mechanism, I was surprised to discover that it was constructed

precisely the same principle as the 'Yale Lock,' described in a paper read before the society in January, 1852, and of the same construction as locks manufactured and sold by Mr. Cotterill, of Birmingham; in short, that it had no claim whatsoever to be regarded as a new invention by the committee of the Society, however honestly it might have been submitted as one by the maker. The want originality in the lock, supposing that it answered all the conditions named in the circular, might have been passed over as a venial offense. This unhappily was not the case. That the essential requisite of security –'great security,' as it is expressed in the circular, did not belong to it, was proved by a very simple experiment. To be brief, I picked this prize lock in the presence of parties connected with the Society, in the short space of three minutes!

"I do not mean to insinuate that there is any general carelessness in the selection of parties to determine the merits of competitors, or in their competency to form an opinion upon the worth and utility of the articles submitted to them. It is simply with the committee on locks, and with this particular case, that I have to deal; and it must be self-evident from the above statement tat they have betrayed their incapacity in the most flagrant manner. The case is still more surprising when I observe that Mr. Chubb, of St. Paul's Churchyard, was a member of the committee by which this award was made. This singular fact exonerates the Society indeed from which a gentleman of Mr. Chubb's repute, as a mechanic in that particular branch of art, was a member, should be implicitly trusted.

"Respectfully yours,

"A. C. HOBBS.
"79, Cheapside, June 21st, 1983"

The above letter attracted the notice of the editor of the Bank's Circular, in which the following notice appeared on July 2nd, and was copied into the Times of the 7th;--

"Mr. Hobbs and the English Locksmiths.

"It is now pretty generally known that until the year of the Great Exhibition nobody had succeeded in obtaining the '200 guineas' offered by Messrs. Bramah to any person who could pick their celebrated lock. This piece of mechanical ingenuity was at last performed by Mr. Hobbs, from America, who was not a

lockmaker, but a lockpicker. Since then the art of picking locks has become somewhat elevated, and has attracted the attention of several of our first-rate engineers.

"The Society of Arts in John Street, Adelphi, desirous of promoting the skill of English locksmiths, issued a circular last year for premiums on various articles of manufacture, amongst which was one 'for the invention of a good lock, combining strength and great security from fraudulent attempts, cheapness, freedom from disarrangement by dirt, and requiring only a small key.'

"The condition upon which the prize of £10 was to be awarded seemed to be somewhat inconsistent with the object required; but nevertheless the offer commanded attention, and the successful competitor was Mr. Saxby, of Sheerness; and to him the prize was awarded by the committee, the chairman being Mr. Chubb, the lockmaker in St. Paul's Churchyard.

"By a letter from Mr. Hobbs, which appeared in the Journal of the Society of Arts of the 24th of June, we find that Mr. Hobbs' curiosity, which was only equaled by his modestly in not competing for the prize, induced him to inspect this piece of mechanism which the committee, presided over by Mr. Chubb, had pronounced to be the one most in accordance with the prescribed rules of the society; when, so far from its possessing that 'great security' required, he discovered that it ws constructed on the principle of the 'Yale lock,' such as are manufactured by Mr. Cotterill, of Birmingham; and to prove to the parties present that is possessed no 'security,' Mr. Hobbs, taking a small straight iron wire from his pocket, and a thin strip of steel, opened it in the presence of several members of the society in three minutes!

"Without offering anything of a personal insult to Mr. Chubb, it is impossible not to question the accuracy of his judgment on this branch of mechanical art. There can be no doubt that the first requisite in a lock is perfect security; but if the public are misled by the mistaken judgment of men who decide upon the merits of the question, it will undoubtedly throw great suspicion upon the character of public scientific institutions."

The above remarks as well as the following are worthy of special notice, as coming from independent commentators on the question involved in this controversy.

"Love (Hobbs?) laughs at locksmiths."

"In the month of November last the Society of Arts, in its praise-worthy efforts to promote mechanical and scientific ingenuity in this country, issued their usual circular, offering premiums for inventions and improvements in various departments of industry; and among the rest, one for the invention of a good and cheap lock, combining strength and great security from fraudulent attempts, cheapness, freedom from disarrangement by dirt, and requiring only a small key. Now this was, no doubt, a great desideratum; but the amount of mechanical ingenuity, and the quantity of skilled mechanical labor, which were requisite to produce a lock combining great strength and security from fraudulent attempts, were evidently inconsistent with the element of cheapness, which was also stipulated for by the society.

If appears, however, that the stimulus of honorary distinction and pecuniary reward, induced several of our mechanicians to compete; and a lock was produced by MR. Saxby, of Sheerness, which, it was alleged, answered all of the requirements of the circular. A committee was appointed to investigate the merits of the various inventions, and Mr. Chubb, of St. Paul's Churchyard, the eminent lock manufacturer, was appointed the chairman, and a report was drawn up, in which, for the reasons therein alleged, the Society's medal and a sum of £10 was awarded to Mr. Saxby for his invention. We have not had an opportunity of seeing the report, but we must presume that the committee were satisfied that the conditions of the Society's circular were complied with, otherwise, the conferring the honorary and pecuniary rewards was a mere farce, and by no means calculated to raise the character of the Society of Arts in the estimation of the public.

"It turns out, however, that the lock submitted by Mr. Saxby has no claim whatever to originality; it is constructed on precisely the same principle as the 'Yale lock,; which was described in a paper before the same society so lately as January, 1852. It is also the same in character and principle as the locks manufactured and sold by Mr. Cotterill, of Birmingham, without their security or complication. It can scarcely be supposed that a scientific body like the Society of Arts could have been ignorant of these facts; and even if they were, we cannot understand how they could have escaped the penetration and judgment of the chairman, himself a practical mechanician. We acquit Mr. Saxby of all complicity in the affair; he may have honestly and ignorantly believed that his lock was an original invention, or such an improvement and simplification of the model

as entitled him to the reward; the committee may likewise have made their adjudication in good faith, but it is certainly calculated to lessen the pubic confidence in the decisions or recommendations of the society, when we find that besides the total absence of originality, the other and more important element of security is entirely wanting.

"It appears that as soon as the announcement of the award was made public, Mr. A. C. Hobbs, the patentee of the celebrated American Lock, who obtained no inconsiderable amount of celebrity, such as it was, during the Great Exhibition, by picking the patent locks of some of the most eminent firms, and who had so little hope himself of being able to meet the contradictory requirements of the Society's circular, that he had abstained from entering the lists as a candidate, went to the Society of Arts on the 16th instant, for the purpose of examining the prize lock.

After some little difficulty of delicacy, arising probably from the unwillingness of the parties to put him out of countenance, the lock was produced and Mr. Hobbs, taking out of his picket a thin slip of steel, and a straight iron wire, picked the lock in the presence of some members of the society in three minutes! The lock was then examined by Mr. Hobbs, and found to be an exact copy of Cotterill's Birmingham lock, but of course much more indifferently constructed.

The principle of the lock, it may be stated, is the same as the patent Bramah lock, with this difference in its application: the slides in the Bramah lock are pressed onto the barrel parallel with the motion of the key, while in 'the prize lock' of Mr. Saxby, and in the Cotterill lock, the motion of the slides is from the centre to the circumference of a disc.

With instruments properly constructed, Mr. Hobbs says, 'the prize lock' might e picked in less than a minute, and we have been given to understand that it does not meet the conditions of the Society's circular, either as regards originality, cheapness, security, or non-liability to derangement from dirt. There is certainly in this statement of facts, which we believe will be found substantially correct, evident proofs of incapacity, carelessness, or favoritism on the part of the committee of the Society. The Society were, doubtless, fully justified in placing confidence in a committee so constituted, and the latter will probably be able to explain how they arrived at a decision which speaks little for their mechanical acquirements, or for their

investigation of the merits of the article submitted to them. They may be certain of this, that the indiscriminate distribution of the honours and rewards of the Society is not calculated either to stimulate the inventive genius of our artisans or to elevate their own character in public estimation."

The following anonymous[1(537)] reply to the letter of Mr. Hobbs appeared in the succeeding number of the Journal of the Society of Arts, namely, July 1st:--

"Sir, –I observe in last week's Journal a letter from Mr. Hobbs on the subject of Mr. Saxby's lock, recently rewarded by the Society, which I think needs a few words of explanation and reply, as your acute correspondent appears to be somewhat in error as to the circumstances of the case.

"The remarks of Mr. Hobbs appear to amount to this; first, that Saxby's lock is not new, the principle being the same as the Yale lock, and as Cotterill's lock; secondly, that it is not very secure, because he picked it.

"Now, unquestionably, Saxby's lock is constructed on the same general principle as Cotterill's and Yale's, and both of them in turn are derived from the Bramah; but this does not prove the locks to be the same; an did Saxby, by ever so slight a modification, produced a lock for half-a-crown as good as Cotterill's lock for ten shillings, then Saxby certainly deserved the Society's prize.

"In seeking for a 'cheap and very secure lock,' it is evident that the Society desired a good common lock, one which could be made and sold for a few shillings, and yet be much more secure than the locks commonly to be had for such a price, which in fact are too often no locks at all, being easily opened and locked again with a bit of wire or a bent nail.

"The term 'great security,' as set forth in the prize list, mean, I imagine, great security against the attempts of the idle and mischievous; but it certainly never aspired to defy the systematic ingenuity of a professional lock-picker like Mr. Hobbs. The great security of the storeroom or apple loft is not to be compared with that of the banker's safe or deed box; and a lock intended for the former, and perfectly secure against all trials to which it might be put, would no doubt be set aside as valueless for the latter.

"I think that no one expected, as the result of the Society's premium, an unpickable banker's safe lock for five shillings.

"Whether Mr. Saxby's lock is quite new in principle, or whether it is in fact merely a modification of some older lock, is not the question; neither is it important to inquire in how many minutes Mr. Hobbs picked the lock. The real point is, that Saxby's lock is much more secure than common locks are, and that it costs much less than really good locks commonly do.

"I am, Sir, yours faithfully,
"P.L.O."

Mr. Hobbs replied as follows, (Journal of the Society of Arts, July the 8th):--

"Faith! Here's an equivocator!" –Shaekspeares

"Sir, –Had your correspondent, P.L.., really afforded the 'explanation and reply' promised in his opening paragraph, I should hardly have troubled you with a rejoinder to his observations. Either I am not so 'acute' as his flattering designation would lead me to suppose, or his 'explanation' must be deficient in point and clearness; for I can neither see that it justifies the committee on locks, by whom the premium was awarded to Mr. Saxby, or that it corrects my opinion concerning the requisitions of the Society.

"Not to occupy your space unnecessarily, I will simply repeat the words of the proposal made by the Society, and submit my own understanding of them for comparison with the judgment of P.L.O. The offer was made for 'the invention of a good and cheap lock, combining strength and great security from fraudulent attempts; cheapness, freedom from derangement by dirt, and requiring only a small key.' I supposed the above to mean that a lock was to be produced either on a new principle or by the arrangement of some principle already known, which should combine, with as much strength as any lock now in the use, as great or greater security, and yet be capable of manufacture at a lower price for the various purposes of which locks are required, and should require only a small key.

If I am not mistaken in the plain import of the language, I may venture to repeat that the lock for which the committee have awarded the premium of the Society does not in the most distant

manner come up to the requisitions. Instead of its being either a new principle or a new arrangement, it is precisely the same both in principle and arrangement as the Cotterill lock, without the slightest modification; in fact, only differing from it in the inferiority of its workmanship. It is less secure than either a Bramah or tumbler lock of the same cost, and is quite liable to be deranged by dirt. It requires a key of the same size as the Bramah and other locks.

"I make no comment upon the wisdom of supposing that the Society intended to award a premium for the means of securing P.L.O.'s 'apple loft' from the pilfering propensities of his naughty boys; the words are for great security from fraudulent attempts, and they need no commentary to make them plainer.

"In conclusion, it would give me great pleasure to be afforded an opportunity of proving the correctness of my statement to the Society by a comparison of the different kinds of locks now in use. I am prepared to prove also that as good a lock cannot be produced by Mr. Saxby for half-a-crown as by Mr. Cotterill for ten shillings. In regard to 'professional lock-picking,' I will undertake to show that Mr. Saxby's lock can be easily opened and locked again, not by the application of extraordinary skill or anything so profound as 'systematic ingenuity, but by a bent nail and a bit of wire, or by a key made of a piece of pine woods; in a word, that the principle of Mr. Saxby's lock is neither secure for the 'storeroom, the apple loft, nor the banker's safe;' that it is not 'much more secure than common locks;' and that it cannot be produced at a lower price than 'really good locks.' This proposition being distinctly understood, your correspondent P.L.O. will have some difficulty in satisfying either the Society of Arts or the public that the committee on locks have not committed a very ridiculous blunder.

"Respectfully yours,
"A. C. HOBBS.
"97, Cheapside, July 5th, 19853."

In the same number were also the following letters from other correspondents:--

"Tiverton, July 2nd, 1853.

"Sir,-I should be sorry unnecessarily to trespass upon your

columns; but the fact of the lock of Mr. Saxby, for which the medal was awarded by the Council of our Society, having been proved by the successful experiment of Mr. Hobbs to be even ludicrously unsafe, renders it imperative on me, having been a competitor with Mr. Saxby for the prize, to take this public means of disabusing the minds of the many persons at present cognisant of, or who may hereafter be acquainted with, the fact of my having so competed, of an opinion they must naturally form from the premises: –That the lock considered by the committee to be the most deserving of the prize having been shown to be utterly untrustworthy, mine consequently was in all likelihood equally, or supposing such a circumstance possible, still more insecure. That such is not the case, and that in this instance the committee have in their desire to introduce a cheap lock attached too little importance to the still more requisite element of perfect security, I will (in order to vindicate the reputation of my lock from the stigma which must otherwise, in consequence of this error on the part of the committee, rest upon it) venture to demonstrate in a manner at once conclusive and unquestionable, and which, under the present circumstances, cannot I think be considered objectionable.

I submitted it to the decision and criticism of the Society in the full confidence, not only that it would prove to be a 'cheap lock,' but that it was not possible, by any amount of skill or perseverance, to succeed in picking it. In such belief I still continue; and in order to convince my friends and the public that the decision in Mr. Saxby's favour was not owing to any want of security in mine, I herewith publish my intention of placing the sum of £100 in the hands of a banker, to be handed by him over to Mr. Hobbs, should be succeed within the next three months in picking the patented lock of my construction, which was placed before your Society in competition for the prize.

On receiving notice from Mr. Hobbs, through your journal, of his intention to make the attempt, I will at once commence fixing it in a manner suitable for experiment; on the completion of which, he shall be at liberty to examine a lock constructed on the same principle, that he may acquaint himself with its peculiarities, after which I will allow him ten days in which to effect his purpose; conditioning solely, that either myself or some person appointed by me, shall, if I shall so require it, be present during the operations to prevent violence or injury to the lock. No other sufficient means being open to me but the present of removing whatever prejudice may have been created against my invention, by the erroneous decision of the lock committee, must

be my excuse for thus occupying your space.

"I am, Sir, yours respectfully,

"W.H. TUCKER."

"Sir,–I have never seen a more unfortunate attempt at getting out of a scrape, than the anonymous letter in the Journal last week written almost avowedly by some member of that sagacious committee which gave a medal and something more to the inventor of a lock, which Mr. Hobbs has shown to possess the two qualities of antiquity and good-for-nothingness in an eminent degree.

"They now pretend, at least their advocate does for them, that they understood–nay, that 'it is evident that what the Society desired was a good common lock.' If so, do they think the Society could not have said so? If so, why did the Society say something as different as possible? If it is so evident, why does P.L.O. take so much pains to explain that the expression 'great security' in the premium list just be understood to mean only as great security as you can expect for half-a-crown? The prize list said nothing about half-a-crown, and did specify 'great strength and security from fraudulent attempts,' and also from 'disarrangement by dirt,' and that the lock was only to require a small key.

"To anybody but Mr. Chubb and his committee this rather particular description must have suggested anything rather than a cheap common lock; but it did not to them–at least so they assure us now. The fraudulent attempts, we are told, could not be supposed to have any reference to bankers' safes, because you cannot expect a good bank lock for the price of a good common lock; and a common lock, we know, is the thing the Society meant to ask for. And therefore it is evident that the fraudulent attempts the Society had in view were the attempts of the 'idle and mischievous' on the 'storeroom or apple loft.'

"The freedom from 'disarrangement by dirt' required by the Society's conditions could not possibly suggest to the intelligent minds of Mr. Chubb's committee the idea of one of Mr. Chubb's locks having to be broken open on account of two of the tumblers having got stuck together, Mr. Chubb, of course, never heard of such a thing. The expression, no doubt, suggested to them only the idea of a mischievous boy stuffing dirt into the lock of the aforesaid storeroom or apple loft, by way of paying

off the owner for being so ill-natured as not to leave it open.

"'No one expected, as the result of the Society's premium, they say, 'an unpickable bank lock for five shillings.' Probably not: but there is a widish margin left between an unpickable bank lock for five shillings, and Mr. Chubb's pickable one for five pounds or thereabouts. If the committee had no lock presented to them, which (as far as they could judge) did 'possess great strength and security from fraudulent attempts, freedom from disarrangement by dirt, requiring only a small (that is, of course, alight) key, and cheap, for a lock possessing those qualities, which is the only rational meaning of the word, they had nothing to do but so to report to the Council. Or, if Mr. Chubb's committee did not chose to give any encouragement to a lock which might be likely to interfere with Mr. Chubb's locks, they might have given no premium at all with at least as much credit to themselves as they have obtained by what they have done. Or, if they really meant to reward Mr. Saxby for cheapening the construction of an old lock, they might have done so, taking care to inform the public what their reward was for.

"They did none of these things, but committed the gross blunder so properly and promptly exposed by Mr. Hobbs. And they now add to it the much grosser and more discreditable blunder of attempting to disguise it, by an excuse which everybody can see is a pure ex post facto invention from beginning to end. I think it due to the credit of the Society to expose such a proceeding as it deserves. If P.L.O. had put his name to his defence of himself and his colleagues, he should have had mine to this answer to it. As he has not, I take leave to subscribe myself,

O.P.Q."

"Sir, -On perusing in the Society's Journal a letter from Mr. Hobbs, who has obtained notoriety for his mechanical skill in opening or picking locks, manufactured by those who have hitherto been allowed to occupy the highest position in that branch of mechanism, I beg to state that I was not aware (until I saw the above) that a premium had been offered for a good and cheap lock, or I should have been a competitor or the honour.

"I have invented and patented a lock, which I do not hesitate to say is the strongest, the simplest, and yet the most secure, and least liable to become injured by dirt, &c., of any others ever made. It is sold for 5s. and less; and although so low in price, I have no objection to Mr. Hobbs trying his

professional skill upon it, using as many instruments, and of whatever kind he may please to select.

"That gentleman is quite aware of having been invited on more than one occasion to try his skill upon the 'English Protector Lock.' He is conscious that it is exceedingly simple in its arrangement, having no detectors, no catch under the bolt, or loose stump as in his own, or any obstruction of the usual kind as a preventive to the bolt's passage. Standing alone, it possesses an original simple principle, distinct from all other locks. Unlike all other cheap locks, I guarantee, this to be as secure as the most expensive. I cannot agree with your correspondent, P.L.O., that a lock, which in a few minutes may be picked, can be by any arrangement proved to possess great security; for the object of any lock, however, moderate its price, and of any improvement in one, must, when practically and commercially considered, be to produce this result, namely, equal security, although at a diminished cost.

"The originality of the principle upon which the English protector lock is contrived consists in it being impossible to fix up the tumblers in succession as in other locks; for, after raising one tumbler, the attempt to do so with a second necessitates the fall of the first. A portion of the bolt is always jutting against a steel cylinder working in the top and bottom of the lock. This cylinder is so placed that it is impossible to move the key, or any instrument inside the lock, without at the same time giving motion to it; and in any attempt to pick the lock, this cylinder will always prevent the bolt being pressed against the tumblers, thereby destroying the power of fix them in any particular position.

It is only when the tumblers are all raised by the key to their exact position that the portion of the bolt described above can advance, and upon doing so, it passes under the key and enters the cylinder, filling an opening in it. It will therefore be readily understood that, supposing a false instrument be introduced, the tumblers will not be raised to their required situation; and although one may be fixed, a second cannot be; for, immediately the attempt is made to remove the instrument in use, for the purpose of introducing others; motion is given to the cylinder, and necessarily the bolt, immediately causing the fixed tumbler to return to its original position. It is only an instrument exactly like the key which will produce any effect, and of course one like the key would be the key, therefore not picking the lock.

"The above lock is made in unlimited quantities, without having any two locks the keys of which would suit each other.

"Excuse my remarking, in conclusion, it is not single unpickable locks which manufacturers of locks care about, although they may be very interesting mechanical curiosities. It is to have an exceedingly simple and yet never-failing preventive to any one who endeavours to pick a lock, being able to ascertain the required position of the tumblers to effect this object. This preventive should be of one uniform shape or configuration, so as to dispense with mental labour on the part of the workmen, and thus enable quantities to be made at a price. The variation of each lock should consist solely in the tumblers, or in the depth of the notches in the key.

"I am prepared to show, whatever it may be required, that no lock has yet been brought into manufacture by Mr. Hobbs, or anyone else, which will equal the English protector lock in bearing an enormous amount of pressure upon the bolt.

"After stating these advantages, I trust I may be acquitted of egotism in believing this lock fulfills every condition required by the Society; viz., uncommon strength and freedom from disarrangement by dirt, and at no risk of its security. It is sold at a price which challenges comparison with any unpickable lock of the day.

"I am, Sir, yours respectfully,

"THOMAS RESTELL."

To the previous letters Mr. Saxby replied as follows:--

"Sheerness, July 9th, 1983.

"Sir, –The question of the propriety of awarding the prize to me for the lock is one which belongs, of course, to the Society, and not to the inventor. I should, however, feel greatly obliged if you will make the following explanation public:--

"The committee were satisfied that the idea was original to me, and I care not to disabuse the minds of other persons who may believe the poor mechanic to be guilty of piracy. As a general

rule, it is not such as we who live on the wits of our fellows.

"The only part of Mr. Hobbs' first letter on which I think an explanation is due is that which refers to the insecurity of my lock against fraudulent attempts. Now, Sir, I must plead as my defense that I did not conceive the idea until about a fortnight before the specimen was due, and could not apply myself for more than half-an-hour at a time to is manufacture; and not being a locksmith, I had the rudest tools imaginable. The consequence was that the specimen illustrated the principle, but did not defy the ingenuity of Mr. Hobbs, who had previously examined it, and discovered that neither the notches nor the rim were accurately made, either in form or corresponding dimensions. Had they been so, he would have had much more difficulty in succeeding.

"Allow me to suggest that the comparison Mr. Hobbs is so desirous to make for the information of the committee might be of some advantage to himself. If Mr. Hobbs has ever seen Cotterill's lock (and I believe he has), he must be aware that the statement made in the Journal of June 24th is altogether untrue, viz., 'that my lock is precisely the same, both in principle and arrangement, as Mr. Cotterill's, without the slightest modification, in fact only differing from it in the inferiority of its workmanship.' All this is untrue; and if no member of the committee requires to be enlightened by the comparison, Mr. Hobbs probably may.

"It would have sounded somewhat strange if Mr. Hobbs had stated this one fact in connection with the above, that when Mr. Cotterill made him a very liberal offer if he would pick one of his locks he declined, thinking it wiser to wait a little.

"It is scarcely necessary to remind the public that Mr. Hobbs is not the only individual capable of estimating the quality of lock; nor O.P.Q., who has at least made one discovery, viz., 'that of course a small key is always a light one;' nor Mr. Tucker, who has got £100 more than I have to spend in convincing the public that his lock and not mine should have got the prize.

"Other men equally competent to form an estimate of it have assured me that of 100 persons who could easily pick a common lock, 99 would fail in picking mine were the parts accurately fitted, which might readily be done with the necessary machinery at a low price. Hence there is an advantage over common locks of 99 per cent, in point of security.

"I am, Sir, your obedient Servant,

"H.G. SAXBY."

The following is from the Circular of Bankers, of July 9th:---

"The Society of Arts and their Prize Lock."

"We have received a copy of the Journal of the Society of Arts, containing a reply to Mr. Hobbs's letter respecting Mr. Saxby's lock, by an anonymous correspondent, which has not at all altered the views we expressed on this subject last week. In fact the vindication set forth by the writer is almost too ridiculous to notice, were it not that the subject is connected with the management of one of our oldest scientific institutions.

"The writer defines the term 'great security' by saying that it means 'great security against the attempts of the idle and the mischievous.' But if the funds of the Society are to be appropriated to be the advancement of science, surely they ought to have a higher aim than to award a prize for a lock that is only secure 'against the idle and mischievous.' We require as 'great security' in a lock for the cash box that we carry in our hand, as for the strong room where we deposit money and securities, as far as ingenuity in construction is concerned. And there can be very little skill required in picking locks for which the Society of Arts has awarded the prize, if by a simple piece of steel Mr. Hobbs could effect it in a few minutes.

"Mr. Hobbs has proved very clearly that most of the locks made in this country can be easily picked; and there can be no 'great security' in a lock until we are certain that it cannot be picked, even by the ingenuity of a Hobbs."

The contents of previous letters brought Mr. Cotterill into the field. The Times of July 13th contained the following letter:--

"COTTERILL v. HOBBS."

"To the Editor of the Times.

"Sir, –I perceive in your column of Thursday last a

paragraph from the Banker's Circular, which, if allowed to pass unnoticed, might, in the minds of those unacquainted with the merits of my lock, disparage the eminent position it has reached, and now legitimately confirmed by the united testimony of the highest scientific authorities in the realm, who, after severely testing the security of my invention, have generously allowed me to publish their unanimous opinion as to its perfect inviolability; among the goodly number I have the honor to name Mr. Robert Stephenson, M.P., Mr. Richard Roberts, of Manchester, and many of the leading members of the Institution of Mechanical Engineers. I am also proud to state that the leading mechanical journals have deemed it of such importance to the public as to give many illustrated articles on the principle of my lock, in order to prove its security. With such an array of strength on my side, it is not to be supposed that I shall shrink from meeting manfully any and every insinuation made which has for its object the lowering of my invention. Now for the paragraph in question:--

"'It appears that the Society of Arts issued a circular last year for premiums on various articles of manufacture, among which was one for a good and cheap lock. The prize was £10, and the successful competitor was a Mr. Saxby, of Sheerness, by trade a blacksmith.

"This lock (a six-inch rim) I am informed by the constructor himself could be sold at 2s. each. This cheap lock excited the curiosity of the trade, and foremost was Mr. Hobbs, who, after examining the lock at his leisure, and as often as he thought to his interest, found something in the construction resembling my patent lock, probably about as much as a wooden Dutch clock resembles a best-made chronometer; for observe, even by the aid of machinery in manufacturing, I cannot afford to sell my patent six-inch rim locks for less than 30s. each, net. From this fact alone I might leave the public to judge how far this 2s. lock resembles my patent one in those essentials which constitutes its preeminence, and which renders it the only commercial lock extant.

"I must also leave the friends of honest truthfulness to form their own estimate of a man who, in the face of such authority as the names I have quoted, could give to the public the following observations, viz.:--

"'But, so far from this lock (Mr. Saxby's) possessing that great security required, he (Mr. Hobbs) discovered that it was

merely constructed on the principle of the Yale lock (a name I never applied to any of my locks), such as are manufactured by Mr. Cotterill, of Birmingham, and to prove that the principle possessed no security he would pick this said lock.

"This 2s. lock, the picking of which he accomplished, according to the report, in three minutes, having had previously many opportunities of examining the key and the interior of the lock, and taking impressions and also measurements if he felt so disposed, picking this cheap lock under such circumstances I consider about as miraculous as his tinkering about sixteen days with a basketful of instruments, in attempting to pick Bramah's lock. I say attempting, because I believe, judging from newspaper reports, which have not yet been disproved, that Bramah's lock was not honestly picked.

Any common observer would suppose, from the eager manner in which the press gives publicity to every little movement of Mr. Hobbs, that no man in England could pick a lock; but in this I differ, being able to produce at any moment several poor working locksmiths, capable of picking any lock in half the time Mr. Hobbs occupies, and withal, consider they have done nothing worth fussing about. In reference to the remarks applied to Mr. Chubb in this matter, I have no doubt but this gentleman's long experience and well-earned reputation as a lockmaker will enable him to meet the aspersion cast upon his judgment, and give a different complexion to the whole affair.

"I shall, now for the second time, put Mr. Hobbs' ability to pick a lock upon my patented principle and my manufacture to the test, by the following challenge:--

"I will fix one of my commercial locks to a door and allow him one entire day to operate upon it, and should he succeed in picking it, I will reward him with 50 guineas. After this is disposed of, I will take him upon higher ground-viz., I will fix one of my best locks (not a Manchester machine like his) upon an iron door, and at the same time deposit 200 guineas in the hands of any respectable person, and should he be successful in violating this lock, taking a reasonable time to perform his take, he shall at once claim and receive the said 200 guineas; and in order to show that I mean business, I will pay his expenses to Birmingham; or, if he prefers it, I will bring the locks to London.

"My attention has only just been called to the paragraph in

question, otherwise this reply would have appeared earlier.

"I am, Sir, respectfully yours,

"EDWIN COTTERILL.

"105, New Street, Birmingham

Mr. Hobbs replied to Mr. Cotterill in the following letter, which appeared in the Times of the 15th of July:--

"To the Editor of the Times.

"Sir, –As you have given the publicity of your large circulation to a letter form Mr. Cotterill, in which my name is somewhat freely mentioned by that gentlemen, I trust to your sense of justice for permission to say a few words in reply. The question, however, is not one that primarily concerns myself, or indeed Mr. Cotterill (though he has given it a more personal aspect by a change in the words quoted from the Banker's Circular), but the Society of Arts, whose committee awarded a premium for a lock which has proved to be worthless. At the same time, I am not less sensitive of insinuations which really tend to lower my character for candour and honesty, though I will not resume to say that such is their object, than Mr. Cotterill can be of such as 'have for their object the lowering of his invention.'

"By 'insinuating' that I might, 'if so disposed,' have taken impressions and measurements of the interior of the lock invented by Mr. Saxby, and rewarded by the Society of Arts, and by speaking in different parts of his letter of the leisure and opportunities afforded me for examining it, Mr. Cotterill really leaves the impression on the mind of his reader that such was the case. It is a common trick in argument to begin by putting a suppositious case, and after rambling up and own the statement, and thereby mystifying the reader, to speak of it in the end as if the case were actually as the writer had supposed. These cobwebs to catch the unwary are easily brushed away by the simple statement that such opportunities were not afforded, and, in short, that they were quite unnecessary. The absence of any difficulty in the lock would have rendered any resort to such a means a mere waste of ingenuity.

"So much for the fact; and now with regard to the principle of the lock and the price at which it can be produced. I should

be most happy to submit the lock of Mr. Cotterill, for comparison with that of Mr. Saxby, to the gentlemen named by Mr. Cotterill, as having expressed their opinion of his lock, and leave to them the verification of my statement in the Journal of the Society of Arts–vix., that the lock of Mr. Saxby, which the committee of the Society judged worthy of a premium as a new invention, is constructed on precisely the same principles as the Yale lock, described in a paper read before the Society in January, 1852, and that it is precisely the same both in principle and arrangement as the Cotterill lock. The inferiority of its workmanship was a point particularly named by me; and, with regard to price, it is absurd to suppose, even such as it is, that it can be manufactured and sold for 2s.

"One word in regard to lock-picking. It seems to be taken for granted that I am open to challenges like that of Mr. Cotterill if only a sufficient inducement is held out in the shape of a pecuniary reward. I beg to assure that gentleman, and others who have mad the same mistake, that they will hardly catch me 'tinkering,' as it is elegantly expressed, 'with my basket full of instruments,' either upon their demand or that of any other man. When I came to this country it was as a competitor at the Great Exhibition; and in order to satisfy the public that the principle on which locks were constructed was not secure, I picked the locks then considered the most secure in the country, and in turn offered to submit my own to the same test. This is a privilege I still claim, without laying myself open to such demands as those I have felt it necessary to comment upon. Mr. Cotterill speaks contemptuously of my success on the Bramah lock. I have only to say that it did not rest with me to decide whether I had succeeded or not, but with a committee, whose impartiality it is both too late and too absurd to call in question. Your readers will remember that the gentlemen of the committee, whose decision was also unanimous, were the late Professor Cowper, of King's College, Mr. George Rennie, and Dr. Black.

"'Any common observer would suppose,' Mr. Cotterill remarks, 'from the eager manner in which the press gives publicity to every little movement of Mr. Hobbs, that no man in England could pick a lock; but in this I differ, being able to produce at any moment several poor working locksmiths capable of picking any lock in half the time Mr Hobbs occupies.' Mr. Cotterill does not perceive that the ease with which locks can be picked is my own argument, and I agree with him that there are many who can accomplish the feat in less time than myself. In conclusions, it is not in Mr. Hobbs that either the public or the press feel any

particular interest, but in the security of the enormous wealth confided to locks and keys so recently proved to be utterly valueless.

"I am, yours, &c.,
"A.C.HOBBS.

The editor of the Times appended a note to his letter to the effect that any future correspondence on the subject could only be inserted as an advertisement. The following remarks, which concluded the controversy on the "Saxby lock" affair, appeared in the Circular to Bankers, on the 23rd of July:--

"The remarks which we made in the Circular of the 2nd of July respecting the Society of Arts and their prize lock have created quite a commotion amongst the English lockmakers. But several of them who have addressed us appear to have mistaken the real object we had in view; and some of them have gone so far as to pervert the language we made use of altogether to suit their own purposes. Our attention was directed to the subject not to decide whether Mr. Hobbs or Mr. Cotterill, of Birmingham, could make a lock that cannot be picked; but to show that the committee of the Society of Arts, in awarding a prize for Mr. Saxby's lock, with Mr. Chubb as chairman, which Mr. Hobbs easily picked in three minutes with a small slip of steel, placed themselves in an unfavourable light before the public.

We did not take upon us to decide whether Mr. Hobbs' locks, or those manufactured by Mr. Cotterill or by Mr. Chubb, were the safest and best. The defense put forward on behalf of the committee by a correspondence in the Journal of the Society of Arts, to which we briefly referred last week, was that the 'great security,' as set forth in the prize list, meant great security against the attempts of the idle and mischievous; but it certainly never aspired to defy the systematic ingenuity of a professional lock-picker like Mr. Hobbs.

We hope the committee of the Society of Arts, for is own honor, will not acknowledge this weak defense; for Mr. Cotterill says –'He is able to produce at any moment several poor working locksmiths capable of picking any lock in half the time Mr. Hobbs occupies.' His condemnation of the Society's committee is, therefore, virtually stronger than our own; for he evidently does not rank Mr. Hobbs as a professional 'lockpicker,' but puts him on a footing with the 'poor working locksmith.' If, then, the Society of Arts be desirous of awarding prizes for the promotion of mechanical skill in its application to domestic purposes, it

ought to confer them upon those whose productions are most worthy; for in the present instance it is has been clearly shown that the lock for which the prize has been awarded can be easily picked.

"We have nothing to do with the controversy between the lockmakers and Mr. Hobbs. This is a matter they must settle amongst themselves. But we regard the question solely in a public light. Several extraordinary robberies have occurred that have rendered the security of locks an important desideratum in banking and other establishments; and whether the honor of accomplishing it be won by Mr. Hobbs or any one of our own countrymen, he is equally entitled to public support."

We have now arrived at the year 1854, which gave birth to such great events in connection with the Lock Controversy, the particulars of which will not soon be forgotten. In order that the following letters may be better understood, we shall here insert the official report of the discussion on Mr. Hobbs' paper "On the Principles and Construction of Locks," read before the Institution of Civil Engineers, February 21st, 1854.

"A succinct description was given of the various recent modifications generally introduced by makers of locks, and it was argued, that most of them were simply alterations of form, without materially adding to the security. As exception might, perhaps, be made in favor of Mr. Denison's lock; which was so constructed, that the bolt was shot by turning a handle, without the intervention of a key, which in fact was only used for placing the tumblers in a proper position, to allow the bolt to be withdrawn, or unlocked, by the handle, the keyhole being kept closed during the passage of the bolt; the key might, therefore, be always retained in the possession of one person, whilst the lock could be closed by any subordinate; this was important in banks and other similar establishments.

"The principle of the bolts being shot by a handle was not new, but the other arrangements were admitted to possess novelty.

"Mr. Whishaw's electro-magnetic lock, now exhibiting at the Polytechnic Institution, was explained, but was admitted not to be applicable to all the ordinary uses for locks.

"The principle of Mr. Cotterill's patent climax detector lock was then examined, and it was shown to be entirely based upon the Bramah lock, but was less secure in its arrangement,

inasmuch as the form of the key admitted of so little variation in the depth of the grooves, for moving the slides, that a lock, having six slides, might be opened by the end pressure of a piece of soft wood, and that any lock on that principle, with any number of slides could be easily picked by the pressure system.

"It was explained that the American permutating lock, which had been so fully described in the paper, was not intended for ordinary domestic purposes, but for banks and establishments requiring extreme precautions for security, and that the chief object in the introduction of Hobbs' moveable stump, or protector lock, was to supply a secure lock at a moderate price.

"In the course of manufacturing, as might be naturally supposed, the weak points of this lock had not escaped detection, and it was soon discovered, that although the principle was correct as long as the stump remained moveable, if by any means the stump could be held fast, the lock became one of the ordinary tumbler locks, and was as easily picked as the others. For instance, in a till or drawer lock, where the keyhole was parallel to the bolt, it was easy, by the insertion of a piece of watch-spring beneath the bolt, to catch and hold the stump, and to open the lock. This, however, was readily prevented by the insertion of a tongue in the backplate, fitting into a corresponding groove in the back of the bolt, thus cutting off all access to the moveable piece under the bolt; and further, to preclude access to the stump itself, a piece of steel was riveted into the front plate, reaching through the tumblers into a groove in the bolt, thus placing an effectual barrier between the keyhole and the stump. With these slight additions, which were not introduced, it was contended that locks constructed on the principle of the moveable stump might be considered secure.

"It was shown that Mr. Gaoter, who was connected with the establishment of Mr. Chubb, had succeeded very ingeniously in picking three of Hobbs' till locks, by the means which had been described; those locks, however, not having the additions for security which had been alluded to.

"This opening of these locks was admitted to be perfectly legitimate, showing slight defects in the details of construction, but demonstrating the correctness of the principle; and it was argued that it was only by such means that the manufacture of locks could be tested and improved, indeed, that the lockmakers were greatly indebted to Mr. Hobbs for showing them the weak points of the locks constructed prior to 1851.

“The manufacture of locks in this mechanical country had hitherto been conducted in the rudest manner, and with the most primitive tools; and whilst the price of common and insecure locks was incredibly low, that of locks of good construction was much too high to introduce them into general use. It was, therefore, the object of Mr. Hobbs, by the employment of good machinery, to produce locks of uniformly correct construction, on sound principles, and at such a modified scale of pries as would insure their general adoption; being assured that whoever might be the maker, the most secure locks, at the lowest price, would eventually take the lead with the public.”

It would appear from the following letters that Hobbs’ protector lock had been picked by Mr. Goater, some time before the meeting of the Institution of Civil Engineers on the 21st of February, and that statements to that effect were in circulation; and at the meeting referred to the modus operandi was explained by Mr. Hobbs himself. Without further preface, we now give the whole of the correspondence at length:--

The first letter from Mr. Goater appeared in the Morning Advertiser, February 24th.

“To the Editor of the Morning Advertiser."

“Sir, –About a year and a half ago I obtained one of Hobbs’ patent protector locks, and after carefully examining its construction, I felt convinced that I could pick it. I then prepared suitable instruments, and picked the lock in five minutes; this I did again and again, the third time it occupied only one minute and a half. I also picked another lock about two months since. Hearing the week before last that a paper on locks was to be read at the Institution of Civil Engineers by Mr. Hobbs, I requested my employer, Mr. Chubb, to allow me to operate on Mr. Hobbs’ locks in such a manner as to prove to the world, beyond any doubt, how easily they may be picked. Mr. Chubb then on Friday, the 10th of this month, put into my hands one of Hobbs’ locks, sealed up, the only access to the interior of it being through the keyhole. I had to make fresh instruments for this lock; I commenced operating upon it on the Monday morning, and in two hours I succeeded in picking it. I neither saw the keys nor the interior of this lock. I then picked two other of Hobbs’ locks under the circumstances detailed in the following certificate:--

"'London, Feb. 20, 1854.

"'On the 13th of February, Dr. Lobb and Mr. S. Maw called at the shop of Messrs. Hobbs and Co., Cheapside, and asked for, and purchased, two of Hobbs' best patent protector locks, with different keys. Each lock was accompanied by a label, stating that "the peculiarity of these locks consists in the arrangement of the tumbler-stump, it being attached to a moveable piece that works under the bolt, thereby preventing the possibility of ascertaining the proper position of the tumblers, which renders the lock secure against picking."

The locks were then taken to Messrs. Liddiard and Co., Friday street, where the bolt of one was locked out with its own key; the lock was then enveloped in paper, and sealed with the seals of Messrs. Liddiard, Sheriff, and Lobb, the keyhole only being left open. This lock was placed in the hands of John Goater the same evening, who returned it picked (still sealed up as when given to him) on Wednesday, the 15th of February. The second lock was then sealed in the same manner by Dr. Lobb, Mr. Copeland, and Mr. Arthur Lobb. This was delivered into John Goater's hands at nine o'clock on Thursday morning, who picked and returned it sealed as when given to him) at three o'clock the same afternoon. The keys of the first lock still remain sealed up in the custody of Mr. Sheriff, and those of the second in that of Mr. Arthur Lobb. Both these locks were fairly picked by the use of certain instruments, solely through the keyholes, and neither previously nor since has the undersigned John Goater seen either the keys or the interior of the locks.

"'We, the undersigned, append our signatures to vouch for the truth of the above statement, so far as each of us is concerned therein.

"'S. Maw, 11, Aldersgate-street.
"'J.M. Copeland, 2, Vernon-place, Bloomsbury-square.
"'William Lobb, 12,Aldersgate-street.
"'G.W. Sheriff, 61, Friday-street.
"'W. Liddiard, 61, Friday-street.
"'Arthur Lobb, Stock Exchange.
"'John Goater, 14, St. James's-walk.'

"In order to show there was no unfairness in the way I picked these locks, I explained the manner in which it was done to Mr. Carpmale, of Lincoln's inn, and on Friday last Mr. Carpmael purchased a lock at Mr. Hobbs' shop, which he sealed up

and gave to me; this I picked the same afternoon.

"It was not my intention to have explained the manner which I adopted in picking these 'unpickable American locks,' but upon second consideration, the plan being so simple, easy, and certain in its results, and knowing that the fact of their having been picked would set so many to try their hands at it, that it was sure to be discovered, induced me to alter my mind; therefore I described one of the methods at the Institute of Civil Engineers on Tuesday last; it simply consists in the application of a piece of watch-spring and two common picks.

"I am, Sir, your obedient servant,

"JOHN GOATER.

"14, St. James's-walk, Feb. 3, 1854,"

The following is the reply of Mr. Hobbs, in the same paper of the 25th of February:--

"To the Editor of the Morning Advertiser."

"Sir, –Amongst the advertisements in the Morning Advertiser of the 24th instant is a statement by Mr. Goater, foreman of Messrs. Chubb's establishment, which is calculated to convey to the public so erroneous an impression as to the security of the 'Patent American Lock,' that I deem it incumbent on me, in self-defense, to state explicitly the true facts of the case, and the only legitimate conclusions to be drawn from them.

"At a recent meeting of the Institution of Civil Engineers, after describing the peculiar advantages of my patent moveable stump lock, I took the opportunity of pointing out certain defects which I had discovered in its construction, which rendered it possible in the common till or drawer lock to introduce a piece of watch-spring, so as to fix the moveable stump or protector, and thus convert the lock into a mere ordinary tumbler or Chubb lock. Of course I made no secret of the fact, that so soon as this was accomplished there was no longer any difficulty picking it. I stated further, that upon discovering these defects in my own locks, which I had thus pointed out, I had lost no time in adopting such improvements in its construction as would effectually obviate them. These improvements I described to the meeting, and drew attention to some locks so constructed, which were then lying on the table.

"After I had thus openly explained the defect of a certain small class of my own locks, and the means by which these defects were now effectually removed, it was triumphantly announced to the meeting by Mr. Chubb that Mr. Goater had actually succeeded in picking that identical class of locks, and in the identical manner that I had already described. But more, or rather much less than this, it must be understood that the locks thus picked by Mr. Chubb's foreman, instead of being properly fastened to a drawer or box, were simply enveloped in paper, thus having the end of the bolt exposed so that a pressure could be applied by the hand, instead of requiring any instrument in the keyhole, as would be the case whenever the locks were really in use.

"And because Mr. Goater has thus achieved the very humble feat of bearing practical witness to the truth of what I stated only in words, the public are led to infer that he has proved the whole of my locks, including the 'Unpickable American Lock,' as insecure as their own. I say as their own, for it must be borne in mind that this wonderful triumph of Mr. Goater amounts simply to this: that through an oversight in the construction of a small class of my locks, he succeeded in so fixing the moveable stump that the lock became precisely the same as the ordinary Chubb or tumbler locks.

"I am, Sir, your obedient Servant,

"A. C. HOBBS
Cheapside, February 24, 1854."

The second letter from Mr. Gaoter is from the Morning Advertiser, February 27th.

"To the Editor of the Morning Advertiser."

"Sir –In replying to my letter to you in which I announced my picking the "Unpickable American Locks," Mr. Hobbs has thought fit, in his advertisement in reply, to drag the firm of Chubb and Son into the discussion. Allow me, Sir, to say that they are not parties in the matter. The question is: Have I picked the Hobbs' locks or not? He owns that I have done so, but he insinuates that it was 'after he took the opportunity of pointing out certain defects which he had discovered in their construction.' This, Sir, is simply untrue. I picked Hobbs' locks eighteen months ago. Again, he says, 'I made no secret of the fact, and lost no time in adopting such improvements in its construction as would effectually obviate them.'

Then, why did he not mention the insecurity of his locks in his lectures at the first meeting, and why did he then say that they were secure? And whey did he delay hinting at the insecurity of his locks until he knew that some of them had been picked by me? Nobody better knew the worthless character of the locks than Hobbs 'himself.' Such a notoriously clever lock-picker as Mr. Hobbs must have well known how easily they can be picked. Mr. Hobbs now questions the mode in which I picked his 'Unpickable American Locks.' At the meeting of the Civil Engineers he admitted, over and over again, the fairness of the whole proceeding. This is other of his after-thoughts.

"As a practical lockmaker, I assert that the principle of Hobbs' locks is bad and worthless; and I do not care what alteration he may make in it, I will pick them as easily as before. As to the locks which I picked, I simply chose locks sold by him as unpickable; but I can pick all forms and sizes, and the larger the better; and if fixed, still it makes not a bit of difference. I beg also to say that the pressure on the bolt was applied through the keyhole only. Now I would ask, Sir, what reliance the public can place on the promised improvement in locks, by a man coming from American to condemn the English locks, and who sells a very inferior article to those he condemns, some of them only taking one minute and a half to pick? In short, his ten shilling American locks are but a little better than a one shilling Birmingham lock. Again, on Tuesday week, he said his locks were perfect; but, as I have before said, the next Tuesday, having ascertained by movements, he acknowledged defects.

"In conclusion, Hobbs' locks have been picked; the bubble is burst, and let him blow as many more as he likes, they will all share the same fate. I have not yet done with Mr. Hobbs. It was under great and un-English provocation I drew the sword, but having done so, I have thrown away the scabbard.

"Yours, &c., JOHN GOATER.
"14, St. James's Walk,
February 25, 1854."

In reply to the above, the following letter and challenge appeared on the 28th:---

"To the Editor of the Morning Advertiser."

"Sir, –In reply to Mr. Goater's letter in the Morning

Advertiser of today, I shall simply refer, for the truth of the statement made by me on the 24th instant, to the printed official minutes of the Institution of Civil Engineers. Perhaps it may be as well to state that the lock claimed to have been picked was not, as Mr. Goater would have the public believe, "The American Lock,' nor was it in any respect similar in its construction. It was simply a lock constructed to be secure for all ordinary purposes, without materially increasing its costs. That Mr. Goater picked this lock eighteen months ago, and kept it a profound secret until the present moment will hardly be credited after the feeling he has displayed in his letters on the subject.

"But in order to give him an opportunity of proving his boast that he will pick all and any of my "Unpickable American Locks,' notwithstanding any alterations that I can make, I beg to inform him that one of my "Unpickable American Locks,' without additions, alterations, or improvements, shall be submitted to him, upon any terms, and for any length of time that shall be agreed to by a committee appointed for that purpose; and the sum of 200 guineas shall be deposited in their hands by me, to be paid to him in the event of his picking the lock.

"I am, Sir, yours, &c.,
"A. C. HOBBS.
"97, Cheapside, February 27, 1854."

"To Mr. Goater, in the employ of Mssrs. Chubb and Son."

\+ "Sir, –There are, in the employment of Messrs. Hobbs and Co., fifty skillful English mechanics, part locksmiths and part machinists, who, having read your bombastic advertisement in this journal of yesterday, come forward to rescue the article of our production (the protector lock) from the very sweeping condemnations you have thought fit to pass upon it. We wish to fix your attention to one point only at present, and that is, you affirm that you can pick Mr. Hobbs' protector lock with any alteration he may make: very well, then, you shall try; for we, the fifty workmen of Mesrs. Hobbs and Co., give you the following challenge –to pick this simple lock for £50, subject to regulations that may be agreed upon by a committee of five gentlemen; and in order that you shall not give us trouble for nothing, one condition is that you shall deposit £50 likewise, so that if you attempt to pick the lock and fail, we, the fifty men of Messrs. Hobbs and Co., shall have the £50 deposited by you. Should you not think fit to accept this challenge, which, be it remembered, is given in connection with the true meaning of your advertisement in this paper on Monday, the 27th of February, we

hereby give you notice that the omission shall be duly noticed, with additional points, from your advertisement before referred to. Anxious for a reply, we beg to remain,

"Your very humble servants,
"THE WORKMEN OF MESSRS. HOBBS & CO.
"97, Cheapside, 27th Feb., 19854."

The following extracts will show how considerable was the public interest excited by this incident in the Lock Controversy.

"LOCKS AND LOCK PICKING. –The workmen of Mr. Hobbs, the well-known lock manufacturer, have set a novel example of combination, which is somewhat remarkable at the present moment. A rumor having become current that the locks of their employer were as subject to the tampering touch of the 'pick' as that of most others, they, considering themselves and their skill compromised in the charge, have offered to deposit £50 against the like amount, to be forfeited on either side, in the event of any person fairly picking the American lock. This is in addition to the 200 guineas offered by Mr. Hobbs for a similar result."
—The Sun of Tuesday Evening, Feb. 28. 1854.

"THE LOCK CONTROVERSY. –Mr. Hobbs, the patentee of the American lock, in reply to some charges recently made against the security of that piece of mechanism, has offered 200 guineas to any one who can accomplish this task. It would further seem that the amor propre of the artisans in Mr. Hobbs' employ –some fifty in number, all British workmen –has been touched by the assertion of Mr. Goater, and they have entered an independent challenge for £50 against his picking the locks of their workmanship under this patent."
—The Globe of February 28, 1854.

"THE LOCK OF ENGLAND AND AMERICA. –It would appear, from a paper war now going on, that the lock question of 1851 is again open, a champion for the defeated manufacturers of that period having entered the lists. Mr. Hobbs, against whom the lance is poised, has accepted the gage, and with it has offered to reward the valiant knight with 200 guineas if he fairly sustains his menace. Nor are the large body of artisans who work for Mr. Hobbs silent spectators of the melee, but have undertaken, through the columns of the Advertiser, to wager £50 on the issue being in favor of their chief."
–The Standard of March 2, 1854.

The Morning Advertiser of March 1st contained the following from

Mr. John Goater:--

"Hobbs' Locks Picked.

"To Mr. A. C. Hobbs, and my 'very humble servants, the Workmen of Messrs. Hobbs and Co.'

"Gentlemen,–'Catch a Weasel asleep.'

"I am, Gentlemen, yours very truly,
"JOHN GOATER,
"The picker of four of Hobbs' Locks, all warranted by
"Mr. Hobbs as 'secure against picking.'
'14, St. James's Walk, February 28, 1854."

The following concluding letter from the workmen in the employ of Messrs. Hobbs and Co. appeared in the Advertiser of March 4th, 1854:--

"HOBBS LOCKS.

"To the Editor of the Advertiser."

"Sir, –Mr. Goater, in the employ of Messrs. Chubb and Son, has publicly boasted that he could with the greatest ease pick any of Hobbs' patent protector locks, notwithstanding the improvements which Mr. Hobbs has added for their more perfect security. Feeling satisfied, as practical workmen employed in the manufacture of these locks, that he was unable to make his boast good, we offered at our own risk to take him at his work, and stake £50 on the issue.

"Mr. Goater, with an assumption of dignity rather inconsistent with his position, declines this fair and open challenge from workmen employed like himself, and like him, of course, personally interested in the value and reputation of the locks they are engaged in manufacturing; and as he thus refuses the opportunity we have offered him of establishing beyond dispute what he has so freely and so easily asserted, we feel perfectly satisfied in now leaving the result with the public, assuring him, however, that should it be necessary to select a champion 'to maintain the character of English locksmiths against American (or even native) misrepresentations,' we, as members of that body, will hope to find one not only ready to correct the errors of others, but with sufficient candour to acknowledge merit, and honorably confess to a fair defeat.

"We remain, Sir,
"Your obedient Servants,
"The Workmen of Messrs. Hobbs and Co.
"97, Cheapside, March 3, 1854."

The next lock-picking experiment which we have now to notice is one of considerable importance, and is the only unsuccessful public one which has resulted from Mr. Hobbs' manipulations. The circumstances which led to it, and the incidents connected therewith, are so fully described in the reports from the Manchester Guardian, (which we shall insert at length) that have but little to state in addition thereto.

(From the Manchester Guardian of Saturday, April 29, 1854.)

"Circumstances, which may be gathered from the following statement, led Mr. Edwin Cotterill, of Birmingham, the patentee of a safety lock called "The Patent Climax Detector Lock.' to challenge Mr. A. C. Hobbs (who picked the Bramah locks and those of Messrs. Chubb and Son) to pick his lock, offering to pay him fifty guineas if he succeeded within the time specified. After much correspondence, it was finally agreed that the lock to be subjected to this clever picker should be one upon an iron chest, sold some months since to Mr. B. Fothergill, consulting engineer, of this city.

As the lock and key had been for some time out of Mr. Cotterill's possession, it was agreed that the patentee should be allowed to take the lock off in the presence of Mr. Fothergill, and minutely examine it, and then reaffix the lock to the door of the safe. This having been done, a meeting of a few gentlemen was held at Mr. Fothergill's offices, Queen's Chambers, on Thursday morning week, for the purpose of making the requisite arrangements for carrying out the test. Besides Mr. Cotterill and Mr. Hobbs, there were present Mr. Richard Roberts, C.E., Mr. Fothergill, C.E., Mr. Charles Beyer, M.E., Mr. J.F. Roberts, Mr. Harland (of the Manchester Guardian), and Mr. Morris.

The agreement, written and signed in duplicate, was then read over, and it was fully assented to on both sides. It stated that Mr. Cotterill had done to the lock, in the presence of Mr. Fothergill, just what the agreement authorized and no more. Mr. Cotterill then named Mr. Roberts as the gentlemen to remain with Mr. Hobbs during the visit he was to be allowed to make to the lock, for the purpose of taking measurements from the outside of

the keyhole for adjusting his instrument by which to pick the lock.

This operation commenced at 11:6 a.m. on Thursday; at 11:15 Mr. Hobbs removed the nozzle-drop; and he concluded taking measurements at 12:24 p.m., thereby occupying one hour and eighteen minutes in this visit to the lock having the remainder of the day to make any alteration in the instruments he thought necessary, and this was granted in addition to the twenty-four hours allowed for actual operation. The outer brass shield of the lock was then carefully sealed up by Mr. Roberts, so that the lock could not be subjected to any further experiment till that should be authorized.

"Yesterday (Friday) morning, at half-past ten, the gentlemen already named reassembled at Mr. Fothergill's offices, together with Mr. Salt, secretary of Liverpool Polytechnic Society, Mr. Weild, engineer, and Mr. Morris, a reporter. Again the agreement was read over, and it was intimated that the words 'one entire day' must be construed as twenty-four hour consecutive hours. Mr. Hobbs said he had made his instrument and was ready to begin. Mr. Cotterill drew a cheque on the Birmingham Banking company for £52 10s., payable to Mr. Hobbs or bearer, and handed it to Mr. Richard Roberts. Mr. Hobbs then said that he wished to observe that this challenge was not of his own seeking. At the Great Exhibition of 1851 he was challenged by a Mr. Cotterill to pick his lock, and if he had thought that it was at all different in principle from those of Bramah or Chubb, he would have tested it; but thinking it to be much the same as Bramah's, he declined the challenge. Then his name was put forth in Mr. Cotterill's circulars and advertisements to the effect that he had been fairly challenged to pick the lock, and had declined.

This went on for some time; until he (Mr. Hobbs) reading a paper on locks at the Society of Arts, he had referred amongst others to Mr. Cotterill's lock, not with any view of calling him out. On this Mr. Cotterill again challenged him, and he again declined; and his name was again put in Mr. Cotterill's window as not daring to test his lock. [Mr. Cotterill said that what was stated was –"Mr. Hobbs has declined my challenge."] –He did not wish to test the lock; but he had certainly felt annoyed by his name being thus used, and at length, when Mr. Fothergill wrote to him, he took up the challenge; believing that otherwise his name would be again held up as shrinking from the test.

He wanted everything during this trial to be perfectly

smooth and pleasant; he would throw aside all feeling of annoyance, and ask the gentlemen present to look upon the matter simply as the solving of a mechanical problem. Whether he succeeded or not, everything he did should be made public; the instrument he would use should be shown, and its application to the lock; nothing should be concealed; and he hoped everything would be conducted with the best feeling and understanding.

–Mr. Cotterill said that Mr. Hobbs had represented him as acting upon the offensive. This he must deny; he was merely upon the defensive. Mr. Hobbs had spoken in disparagement of his lock; had called it a Bramah lock, as if there was no difference, and said it could be easily picked. His only object was to prevent these statements being injurious to his reputation as the patentee of this lock, and to prove its security. As Mr. Hobbs had publicly spoken of the ease with which he could violate the lock, he thought it the best method to give him the opportunity of doing so. Rumor was sometimes stronger than truth; and what Mr. Hobbs had positively stated would be believed extensively, and he was aware that what he had stated was working to his (Mr. Cotterill's) injury; therefore he felt it imperative upon him to bring his lock and Mr. Hobbs to the test. He offered him a handsome inducement; and if Mr. Hobbs was convinced that the lock was in substance a Bramah's, why it would be so much easier for him to operate upon it.

Mr. Hobbs, as a maker of locks himself, must influence the business of others and his own by showing the insecurity of other locks; for he was thus in a great measure and by implication proving the security of his own. For these reasons he felt bound to challenge him; and when Mr. Hobbs declined that challenge, he thought it legitimate to let the public know he had declined. He had never spoken one word disrespectfully of Mr. Hobbs; he had merely stated facts; he had published his own letter and Mr Hobbs' reply; he had offered no comment of his own, and he did not see that Mr. Hobbs had any real ground for feeling annoyed.

—Mr. Fothergill explained that, happening to attend one evening a meeting of the Institution of Civil Engineers, he heard Mr. Hobbs read a paper on locks, in the course of which he named Mr. Cotterill's lock. He (Mr. Fothergill) meeting Mr. Cotterill at Birmingham shortly after, to pay him for the safe with his patent lock now to be experimented upon, told him what Mr. Hobbs had said. This led to the challenge: he had been a medium of communciation between them, and it was at length agreed that the lock on this safe should be the one subjected to the test. Mr.

Cotterill said that that safe had been sold and delivered some months, and before he had ever dreamed of Mr. Hobbs making experiments upon it; therefore it would be seen at once that it was not a lock which was made for the purpose of resisting any such extraordinary operations. When Mr. Hobbs had referred to his lock at the Institute of Civil Engineers would be between two and three months ago.

"All preliminaries having been amicably settled, Mr. Roberts broke the wax round the lock, which having been repeatedly locked and unlocked with the key, was finally locked, and the hands of Mr. Cotterill, to prevent any access to them. Mr. Hobbs produced a small rod, which he had used in taking measurements the preceding day. The lock has twelve radiating slides, and as these marked the sides of the rod, he filed away the marks till he got a sort of model for his instrument. This pick-lock (which must have occupied some days in constructing) was the most ingenious tool of the kind he ever saw; consisting of a series of twelve radiating iron needles or wires, with screw ends, which could be gently inserted, and each in turn carefully propelled forward till it reached the requisite point. Where it did not at once act, as was most usually the case, a little filing was applied where its smoked surface showed that it impinged on the slide within. Before beginning, Mr. Hobbs, by means of an instrument, raised the nozzle-drop, which is to guard the interior of the lock against burglarious efforts.

"Mr. Hobbs commenced to use his instrument at five minutes after eleven a.m. yesterday, and for many hours applied himself diligently to his task, advancing but slowly in the adjusting of needle after needle to the requisite length and form. At five o'clock, after he had been engaged about six hours, he was still quietly seated before the chest, occasionally poking in this instrument; and we understand that with the exception of ten minutes or a quarter of an hour for some light refreshment, he had remained steadily at his work throughout the day. At 8 o'clock Mr. Hobbs left the room for a time, to get some tea; he returned at a quarter before nine, and soon afterwards resumed his efforts. About a quarter before ten o'clock this instrument broke, or became unsoldered; and accompanied by Mr. Weild, with some difficulty, he succeeded in inducing a watch-maker in Salford to solder it. He returned a few minutes before eleven o'clock and resumed his labors. There remained in the room with him, but not near him, Messrs. Richard Roberts and J.F. Roberts, Mr. Weild and Mr. Cotterill. He appeared determined to continue his efforts throughout the night, and said he should not work

after eleven on Saturday morning; when the twenty-four hours allowed for the trial will have elapsed."

(From the Manchester Guardian of Wednesday, May 3, 1854.)

"In the Guardian of Saturday, we gave an account of the challenge by Mr. Edwin Cotterill, of Birmingham, patentee of 'The Patent Climax Detector Lock,' to Mr. A. C. Hobbs, the celebrated American locksmith, whose picking of Bramah's and Chubb's locks created so great a sensation during the Great Exhibition, to pick that lock within 'one entire day of twenty-four consecutive hours,' and, if successful, Mr. Cotterill bound himself to pay him fifty guineas; if unsuccessful, all Mr. Cotterill required was to receive from a committee of gentlemen, appointed to witness the experimental test, a certificate to that effect.

In our last, we published an agreement signed in duplicate by Mr. Cotterill and Mr. Hobbs, and described the commencement of the experiment and the progress supposed to have been made by Mr. Hobbs from Friday forenoon at 11:5 up to the same hour on Friday night, being just twelve hours, or half the time allotted for the experiment. In a later edition of our Saturday's paper, we briefly stated the fact of Mr. Hobbs having failed to pen the lock within the twenty-four hours. We now briefly sketch the proceedings during the latter half of that time, and those attending the subsequent examination of the lock.

In the third edition of Saturday's paper we stated that Mr. Hobbs said he had succeeded in lifting or raising ten of the twelve slides which the lock contains; but this was subsequently proved to be an involuntary error of Mr. Hobbs'. He might have raised ten slides a certain portion of the distance necessary; but it was clear that he had not raised one of them sufficiently, and that if he had even forced eleven of them into the proper position, the lock could not have been opened.. Indeed, if all had been raised by his ingenious instrument, in turn, he could not have opened the lock, which will yield to nothing but a simultaneous action on all the twelve slides at once, and this could only be effected by the legitimate key.

"We stated that up to eleven o'clock on Friday night Mr. Hobbs continued his efforts to open the lock; four gentlemen remaining at the other end of the room, so as not to disturb him by over close and inquisitive inspection of his labors. These gentlemen were, Mr. Richard Roberts, C.E., and his son, Mr. J.F. Roberts; Mr Weild, mechanical engineer; and Mr. Edwin Cotterill,

the patentee of the lock under trial; the other gentlemen having retired for the night. After having got his lock-instrument soldered, Mr. Hobbs resumed his labours a few minutes before eleven o'clock on Friday night. After continuing before the lock till 12:30 (midnight), he said he would go and recruit himself by a few hours' sleep, and would resume his work at five in the morning. He accordingly proceeded to the Royal Hotel, and went to bed. The four gentlemen remained in Mr. Fothergill's offices, Queen's Chambers, awaiting his return.

He was back at his post a little earlier than the time named, and recommenced his labors at 4:26 a.m., Saturday. At 7:45 a.m. he again suspended his operations for further rest and breakfast; and he once more sat down before the hitherto impregnable lock at 9:20 am. A few minutes before the expiration of the twenty-four hours, he quietly arose, and said, 'The lock's yours; I give it up.' The committee having reassembled, Mr. Hobbs repeatedly said he had not succeeded, and that all that remained was to have the lock taken off and examined. Mr. Cotterill produced the sealed packed containing two keys for the lock; both these were tried, and the lock was opened, and found both to lock and unlock freely; thus proving first that Mr. Hobbs, in his operations, had not injured the interior; and, second, that no accidental obstruction had resulted during his experiment, so as to raise up an unexpected obstacle to his success.

Mr. Cotterill's workman was then called in, and in the presence of the committee and the two parties to the trial, and several witnesses, took off the lock, and, removing the inner plate, revealed the whole of its construction; so as to show that it was no little addition introduced for the occasion, but the construction of the lock itself, which had baffled the ingenuity of Mr. Hobbs. A few moments examination sufficed to reveal to him that this latter was the fact.

There were two obstacles, either of which would singly have defeated his attempt, but combined, they rendered the actual difficulty insuperable. One of these was a detector. Mr. Hobbs next examined another and still more formidable obstacle to his success, consisting of an outer ring of steel around the circular brass lock; and every slide on being pushed, by key or instrument, from the centre to the periphery, at first impinges on this external steel ring; but on increasing the pressure applied simultaneously by the regular key to all the twelve slides, they force themselves, by means of a sloping or bevelled

edge, into a groove in this outer ring, and till all the slides do this at once, the lock cannot be opened.

–Mr. Hobbs examined this portion of the construction carefully, and then said: 'Really it is very ingenious. I believe it to be a regular, fair, commercial lock, and I really think it is a very pretty arrangement, and I think great credit is due to Mr. Cotterill. A man might work a lifetime, and never overcome it.' Mr. Hobbs was then asked (after he had minutely examined the internal part of the lock) whether he would again encounter with the lock upon the same terms? He answered, no; adding, that if allowed a month, he could not accomplish the task. After some further examination and conversation, Mr. Hobbs, turning to Mr. Cotterill, said: 'Well, you will make the most of this in trade, and you have a perfect right to do so; but, at the same time; I hope we shall not have any personalities.'

–Mr. Cotterill: 'Mr. Hobbs, I confess I think there has been a little aggression on your part; but I dislike personalities as much as any one, and I hope we shall part friends.'

–Mr. Hobbs: 'I have never made any attack on you. I have described your lock in public and private, as I have seen it, and as I saw it at the Great Exhibition. This lock [one of Mr. Cotterill's earlier make, which Mr. Hobbs had bought and experimented upon, and made his instrument by,] was bought within six months; and as such I have described that lock.'

—Mr. Cotterill: 'I could pick a Bramah lock in a minute; I have tried to pick my own, and failed; and, as its inventor, if it had weak points, I may be supposed to have known them. The lock I make now I consider inviolable, and I shall take my stand upon it; for I may now say that it is a practical impossibility to pick my commercial lock.'

–Mr. Hobbs: 'I was just as near picking it when I first put the instrument in it yesterday, as I was at the last moment.'

–Mr. Cotterill then expressed his acknowledgments to the gentlemen of high mechanical knowledge and skill, who had given their valuable time and attention to this experiment, and one which none would attempt to gainsay. Much had been said than that it had passed the severe ordeal of Mr. Hobbs' manipulation during so many hours. He felt that Mr. Hobbs had in this instance acted very handsomely, in making the admission that the

lock was a good one, and that if he had tried for a month he should not have succeeded. He hoped that in these contests every man would try to rise higher, and not to drag others down to a low level. He thought his lock had now that security about it as to demonstrate that it was much easier to take care of money that to get it; and he hoped the commercial community of Manchester would, therefore, give him a share of their patronage.

–[Laughter] Mr. Hobbs: 'It is said, "Let him laugh who wins;" but here, I think we are all winners. Mr. Cotterill wins reputation for his lock; and I have won something, for I have learned something by it.'

–Mr. Cotterill then said that Mr. Hobbs had been kind enough to offer him the same privilege to test his (Mr. Hobbs') lock upon [we think] a three-inch scale. He had declined accepting that challenge for himself; but, if Mr. Hobbs had no objection, he would accept it for his young man, reserving to himself the privilege of constructing the instruments only. –Mr. Hobbs said he had no objection whatsoever.

"Mr. Cotterill having requested the committee to furnish him with the certificate stipulated for in the written agreement, the following was hastily drawn up, read over to both parties and to the committee, and when Mr. Cotterill, Mr. Hobbs, and the committee had expressed their full approval of it, it was signed by the committee and by other gentlemen who had been more or less witnesses of the experiment:--

"'Queen's Chambers, Manchester, April 29, 1854.

"'We, the undersigned, being the committee appointed to see that the "Patent Climax Detector Lock" of Mr. Edwin Cotterill, of Brimingham, should be fairly subjected to the manipulation of Mr. A. C. Hobbs, of London, during twenty-four consecutive hours, to be picked or opened by him, with an instrument or instruments constructed by him or for him for the purpose, do hereby declare that the experiment has been fairly tried, during the time, and under the conditions of the written agreement in duplicate, signed by the respective parties; and that Mr. Hobbs has failed to pick the lock, and has declared that it is a very ingenious one, and that if he had tired to pick it for a month, he should have failed.

"'RICHD. ROBERTS, C.F. J. HARLAND.
"'C. BEYER, M.E. THOS. MORRIS.

"'Signed in the presence of us, who have also witnessed the experiment,

"'BENJN. FOTHERGILL, C.E.
"'W. WEILD, M.E.
"'PETER J. LIVSEY, C.E.
"'J. F. ROBERTS.'

"The experiment having thus terminated, and the greatest good feeling prevailing, Mr. Cotterill invited Mr. Hobbs, the committee, and other gentlemen, especially the four who had remained in the room (with the exception of a short absence for refreshment) during the twenty-four hours, to partake of luncheon, at the Clarence Hotel. This invitation was accepted, and a very pleasant afternoon ensued. Amongst the toasts were —'The Queen;' 'The President of the United States;' 'The committee;' 'Mr. Cotterill;' 'Mr. Hobbs;' 'Mr. Richard Roberts,' C.E.' 'Mr. Benjamin Fothergill,' consulting engineer; 'Mr. Bennet Woodcroft,' of the Great Seal Patent Office; "The Press, &c."

In this experiment Mr. Hobbs had evidently miscalculated the chances of opening the lock. It is only fair to state that it was not a test lock, as it had been sold in the regular way of trade, affixed to the door of an iron safe, some months prior to the experiment being made. That it was a better and a more secure lock than the earlier locks made by Mr. Cotterill must also be admitted. By referring to the description of Cotterill's lock [at page 489], the action of "the ring" will be understood; and a drawing of a similar instrument to the one used by Mr. Hobbs in the experiment will be found on page 314, the only difference being that the former is suitable only for a lock with six slides, whilst Mr. Hobbs' pick was constructed for the lock in question, which had twelve slides.

In operating upon a Cotterill's lock with this instrument, the sliding wires (**e**, **figure 136**) are first all set free. It is then inserted in the lock, and pressure is applied to feel which of the slides bind, when such slide is forced into its true position by the wire in connection with it, and so on with the remainder. The manipulation requires a firm as well as a great delicacy of touch. We are not surprised that Mr. Hobbs did not succeed in picking the lock.

Many of the remarks made in reference to the Bramah lock equally apply to this one. We admit that a badly-made Cotterill

lock is not difficult to pick by a clever lock-picker with an instrument similar to **figure 136**; but a lock with twelve slides and well made, containing both the "ring" and the "double click," we consider sufficiently inviolable for any purpose for which a lock may be required.

We have shown in the course of the work how Bramah's, Chubb's, and Cotterill's locks had been subjected to the severe trial of being operated upon by Mr. Hobbs, who is acknowledged to be one of the most ingenious and clever engineers of the day, and the result of his manipulations in respect to each of them; and also how Hobbs' protector lock had been picked by Mr. Goater. We now come to the affair of Goater's tampering and the defiance lock of Parnell and Puckridge at the Crystal Palace, Sydenham, which will form a contrast to the honorable and open course pursued by Mr. Hobbs in respect to his experiments with the locks before described.

It would appear that at the opening of the Crystal Palace, Sydenham, in 1854, Messrs. Parnell and Puckridge, like many other manufacturers, rented space in the building for the purpose of exhibiting their locks and other goods. Amongst the former was a "Defiance" lock, with a label attached thereto in the usual way, offering a reward of two hundred guineas to any one who should fairly pick it, and a pamphlet was circulated containing the terms and conditions of such trial. The lock was a twelve-inch one-sided rim deadlock, very strongly made, and with the cap-plate perforated so as to show the working parts of the interior, and sufficiently open to allow the hand to pass through. It would further appear from the evidence given at trial which resulted form Goater's conduct, and from Lord Campbell's charge to the jury, that Mr. Goater, who was then a foreman in the employ of Messrs. Chubb and Son, of St. Paul's Churchyard, did in the absence of Messrs. Parnell and Puckridge, and without notice to them, and before and after the hours when the Crystal Palace was open to the public, clandestinely get access to the lock possessed himself of it, and made a key to it. When the trick was sufficiently ripe for execution, he (Goater) addressed to Messrs. Parnell and Puckridge the following letter:--

"Saturday, August 5th, 1854.

"Gentlemen, –I beg to acquaint you that I am prepared to put the bolt of your lock back this 5th day of August; and hope to

meet you at the Crystal Palace this morning between the hours of eleven and twelve of the clock.

"I am, Gentlemen,
"Your obedient servant,
"J. GOATER.

"To Messrs. Parnell and Puckridge."

Messrs. Parnell and Puckridge having discovered that the lock had been tampered with, refused to submit that particular lock to Goater to experiment upon, but proposed to send to their depot in the Strand for another similar in all respects, which was to be screwed on to a door suited to the purpose; and after adjusting the usual preliminaries, Goater was to be allowed to commence operations. This proposal was declined by Mr. Goater; when, to prevent any misunderstanding, the following notice was delivered to him by Messrs. Parnell and Puckridge:--

"August 5th, 1854.
"Mr. GOATER,

"Sir, –We beg to inform you, that we entirely ignore your proceedings in respect of the attempt to open our lock in our absence, without due notice, and in defiance of the printed terms and conditions, laid down by us, of such trial; and we hereby give you notice, that we are quite willing to submit a lock precisely similar to that with which you have experimented for the purpose of attempting a similar experiment upon, provided that it be conducted in our presence, with due notice, and upon terms and conditions to be agreed; and we shall be prepared to submit such a lock to you on Tuesday next, at one o'clock, p.m., in the Crystal Palace, in such a situation or position as may be determined.

"We remain, Sir, ours, &c.
"PARNELL & PUCKRIDGE."

In accordance with the latter notice, Messrs. Parnell and Puckridge attended at the Crystal Palace with the second lock and their friends; and "Mr. Goater and the Messrs. Chubb were at their stand in the building, but did not come forward." In two days afterwards Mr. Goater send to Messrs. Parnell and Puckridge the following answer, which was inserted in the public papers:--

"Parnell's Patent Lock Picked.
"6, White Lion Buildings, White Lion Street, Petonville,

"August 10, 1854.

"Gentlemen, -On Saturday last I fairly picked your 'Patent Defiance and National Lock,; at the Crystal Palace, in the presence of several witnesses; for picking which particular lock you affixed a label offering 200 guineas reward. I then and there again offered to pick the same lock in your presence, and before some hundreds of persons then present.

"This offer you cowardly declined, and dishonorably refused to pay me, a working man, the reward I had earned; and then you took away the lock and label amidst the groans and hootings of spectators.

"Mind, I do not decline your present challenge; but until the 200 guineas you owe me are paid, either from your own sense of justice, or the compulsion of a verdict of a jury, I decline having anything to do with Messrs. Parnell and Puckridge. I confidently appeal to a host of gentlemen connected with the Crystal Palace Company, who were present on the occasion, for the truth of what I state.

"I am, Gentlemen,
"Your obedient Servant,
"JOHN GOATER.
"Messrs. Parnell and Puckridge, 52, Strand."

Messrs. Parnell and Puckridge replied to the above in the following letter, which was inserted in the Daily News and Morning Advertiser of August 12th:--

"Parnells' Patent Defiance Lock has not been picked and is unpickable.
"52, Strand, August 11, 1854.

"To Mr. John Goater, Messrs. Chubb and Son, Lockmakers.

"Sir, -Your very specious but lame reply to our challenge will not serve the purpose you desire.

"What you assert and wish the public to believe you have already done fairly, surely you can do again. You must admit that you did not even 'put back the bolt' of our lock in our presence, much less 'pick the lock fairly' before us.

"Why decline to pick any other lock than the one referred to by you? Which, be it remembered, had been without its cover

plate, and unprotected in any manner, exposed openly upon our stand in the Crystal Palace for a considerable time, you and others having ready access thereto, if you chose to violate propriety and our exclusive rights by trespassing upon our property. Moreover, it was from off that particular lock that you admitted having broken the label referred to, not while operating on Saturday morning (the time you stated you proposed to 'put back the bolt of our lock,' not pick it), but previously to Friday morning,' for it was only upon Friday morning that we found that that lock had been removed from off our stand, opened, chipped, and scratched all over, bearing strong and unmistakable evidence of having been opened and worked upon, and the label forcibly broken off from it, evidently with a view to render it more portable and the easier to be removed from our stand, or probably out of the building, without exciting observation.

"That you broke the label off that lock was admitted by you.

"That on Saturday, when we received your note at 10 o'clock appointing 11 to 12 o'clock the same day, for the purpose, as you state (of putting back the bolt of 'your lock'), we believe we saw at once the explanation of the extraordinary state in which we found our lock on the previous day, and but for going to the Crystal Palace on Friday morning last, we might, in our confidence in the sacredness of our stand and the goods thereon after the ours at which the attendants leave, and before the usual hour of their admittance in the morning, have been in ignorance of; and but for which we should have been ready to fall into your proposition and plan.

But upon entertaining the suspicion that something most unfair had been practiced upon us, and which suspicion we considered was confirmed afterwards, determined us to act only under advice, feeling that you were not, by your own admission, entirely free from the suspicion which we saw good reasons for entertaining, and we would ask any honorable and disinterested man if he does not agree with us that under those circumstances you were not in a position to persist in your attempt, and that we were justified in objecting thereto.

We cannot but remember that the temptation of 200 guineas is great to any working man; moreover that the opportunity of asserting even for a short time, and without regard to truth, that the Defiance lock had been picked, is probably a greater temptation to a rival patentee and lock manufacturer whose locks have been picked. If you have no other object to serve than that

which you stated, why did you not rather accept the proposition that we should send to our shop in the Strand for the fellow lock, which you could not be charged with having tampered with, or making instruments representing the key, from having had access to the working parts of the lock? And if you had succeeded in picking that lock, the matter would have been set at rest on Saturday last. This, we felt assured, would have been done by any competent person who had confidence in his ability to pick our patent Defiance lock.

"In conclusion, we beg to remind you that our object is not an idle display or desire to figure unnecessarily in print. The extent of our business demands our whole time; our object is to defend our property from unfair and improper attacks; and our confidence, as well as that prat of the pubic generally in the high character of our locks, has been increased rather than diminished by your conduct towards us and our lock.

"We are, Sir, your obedient Servants,

"PARNELL AND PUCKRIDGE."

We extract the following from a pamphlet on this subject, published by Messrs. Parnell and Puckridge:--

"The effrontery and indecency of this letter require no comment; every man expresses himself in the language congenial to his temper and habits.

"We are amazed at any person of character or respectability countenancing Mr. Goater in this attempt to cheat us of two hundred guineas. There were some who appeared to us to approve of his conduct, and who assisted, we understand, in aspersing us, and circulating injurious reports.

"A very unfair and damaging notice of the proceedings having been furnished to the public papers by interested parties, our friends, seeing the inevitable tendency of any further discussion to degenerate into personal altercation, and fearing lest from the general persuasion of mankind, that where much is positively asserted something must be rue, we might be injured in our business, advised us to require Mr. Goater to retract and apologize, and in default of his doing so to bring an action against him. Mr. Goater having declined, on the contrary persisting in his injurious statements, we commenced proceedings at once.

The case was tried at Guildhall, before Lord Chief Justice

Campbell and a special jury, on the 21st of December, 1854. The defense was rather remarkable. Mr. Goater, who was examined, told by the jury he had not seen our notice requesting of the public not to touch the goods, nor our pamphlet (though we were distributing it generally at our stand) wherein we distinctly stated preliminaries should be settled with us, nor our printed preliminaries (which some days before his exploit one of his employers, Mr. Charles Chubb, procured for us at our depot, 52, Strand). Of these Goater never heard. However unaccountable and suspicious it may seem, he saw nothing on our stand but the lock and label. None so blind as those who do not choose to see. The charge of his lordship on this part of the defense renders any comment form us superfluous.

"He also attempted to persuade the jury he could pick any lock as well as ours, but after four months' preparation he altogether failed to satisfy the jury either that he had fairly picked or could fairly pick our lock. Exposed as our lock was, any ordinary workman, provided with an uncut blank key, by removing the cover-plate and cylinder for a few minutes(and we are sure our lock was taken to pieces by some one) could complete a key in a few hours. A key could, without very much mechanical ingenuity or skill, be made to any lock under similar circumstances.

"Even the clap-trap operation of making a key in open court to one of our small inferior locks was but a sham and a deception. This lock was in his possession for several months, and he had his supposed blank ready prepared, but which, with becoming gravity of course, he passed through the ceremony of smoking at the candle. He might as well have dipped it in the Thames.

"If Mr. Goater could pick our lock by this simple process, how can anyone give credit to certain stories about convicts, trained and skilled in all the mysteries of smoked blanks and skeleton keys, being offered a free pardon and a reward of £100 if successful in picking inferior lever locks, and after months spent at it, giving up the attempt. (See Chubb's Pamphlet on Locks.) Mr. Goater is a very clever and ingenious mechanic; he prides himself on his powers of lock-picking. He showed very great ingenuity in picking some of Mr. Hobbs' Protector locks, before the late improvements in them. We are well aware of his capabilities; and, in his assault on us, he had more than one motive to stimulate him to put forth his whole strength. In case of success, the honor and glory of crushing us –the advantage to

his employers from an unwelcome competitor being pushed out of the way –and the premium of two hundred guineas; and, in case of failure, damages, costs, and loss of character. He failed. If success were possible he would not have failed.

The trial above refereed to took place as stated, the following account of which we here copy from the Daily News of December 22, 1854:--

“COURT OF QUEEN’S BENCH, DECEMBER 21."

“Sittings at Nisi Prius at Guildhall, before Lord Campbell and Special Juries.–Parnell and another v. Goater –The Battle of Locksmiths –Alleged Libel.

“Sir F. Thesiger, Mr. Montagu Chambers, and Mr. Needham, appeared for the plaintiffs; the Attorney-General and Mr. D.D. Keane represented the defendant.

“This was an action for an alleged libel published in the Morning Advertiser, reflecting on the characters of the plaintiffs, the proprietors of a patent lock called “The Defiance Lock,” brought by them against the defendant, as the writer of the article complained of, a workman in the employ of the Messrs. Chubbs, the patent lockmakers, and who, it will be remembered, had succeeded in picking the lock constructed by Mr. Hobbs, the American.

“The plaintiff, Mr. Parnell, stated that his firm had exhibited their lock in the Crystal Palace, and appended to it a label offering a reward of 200 guineas to any one who should succeed in opening it. Goater, the defendant, superintended the stall kept in the Crystal Palace by the Messrs. Chubbs, and had therefore many opportunities of seeing the plaintiffs’ lock. On the 14th of July the defendant came to the plaintiff, and after some conversation remarked it was foolish to offer the reward, for they would surely have the Yankee, meaning Mr. Hobbs, down upon them, as he would do anything for money; to which he had replied that anyone was welcome to endeavor to pick the lock, subject to the preliminaries. Goater then went away.

On the 4th of August, having gone to the Crystal Palace, he found that someone had been tampering with the lock. It had been misplaced; the iron stay by which the label offering the reward was attached to the lock was broken, the skeleton cover-plate had been removed, and had been but partly screwed on again, and there

were marks of fingers and thumbs on the interior works. On the following day a note was sent by the defendant to plaintiff's shop, in which he stated he was prepared to pick the lock, and hoped they would meet him at half-past eleven that day. On receiving the note he went down to the Crystal Palace, where he arrived about half-past eleven, before the doors were open, as it was a Saturday. The defendant asked him if he had received a note from him. He replied he had, and asked him if he meant what he had written. The defendant said he did, and that he had prepared all his instruments for the purpose, on which the plaintiff observed that the lock had been previously tampered with. The defendant said he had broken off the label in getting out his instruments. He also said he wanted nothing for doing it, nor did he want to make it public, and that if the plaintiff would take the lock into Mr. Deane's room he would show him how he could pick it. Mr. Charles Chubb subsequently said that Goater could do it, and that he had himself found a way by which the lock could be made undeniably safe. The plaintiff then said he did not believe that either Mr. Chubb or his man could pick the lock fairly; on which Mr. Chubb replied –'By G— he had seen his man do it four times.' The plaintiff then said –'They ought to be ashamed of themselves; for they had no right to touch the lock without observing the preliminaries.'

Mr Puckridge, the other plaintiff, and Mr. W. Smith, C.E., then arrived, and Mr. Charles Chubb and Goater kept calling on them to allow Goater to try to pick the lock. The plaintiffs offered to have a lock brought from the Strand and put on a door, when Goater might attempt to pick it; but that offer was declined. The lock was then wrapped up in paper, and sealed up. Goater than said –'He had fairly picked the lock, and that they would not pay him the reward, and that he was prepared to do it again, but they would not let him.'

The plaintiffs had subsequently examined the lock more closely, and found that some instruments had been used on the lock. There was also a spot of tallow grease on the inside. The plaintiffs sent the defendant a notice that they repudiated his attempt; but they were prepared to submit another lock for trial, and would attend at the Crystal Palace for that purpose on Tuesday, the 8th of August. They went to the Crystal Palace in pursuance of that notice, but neither the defendant nor Mr. Charles Chubb attended.

"Cross-examined. –He had published two editions of a pamphlet descriptive of the lock; the first edition was withdrawn

on the 14th of July. He had placed 500 copies of the second edition on the stand and in the safes which they exhibited in the Crystal Palace. He had told Mr. Deane that the conditions had not been complied with, and he said he did not know of any conditions. He had never examined the lock with a candle, and would swear positively that when it was put up in the Crystal palace the spot of grease was not on it.

"Mr. Puckridge, the other plaintiff, was then called, and corroborated his partner's account of the interview with the defendant and Mr. Charles Chubb in the Crystal Palace.

"–Tebbutt, who had charge of the plaintiff's stand in the Crystal Palace, proved that about ten o'clock one morning, about a fortnight before the 5th of August, he saw Goater and one of the firemen, named Perry, at the plaintiff's stand. After some conversation about the reward, Goater got a chair, and touched the cylinder of the lock with something like a key. He was not up a second when he got down, and said he could pick that lock in six hours, but as he was a friend of Mr. Parnell's, he would not wish the witness to mention what he had said.

"Cross-examined –The defendant had advised the plaintiffs in a friendly way to take the lock down, for the offer would surely be taken up. He should say he had not seen any of the pamphlets containing the conditions on the title page prior to the 5th of August.

"Mr. William Smith, C.E., was then called, and proved the state of the lock when it was examined in his presence, after it had been tampered with as alleged, and as to which he had given a certificate.

"Mr. William Cooper, the superintendent of the Crystal Palace, deposed that, soon after ten o'clock on the morning of the 5th of August, the defendant expressed a wish that he should go to the stand of Mr. Parnell to see him open the lock, on which the witness asked if the parties belonging to the stand would be present. He said he had sent a boy with a letter, asking them to be present, but he wished him to see him do it before they came, as he had already opened it that morning. He then showed witness the key or instrument with which he had opened it, and which he said he had made in five hours.

"The plaintiffs' foreman proved the state of the lock when it was first placed in the Crystal Palace, and the condition in

which it was on its being examined by the plaintiffs and others.

"The printer's foreman deposed that 500 copies of the second edition of the pamphlet were delivered to the plaintiffs on the first of July.

"A copy of the Morning Advertiser, containing the alleged libel which the defendant admitted he had written, was then put in evidence. It ran as follows:--[See Goater's letter, dated August 10th, at page 736]

"The Attorney-General, on behalf of the defendant, said that though he was only a workman, he might, like love, laugh at locksmiths; he would call him to prove that he had never removed the lock, or had acted in any way that was unfair; and he would also show to the jury the very simple process which he had adopted, and by which he had succeeded in opening them much vaunted lock of the plaintiffs.

"John Goater, the defendant, was then called. He said he had been for 27 hears foreman to the Messrs. Chubb. Mr. Charles Chubb was not a partner. On the 27th of July, his attention was first called to the lock in the Crystal Palace. There had previously been a smaller one there. Mr. Parnell never at any time gave him a pamphlet. He had told the plaintiff that either he or Hobbs would pick the little lock; and he replied he had nothing to fear, as Hobbs had had it in his possession for eighteen months, and failed. He never removed the lock from the plaintiff's stall. He had never removed the cover-plate, nor had he unscrewed it. The defendant then exhibited to the jury the very simple but most ingenious process which he had adopted.

He first took a small till lock manufactured by the plaintiffs, and measured the keyhole. He then obtained from a wooden model a blank key made of brass, which he blacked by means of a candle. He then inserted it, and the smut was removed in those places where each impediment met it, which portion was filed away, and the process having been repeated, a perfect key was obtained. The entire operation, including the filing of the key, occupied six minutes, and the defendant stated he cold pick four locks in the same time, but he felt nervous on the present occasion.

"Mr. Chambers suggested that this lock had not the recent improvements.

"The Attorney-General said that the defendant would pick the

same lock that he had picked at the Crystal Palace, if they got an assurance that it was in the same condition as it then was.

"The plaintiff said it was, with the exception of an alteration of one of the levers.

"Lord Campbell–That may alter the whole.

"Mr. Chambers–Whey did you alter it?

"The Plaintiff –To present it to him to pick in Tuesday, if he could. (Laughter.)

"Lord Campbell –Did you give him notice of the alteration?

"Plaintiff –We told him we would be prepared to meet him. (Laughter.)

"Lord Campbell (to defendant) – Do you undertake to pick any lock?

"Defendant –I undertake to pick any lock, it is a matter of time.

"Mr. Chambers –Can you pick your master's, Mr. Chubb's lock?

"Defendant –That is also a matter of time, but not so easily as I can Parnell's. (Laughter.)

"The defendant further stated that, on Thursday, he took the model, and on Friday he could have picked the lock but the instrument required some trifling alteration, and on the following day he opened the lock in the presence of several persons employed in the Crystal Palace. He had broken the stay to the label accidentally, and had at once given information of it to Mr. Cooper, that the officials might not be blamed.

"Cross-examined. –He had told Mr. Chubb that he intended to pick the plaintiff's lock, but he had advised him not to do so. He then said to Mr. Chubb that if he prevented his trying he would leave him. He had picked Hobbs' lock, which was wrapped all up in paper, the keyhole only being exposed. He spent five or six hours in manufacturing the instruments, at a cost not exceeding 20s. altogether. He cold not pick Chubb's lock by the same process.

“Several of the employees in the Crystal Palace were then called, and proved that they had seen the defendant open the lock. One of the witnesses stated there were only four firemen in the Crystal Palace, and they who had the entire charge of the building were on duty for twenty-four hours at a time in rotation. Some of the witnesses said they saw no pamphlets on the plaintiffs’ stand.

“Scientific evidence on the subject of the similarity of the principle in the large and smaller lock having been given,

“The Attorney-General summed up the defendant’s evidence; and

“Mr. Chambers then replied on the entire case.

“Lord Campbell, in summing up, said the question was not whether Mr. Parnell’s lock was capable of being picked or not. If they thought it could be picked, that would entitle the defendant to their verdict. He must say he thought the defendant had not acted rightly in operating on the lock clandestinely and behind the backs of the plaintiffs. Having accepted the challenge, he should have given fair notice of his intention. The fist count charged the defendant with breaking into the plaintiff’s stand in the Crystal Palace, and damaging their property; to which he pleaded leave and license. On this point the jury would say whether the defendant was at that time aware of the pamphlet containing the conditions; for, if so, he was bound to go to the plaintiff’s depot, and have the preliminaries settled, before he commenced operations on the lock. The second count charged the defendant with slandering the plaintiffs; and the third charged a written libel. They had the evidence of the plaintiff that the lock was safe until the 4th of August, when he discovered it had been tampered with by someone. The defendant pleaded that he had fairly picked the lock; and, taking all the facts into consideration, they would say whether the lock had or had not been fairly picked.

“The Jury found for the plaintiff on the first issue, as they considered the defendant had not the leave or license of the plaintiffs to enter their stand in the Crystal Palace; secondly, that the defendant had obtained wrongful possession of the lock; and thirdly, that he did not fairly pick the lock.

“Lord Campbell.–That is a verdict for the plaintiffs. Now, gentlemen, you must assess the damages.

"Mr. Chambers said he would be satisfied with such damages as would carry costs.

"The Jury then awarded damages of £10 on each count."

The following extract is from Messrs. Parnell and Puckridge's pamphlet before referred to:--

"We do confess we are elated at this result. Mr. Goater's audacious assertion, that he had fairly picked our lock, is disposed of; and we commit ourselves and our adversaries to the judgment of the PUBLIC. As to the question whether the Defiance lock is capable of being picked, our answer is, 'Let it be done.'

"In conclusion, we return our thanks to our competitors in business, who would not countenance shabby, unbecoming tricks, and were willing to give us their valuable assistance in exposing them. Fair, open rivalry in business, we rejoice to think, does not, except in some individual instances, extinguish the amenities of society, or dispense with the proprieties of trade.

"Some, perhaps, may be curious to learn what part Messrs. Chubb took with their foreman. We can only tell what we know. Mr. John Chubb attended the court the whole of the day during the trial, and assisted in conducting the defense, and Mr. Charles Chubb was present on the 5th of August, at the scene at the Crystal Palace; he was Mr. Goater's bottle-holder on the occasion; he urged him to enter our premises and take possession of our lock, and operate on it (that is, open it with a key made in the manner so properly condemned by Lord Campbell); he remonstrated violently with us before everyone present, and upbraided us for not giving Mr. Goater the premium; and he announced openly that Mr. Goater would not want money, for he could get £500 in ten minutes to carry on the war with us. Moreover, the Wolverhampton Chronicle has given up the Messrs. Chubb to us as the parties requiring the insertion of the article headed, 'Scene at the Crystal Palace,' that gave a very incorrect and highly colored account of what took palace, and which went the rounds of the provincial papers.

"Now, notwithstanding Mr. Charles Chubb's assertion as to the defendant Goater being able to pay £500 to 'carry on the war against us,' the defendant, upon being defeated, retreated, and up to the date [February 5th, 1855] of this pamphlet has not paid the costs and damages in thie action."

The last lock-picking experiment we have to notice is one that took place during the present year (1856) in America. The lock operated upon was one of Day and Newell's Parautoptic Bank Locks, described at page 470. The simple circumstance was announced in the papers, when the following particulars appeared in the Banker's Circular for June 22nd, 1856:--

"PICKING EXPERIMENTS ON HOBBS' LOCKS.– The following paragraph, copied from the Ilion Independent, having gone the round of the papers, shows that great interest is still manifested in the American lock question. An explanation of what is termed 'Mapping the Lock' may therefore not be unacceptable. But first, as to the report itself:--

"'THE HOBBS' LOCK PICKED. –The Ilion Independent asserts that the Day and Newell Lock, manufactured at New York, commonly known as the "Hobbs' Lock," has at last been picked by Lynus Yale, jun., of the adjoining village of Newport. It says –"The exact modus operandi of picking the lock of course is not expected to be made known to the public just at present; but it is sufficient to say that by a singular and ingenious method, the action of the key upon the curves and tumblers of the lock is mapped out, from which a wooden key is made, which unlocks and locks the lock, and in all respects operates on it as perfectly as the true key."'

The method of mapping the tumblers is here treated as a mystery, but any person acquainted with the mechanism of locks may understand how it is accomplished. With an instrument made for the purpose, a little printer's ink, or other suitable material, is deposited on the tumblers in such a manner that the next time the proper key is used, the ink is distributed along the edge of the tumblers at distances corresponding to the several lengths of the bits or steps of the key. The lock being thus prepared, the proper key must be used, which, of course, can be done only by the proprietor, or others possessed of it.

After this, access must again be had to the lock, and a key-bit made of wood, cut to suit the curve of the tumblers, and covered with paper, must be inserted into the keyhole. This instrument being pressed against the tumblers, takes an impression from the ink previously distributed by the proper key, and thus shows the form of key that had been just previously used in the lock. It is about a year since this method of experimenting on the American Bank Lock was first made known in

England by Mr. Hobbs. It is evidently another application of a method long since practiced to obtain a mapping of the tumblers by means of smoke, to prevent which a ring or curtain placed round the keyhole. Farther, on this new experiment being made, an additional precaution was taken by adding what are termed 'wipers' to the ring; and as this piece of mechanism both precedes and follows the key along the edge of the tumblers, it of course renders it impossible to get an impression. Such a precaution, indeed, was almost unnecessary; for though the process of mapping may be successful as an experiment, performed by leave of the proprietor, it could not, under any circumstances, be accomplished without the proper key being used in the course of the operation, as described above."

We have in the course of this work fulfilled our promise to fully explain the several modes of picking the various locks, and we have done so in the spirit of the great naturalist Reaumur, so that those who use locks should be made aware of their weak points, as well as the thieves who make such defects their constant study. We cannot teach these clever rogues more than they already know, but manufacturers may often learn a great deal which they never knew before from these professors of the locksmiths' vocation.

This leads us to notice a way of opening Chubb's combination latch, which we omitted to state when describing it (at page 417). When it was first told to us we felt amazed at the simple mode, and now state it in order that a remedy may be applied, or the use of it discontinued where real security is desired. The combined latches, or the levers which when combined form the latch, are secured when the latch is not required to act by a pin or cotter which goes right through the cap, the latches or levers, and the case. To open the latch when locked, from the outside, a hole is drilled with a centre-bit, or even a gimlet, through the front of the door over this pin-hole, and then the pin being out, a knitting-needle or any other similar instrument is then inserted into the hole of each lever in succession till it has gone through all, when by its aid the latch is lifted out of the catch and the door opened.

That the Lock Controversy has produced good effects must be admitted by all parties, even by those whose reputation as "lights" in the trade has been somewhat diminished; and if it is continued in an open, honorable, and generous spirit, further improvements will be the inevitable result.

Ignoring motos, "No friendship in trade," and "Two in trade can never agree," we would suggest that all connected with "the art and mysteries" of the locksmith's profession should act as friends and by that 'generous rivalry' consistent with such a feeling, endeavour to produce such well-constructed articles as should entitle England to be considered as the first country in the world for meritorious inventions in locks and keys. We are sorry to say that the custom is sadly too general, when one inventor or manufacturer has produced anything better than his brethren in the craft, for most of the members of the same body to unjustly criticize it and knowingly misrepresent it.

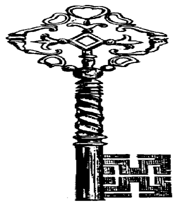
We hope, however, to see a higher principle manifested for the future, by giving to every man his due, and that others will disclaim all title to be considered as the only inventors of merit, and that they will also discontinue assuming that position in the trade which undoubtedly belongs to other, though humbler members. We do not object to one maker trying to pick another's lock, so long as it is done in a proper spirit and openly, in accordance with the term we have before used, and which fully expresses our meaning, namely, "generous rivalry." Though it may not be possible universally for "each [to] esteem other better than himself," still all who desire to be considered as honorable and respectable members of the commercial community could not lose caste by adopting such an exalted principle of action.

In closing this chapter we wish it to be particularly understood that the liability of a good lock to be picked by the professional and scientific operator and the practical thief cannot be placed on the same footing. The former understands the principle of the lock he is about to experiment upon, the peculiarity of its construction, and its weak points, and he has generally a duplicate lock (though of a different combination) of the same make and size by him, to assist him in his manipulations.

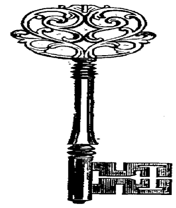
He has the opportunity of carefully preparing his instruments beforehand, and if he breaks them he can repair them and again resume the task. He operates with the assistance of the light of Heaven, and he has no qualm of conscience to make him nervous, nor the fear of detection and consequent punishment to hurry him in the performance of the feat; whilst with the thief nearly all the circumstances are the reverse, and before he has the remotest chance of picking a good lock he has first to discover who's lock it is; and there are now so many locks of the various patentees which have the keyholes of the same size, that in the absence of

the key the interior of the lock must be minutely examined before the particular make of the lock can be known.

In most cases the principal essential in effecting a robbery is TIME; and we have before had occasion to remark, that whatever contrivance necessitates more time being requisite to effect an opening into any repository, in the same degree does it add to its security, and this is especially the case with respect to the picking of a lock. Only add the slightest limb to a lock, or alter its construction in the smallest degree, and place it in the hands of the most scientific and expert operator, and tell him it is such and such a lock, and he will in vain try to pick it, though he might have picked dozens of the same lock before. Mr. Hobbs states the reason why he did not succeed in picking Cotterill's lock at Manchester to be this very circumstance, viz., that the lock was somewhat differently constructed from those locks he had before seen on the same make.[8(538)]



CHAPTER EIGHTEEN: On Keys



In most of the locks in general use, the key is the only part that is *seen,* or that has to be *handled.* In the earliest examples of metal keys great variety of form has been given to the bow or handle. The first bows were of the ring kind, as shown in Nos. 1, 2, and 3, figures **69**, **70**, and **71** respectively. Next came those of the shape of figures 72 and 73, and other similar forms.

In the sixteenth century, when lock-making had risen to such a state of perfection, the key-bows were generally elegantly decorated in patterns more or less intricate, and of artistic design in proportion to the destination of the lock to which they belonged (see figures **74** and **75**).

Whether it was for common security, or was affixed to the magnificent cabinets of the middle ages, the locks and keys of which are so elaborately worked, and as beautiful in detail as the furniture to which they were affixed, all were more or less unique in shape, forming a strong contrast to the plain and

unique in shape, forming a strong contrast to the plain and unseemly rings subsequently adopted.

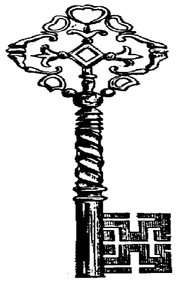


Figure 286.

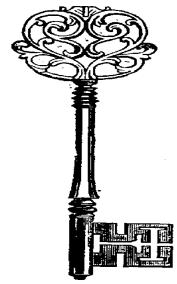

Figure 287

"One of the great reasons of the excellence of much of medieval design was that, in almost all, the manufacturer was led to take a personal pride and interest in the productions of his establishment, and frequently in the emulation excited by the admiration and approbation of his guild."

Those old trade associations did an infinite deal of good; they maintained feelings of benevolence one towards another; they led to sociality and the exercise of much charity; they assisted in rewarding the industrious apprentice and in punishing the idle; they prevented the admission of quackery and uneducated professors by regulating the qualifications to the practice of their trade; and in all these several ways tended to elevate the social position and self-respect of the tradesman as tradesman.

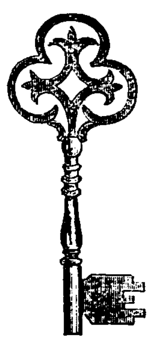

Figure 288.

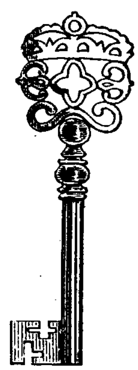

Figure 289.

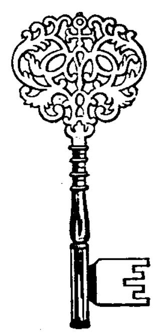

Figure 290.

Now, when too many of our manufacturers go with the hounds, shoot in Scotland, send their sons to Oxford, and teach their daughters that inanity is refinement, 'sinking the shop,' as it is called, and leaving the conduct of every part of their business (except, perhaps, the financial) to understrappers whom they despise, what chance is there that the branch of commerce they practice can receive any dignity or improvement from their connection with it?

So long as the immediate object of supplying the public demands in the most wholesale way with the cheapest things is carried out, their mission is fulfilled, and every grace beyond that point may, they consider, "'a gang tapsalteery, oh.'"

Most of the following figures have been drawn from old keys, while others have been engraved from the Art *Journal,* five from the *Illustrated Dublin Exhibition Catalogue,* and two (figures 288 and 290) are from the *Journal of Design.* We have attempted to classify them in groups, as it is thought by some that from the generic character of the designs they were produced by various members of different and distinct families.

One style of work belonged exclusively to the members of one family, whilst another style was the invariable production of the members of another family. We believe this was so, and that the "filing and finishing" of these exquisite bows were confined to a very small number of artists.

We think it more than probable that the whole of *the finest* antique bows were elaborated by *steel toy and watch chain makers,* as the only individual now in Wolverhampton, who professes to file and *finish first-class* fancy bows, is by trade a steel-toy maker; and his father and grandfather were also in the same business.

The expression "filing and finishing," must be understood to include the entire elaboration of the bow, which consists of first drilling the perforations, and then finishing as desired with very fine small files and a graver. The key is then "casehardened" by the usual process, and is hence called a steel key.

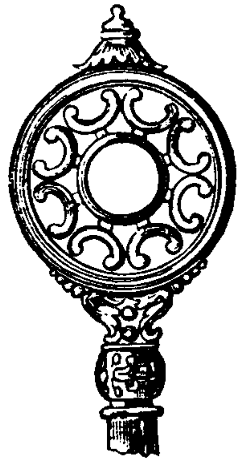

Figure 290A.

Some of the modern fancy bows are produced from *dies by* the stamping press. Figure 290 represents a bow of this description.

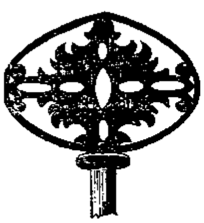

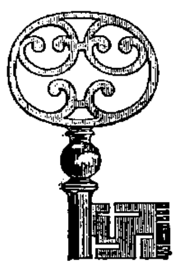

Fig. 338 Fig. 339 Fig. 340 Fig. 341 Fig. 342

Figures 286, 287, 289, 340, 343, and 344 are from the originals at Marlborough House. We are of opinion that these, together with the whole of the preceding specimens (with two or three exceptions) are of English workmanship of the sixteenth and seventeenth centuries. Figure 343 was originally brought from Penshurst.

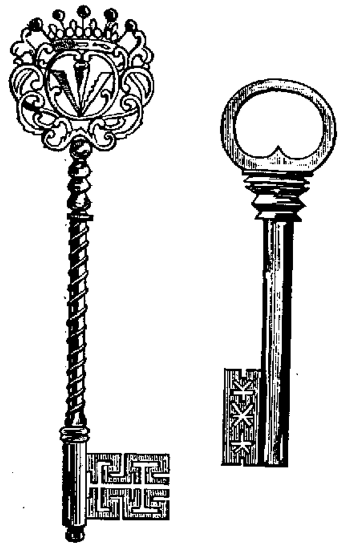

Figure 343. **Figure 344.**

Figures 345, which is drawn half the size of the original, represents a noble outer-door key, that belonged to the old Town Hall of Wolverhampton.

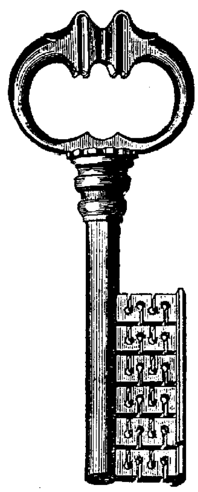

Figure 345

The bow, although of a bold character, corresponding with the office of the key, is not inelegant in form. The particular construction of the lock it belonged to is unknown; but we are of opinion that all the locks containing such intricate and numerous wards were constructed similar to the spring locks of the present day, in which the key *does not* perform *a* revolution.

On no other hypothesis could such wards be placed in the lock;

and that all the wards represented in the keys of these antique locks were really contained in the locks is evident from the specimens in the collection at Marlborough House.

Figures 291 to 299 inclusive and figures 301 represent fancy bows of a very early date, and serve to mark the period when the ordinary ring was changing to a shape of an ornamental character. The same idea appears to have suggested the whole of the examples in this group.

Figures 302, 304, 305, 306, 307, 308, 309, 316, 317, 318, 321, 323, 329, 332, and 339, are all of a similar character, being composed of scrolls, curves, circles, and lines, and show what pleasing designs may be obtained by a tasteful combination of such simple figures.

Figures 312, 318, and 323 represent modern bows, which have a very pleasing appearance, and are the design and workmanship of Mr. Henry Yates, lock manufacturer, Wolverhampton.

Figures 333 to 338 and 342 are unquestionably the production of one individual. The figures are ingeniously introduced into them, and stamp them with a character peculiar to themselves. The freedom of these designs prove it was no ordinary artist that "filed them out." The whole of them, with most of the previous and following specimens, may be studied with advantage.

Figure 344 represents a key with a bow very plain and simple, yet exhibiting artistic feeling in the design.

Figures 354 is a good specimen of a foliated bow; the scrolls are tastefully introduced and agreeably disposed.

Figures 356 is another bow with foliage introduced, and is very pretty. Figures 341 is unique.

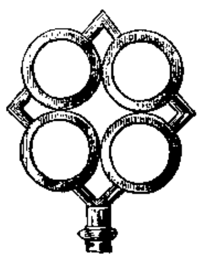
As plain examples notice seven figures, 300, 313, 319, 324, 326, 327, and 330, which are formed of three elliptical curves, than which nothing could be more simple.

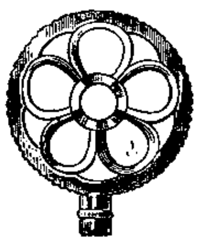
Figures 328 is the only example of its style, as besides its beautiful form, the scrolls are chased.

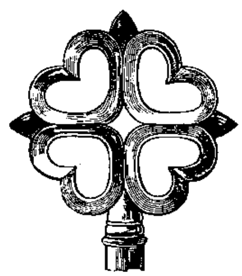
Figures 315 and 331, composed of scrolls and ornament, have the appearance of net work, a style peculiar to the bows of the seventeenth century. The center of each of these examples, as

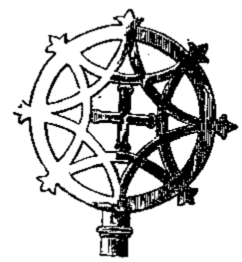
will be observed, partakes of the form of the cross; and this was a very common ornament at the time in question. The same characteristic is observable in the bows represented by figures 310, 311, 314, 320, 322, and 325.

Figures 351 is a beautiful design from Feuchere, but it is too elongated and is more suited for a *whip* handle than the bow of a key, which should always have a considerable breadth *across* the bow.









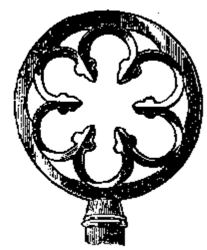


Fig. 346 Fig. 347 Fig. 348 Fig. 349 Fig. 350

Figures 346 to 350, which are of Gothic design, formed part of Messrs. Chubb's collection exhibited at the Great Exhibition of 1851. Messrs. Chubb and Son have devoted much attention to the improving of key-bows which may be described as restorations, for by taking the best antique models, they have in some instances improved upon them, and have thus substituted forms of much elegance for the ungainly shapes of later times.

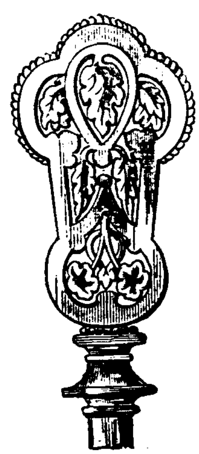

Figure 351.

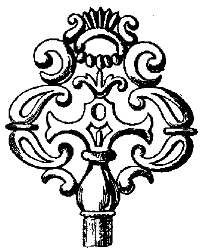
Figures 353, 356, 357, 358 and 359, without explanation, would be supposed to represent the handles of *keys,* but we think it only

right to mention that they represent *skewer* handles, as manufactured by Mr. Penny, London, in electroplated metal. We were so struck with the beauty of the designs and their applicability to the more refined and honorable office of key-handles, that we could not refrain from copying them from that truly admirable and art-instructive work, *The Art Journal.*



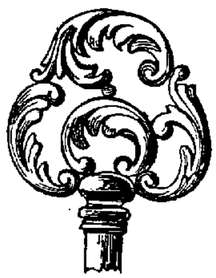


Fig. 352

Fig. 353

Fig. 354

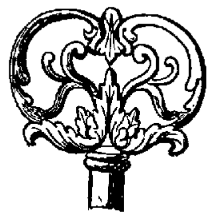

Fig. 355

Fig. 356

Fig. 457

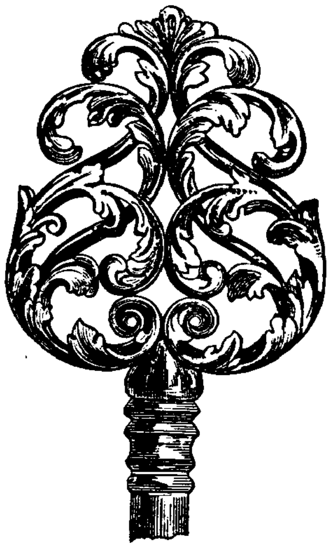

Fig. 358

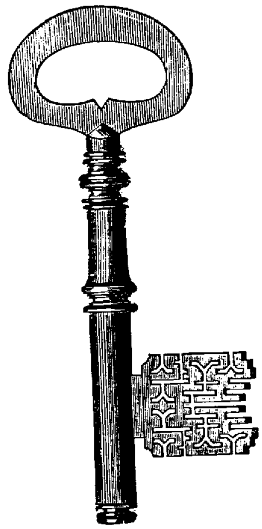

Fig. 359

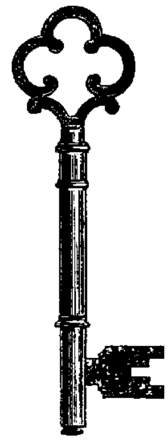
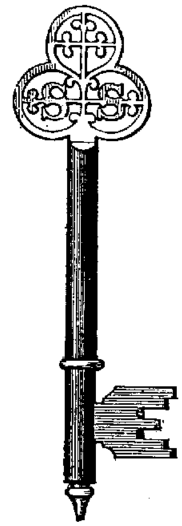
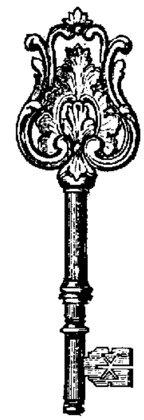


Figures 352 represents a bow more massive than most of the preceding examples in the same class. It appears to have been a favorite design two centuries ago.



Figures 360 represents the bow of a chamberlain's key of office, and is an elegant example of *gilded German work.* The foliated ornament forming the bow is most skillfully disposed. The original key is at Marlborough House.



From these beautiful specimens of the sixteenth century, the bow gradually degenerated in design until it again assumed its primitive form, the common ring, when within the last few years, and more especially since the Great Exhibition of 1851, considerable advances have been made towards attaining the same perfection in the design and workmanship of fancy key-bows as prevailed several centuries ago.

Fig. 360

Fig. 361

Fig. 362

Fig. 363

Fig. 364

Figures 361 represents a noble key drawn half the size, belonging to a lock with most intricate wards, manufactured by Mr. James Gibbons, jr. of Wolverhampton, but we think the bow might have been much improved.

Figures 362, 363, and 364 are by the same maker. Figures 364 represents a key with a beautifully embossed bow in or-molu. All these belong to *two-sided* locks.

We had wished to have given more examples of these art specimens of the lock trade, but our space forbids. We had intended to have given also a few examples of ornamental locks besides the one which is by Mr. James Gibbons, jr. of Wolverhampton, but the same cause prevents us. The specimen referred to is a very creditable and beautifully executed piece of work in *blued-steel.*

Mr. F. W. Fairholt, in a communication to the *Art Union* of March, 1846, on "The Industrial Arts in Paris," makes the following remarks on the subject of "key-handles:"

"In the present day, our characteristic utilitarianism has bestowed the greatest possible attention on the wards of the lock, and that part of the key which opens it, to the nearly total neglect of the handle. It would be folly to quarrel with such an arrangement, because the principal object is considered; but it is not, therefore, to be denied that an extra trifle in outlay should not be bestowed on the key-handles, more

particularly as they are often left in the locks; and, as in most instances they are too small to admit the hand in turning them therein, the more reason is there that the oval space be filled with some ornament which should please the eye, and would really at the same time afford a firmer and better hold in turning than the open band of steel now so universal.”

"If the cost of the work be objected to, or any elaboration of design scouted as unnecessary, this, after all, will not defend the thoughtless monotony of our ordinary key-handles, because designs as simple might be found, still exhibiting artistic feeling and some taste in construction.”

"I should, however, imagine that a little extra outlay would be well laid out by the manufacturer in this one branch of our trade, for people will generally buy what is good; and certainly nothing in the way of elegant improvement is made in vain in England. The public generally appreciate and purchase such things in preference to others of less excellence. And surely we are not less likely than our ancestors were to secure for our best cabinets and choicest cases articles combining utility and tastefulness at the same time."

After giving numerous examples of antique key-bows, several of which we have copied in the preceding pages, he says,

"I close a subject that would admit of many more examples being given; my object has been merely to show that as the handle of an ordinary key does not admit the hand, it would really be a more serviceable thing if filled with ornament, which would give a firmer hold in turning it, and render an article of utility also one of ornament, and this at an outlay that would well repay itself.”

“It is surely worth while in these days of improvement to look well to all these things, as the public eye is open to their appreciation; and now a reaction is taking place, and the enriched style of internal decoration in use by our ancestors is being so much adopted by ourselves, it would be worth the attention of the manufacturer to supply the market with characteristic accessories."

We quite agree with the above remarks, and it will doubtless as much surprise Mr. Fairholt as our readers generally to be told that even were the public willing to pay for ornamental bows to their keys, there are no artists now in the trade who could

elaborate such specimens as shown in figures 74 and 75, and other inimitable specimens which may be seen at Marlborough House.

It is supposed that the ornamental parts in these bows were cut out with a *graver,* and afterwards finished with very fine files. We are of opinion that the keys represented were originals, and that few if any duplicates were made of these or others in the same class. The value of such specimens at the period of their production must have been from ten to twenty guineas each.

It must be understood, as before stated, that the filing of fancy bows is a trade quite distinct from either lock making or key-making; it is of a more artistic character. We must remark that most of the elegant bows exhibited by some makers and so full of work are genuine *antique* specimens soldered on to *modern* stems.

As it may interest some of our readers to know the cost of these ornamental keys, we here give the following table, showing the value of some of the bows before referred to. To these charges respectively must be added the cost of making the key:—

We lately discovered Richard Manning,a working key-maker, who

informed us that his father used to make fluted stems to keys more than sixty years ago, by the following process: A hole was first drilled up the stem of the blank key; a *mandrel* of the grooved triangular shape as represented in the cut (figures 76) was next driven up the hole and made to fit quite tight; the key containing the mandrel was then heated, and the stem hammered until the required shape was formed when, after cooling, it was finished by filing in the usual way.

Until lately, if a large door had to be secured by a lock, it was thought that it needs be a *large* one with a corresponding *large key.* This was universally the custom until the plan was adopted of throwing numerous bolts by a knob or handle, as described earlier, and securing these large bolts by a small lock and key. In the former instance, the keys were too large to be carried about the person, except by attaching them to the girdle, or to a chain worn around the neck.

As the convenience of small keys is becoming appreciated more and more every day, we may remark that the key, figures 361, which is drawn full size, is sufficiently large and strong enough to secure any door, however massive; and being so small, it may be kept on the key-ring in the pocket. Besides the convenience of a key so small, the lock is more secure, as it is always more difficult to pick or tamper with a small lock than with a large one.

The smallness of the keys of the locks exhibited by Messrs. Bramah and by Messrs. Chubb at the Great Exhibition of 1851, in comparison with the "ponderous and bulky" key belonging to Day and Newell's American bank lock, appears to have made a deep impression on the minds of the Jury, as it is almost the only point upon which they venture to give an opinion.

The use and advantages of *master* keys are very imperfectly understood and appreciated, otherwise the principle would be more generally adopted. How convenient and pleasant if you have fifty doors of various kinds, whether to rooms or articles of furniture, etc., to carry on your key-ring but three or four small keys, and yet every one of the locks to be different and incapable of being locked or unlocked by each others' keys.

We have in previous chapters treated on the subject of *suite* locks and master keys, and it is upon this principle that the locks are fitted to the various prisons. According to Mr. John Chubb, "two hundred and twenty locks *might* be made with one

keyhole, and a separate key to each, yet having one master key for the whole; but if a greater number was required, it would be necessary to have *two* keyholes."

Mr. Duce, jr. can make a suite of locks, each lock to differ, with master keys to pass the whole, and with but *one* keyhole to each lock, amounting to 1,100.

From the following passage in Dr. Plot's History of Staffordshire, it appears that the locksmiths of Wolverhampton were in the seventeenth century then celebrated for constructing locks in suites:

"But the greatest excellency of the *blacksmiths* profession, that I could hear of in this *county,* lies in their making *locks* for doors, wherein the *artisans* of *Wolverhampton* seem to be preferred to all others, where they make them in *sutes, six,* eight, or more in a *sute,* according as the *Chapman* bespeaks them; whereof the *keys* shall neither of them open each others lock, yet one *master key* shall open them all; so that these *lochs* being set upon the doors of a house, and the *inferior keys* kept by distinct *servants,* though neither of them can come at each others *charge,* yet the *master* can come at them all."

"Beside the *master* turning his key in any of the *servants* locks but once extraordinary, the *servants* themselves cannot come at their *charge,* neither shall the *servant* spoil his key or the lock in endeavoring it; for his, after the *master key* has given the lock a second turn, will only run round in it backward and forward, without either stopping at, or prejudicing it anything."

"Nay so curious are they in *lockwork* (indeed beyond all preference) that they can contrive a *lock, so* that the *master* or *mistress* of a family sending a *servant* into their *closets,* either with the *master key,* or (if they permit an *inferior key)* with their own, can certainly tell by the *lock* how many times that *servant* has been in, at any distance of time; or how many times the *lock* has been shot for a whole year together; some of them being made to show it 300, 500, or 1,000 times."

"Nay one of the chief *workmen* of the *town* told me (might he have *workman's wages)* he could make one should it to 10,000 times. Farther yet I was told of a very very fine *lock* made in this *town,* sold for 20 pounds, that had a set of *chimes* in it that would go at any hour the *owner* should think fit. And these

locks they make either with *brass* or *iron* boxes so curiously polished and the keys so finely wrought, that 'tis not reasonable to think they were ever exceeded, unless by *Tubal Cain,* the inspired *artificer in* brass and iron."

We have frequently in the course of this work spoken of the combinations that could be produced in some locks. The number of possible changes or *combinations is* found by multiplying the terms 1, 2, 3, 4, 5, continually into each other. Thus 1 x 2=2; 2 x 3=6; 6 x 4=24 24 x 5=120.

The changes that can be rung on twelve bells amount to 479,001,600, which is identical with the number of combinations which can be produced in a lock with twelve tumblers or levers. The twenty-four letters of the alphabet admit of 62,044, 840,173, 323,943, 936,000. So does a lock that comprises twenty-four pieces, which admit of the requisite variations in size or shape. Therefore to open a lock by "ringing the changes" would require either a number of keys equal to the number of combinations the lock is capable of, or a key which can be altered to an equal number of permutations.

It is true the very first might be the right one, and it is as equally likely that the lock would not answer to any but the last.

To illustrate the above principle of *combinations,* we will relate an anecdote. A person wishing to dine every day with a small family, happened to drop in when the family comprised six persons besides himself. He asked mine host the amount he should pay him to take up his abode in the house as long as he could place the six members of the family and himself in a different position at the dinner table every day. Mine host thinking it would not be long, named a trifling sum. "Oh, I am quite satisfied," replied the stranger," for I shall now have to sojourn with you for 5,040 days!"

Figures 365, which represents a key with four steps besides the terminal step, is the key of a four-lever lock. The following table shows how the twenty-four changes are produced by the four steps of the key. We will start with the arrangement of the steps as shown, in the cut and numbered 1, 2, 3, and 4 respectively.

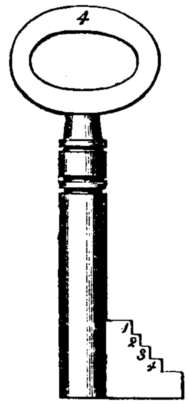

Figure 365.

Now the second combination is produced by simply placing the step No. 3 in the place of the step No. 4, and *vice versa;* and the whole number of the twenty combinations are effected by the simple transposition of which answer to the four steps the four figures, of the key:

SERIES OF 24 CHANGES, FOUR LEVERS IN EACH LOCK					
1st	combination	1234	13th	combination	3124

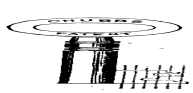
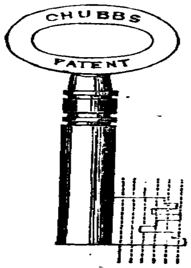
60	"	32541	120	"	54321

On reference to Mr. Parsons' table, the number of the various combinations which may be produced by the different numbers of levers in a lock will be seen at one view. An idea of the immense number which can be made may be formed from the fact that to work out the changes in a lock with 12 levers, and make 10 changes a minute, would require 91 years, 3 weeks, 6 days, and 6 hours to exhaust the variations.

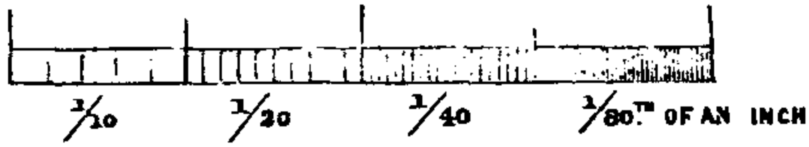
To explain the theory of "working the changes," we will take only seven figures: l, 2, 3, 4, 5, 6, 7.



1	2	3	4	5	6	7
3	4	5	6	7	1	2
5	6	7	1	2	3	4
7	1	2	3	4	5	6
2	3	4	5	6	7	1
4	5	6	7	1	2	3
6	7	1	2	3	4	5



The seven figures are placed in the first horizontal rank in their numerical order. The second rank (the next below the top or first rank) may either commence with 2, 4, 5, or 6, but in our example it begins with 3; the third rank, therefore, must begin with 5, the fourth with 7, the fifth with 2, the sixth with 4, and the seventh with 6.



The commencement of the seven ranks being thus determined, the other numbers, as observed, must be written down in the order in which they stand in the first rank, going on to 5, 6, and 7, and returning to 1, 2, etc., until every number in the first rank be found in *every rank* underneath, according to the order chosen at the commencement.

From this arrangement it will be evident that no number can be repeated twice in the same rank, and consequently the seven numbers 1, 2, 3, 4, 5, 6, and 7 being in each rank must of necessity make the same sum.

Mr. Chubb, in his paper before referred to, states that 2,592,000 changes may be effected on the key (figure 367) of a three-inch drawer lock; and we have also heard of locks being made with a variation between their separate combination parts of only one-millionth part of an inch; but all such statements must be considered as figures of speech, and not as facts, as from an examination of the following scale it will be apparent that such niceties in practice are utterly impossible.

CHUBBS
PATENT

1/10
1/20
1/40
1/80TH OF AN INCH

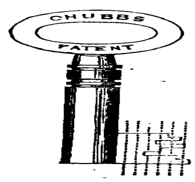


Figure 367. Chubb's Key to a 3-inch drawer lock.

Figure 368-Scale of parts of an inch

Figure 368 represents a scale of 10, 20, 40, and 80 parts to an inch, showing how moderate even the tenth part of an inch is, and that the 80th part can only just be indicated by the graver on the wood block. We do not deny that the above number of changes can be effected on a key sufficiently large to admit of the requisite variations, but we distinctly say that it is impracticable with the key of a three-inch drawer lock, or even with that of a ten-inch rim lock.

The bit of the key represented by figures 367 measures 13/40" from its junction with the stem to the extreme point of the longest step; and the shortest step measures 5/40".

Now it must be borne in mind that whenever a series of combinations is required different from those effected by the transposition of the various keysteps forming the bit, it must be done by *shortening the length of the steps,* but (and this must be particularly noticed) all the steps must be reduced in the same ratio, consequently the key of a three-inch drawer lock to be capable of being reduced, as Mr. Chubb says, twenty times, thereby giving 14,400 combinations, would require the bit to be at least one inch longer than that of the key shown in figures 367.

The shortest step must always be cut at least a sixteenth of an inch from the stem, and the lever which that step is intended to work would remain "dead," or in a quiescent state, i.*e*., both it and the key would cease to be levers in action, as the bit in revolving would merely pass that particular lever without lifting it at all.

On reference to the scale (figure 368), it will be apparent that instead of the step in question being capable of twenty reductions, allowing each reduction to consist of not more than the 40th part of an inch, two reductions would be the most that could possibly be effected, the *extreme* length of the shortest step being but 5/40".

But we go further, and say that these additional combinations cannot be made for practical purposes by reducing the steps as

above described with a variation *less* than the *twentieth* of an inch, and therefore that such a key could only be reduced throughout the six steps it contains once, which with the 720 combinations effected by the transposition of the steps, as shown in the cut, would give 1,440 as the total number of changes such a key is practically capable of with safety.

A few more changes, however, can be made by cutting the deep step right to the shank, and of course all the others in the same proportion; but this is very objectionable, as it separates the bit into two parts, and thus makes it very liable to be broken.

If a lock is *gated so* closely at first that there is no play allowed for the levers, in a very short time the wear of the key, as well as the wear of the combination parts of the lock which come in contact with the *nose* of the key-bit, is quite sufficient to prevent the lock answering to its key. On this account it is the custom with some in the trade, who have given this point due consideration, to leave the gatings of the levers a little wider in the back part to compensate for such wear, otherwise the levers would drop, and so prevent the stump of the bolt from passing through the gating from one rack to the other in locking or unlocking, or the stump would be *dragged* through the main-gating.

For the same reason, it is customary to bevel a little to the side of the stump which enters the main-gating in the act of locking, or to make the end of the main-gating next to the to center of motion a little wider than the other end.

Although the keys are *hardened* after being cut and finished, which makes them of course much harder than the brass of which the levers are made, yet it is the fact that the hard iron key-bit wears considerably more than the soft brass levers; therefore to talk of such close fitting is simply absurd. Like many other theories, it may *appear* feasible, but it is never carried out in practice.

It is found when two keys are stepped to the same lock, with a variation of the 40th part of an inch between the steps on the one key and the steps on the other, that both keys will work the lock. So much for the *theory* of combinations, and now for the manner of properly effecting them in locks.

To carry out the principle of having every lock different requires more care than is usually given to the subject, for

unless a proper system is adopted and a register kept, the same combination is sure to be frequently cut over and over again in the key-bit.

There are two ways of cutting the steps of the key-bit: one by a machine, the other by hand. Those who cut by a machine with reasonable care cannot go wrong, that is, they will not cut a duplicate key unless so required, while with those who cut by hand the same combinations are weekly cut over again.

In some shops different workmen, who have been stepping keys as they thought quite different from each other, have found that the keys passed each others' locks. The men from use, get a certain combination in their minds, which is frequently repeated in the key.

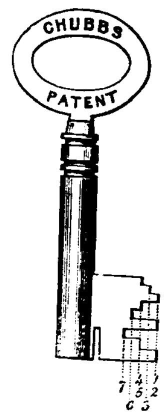

Figure 369 Key to a Chubb's 7-lever Detector Lock

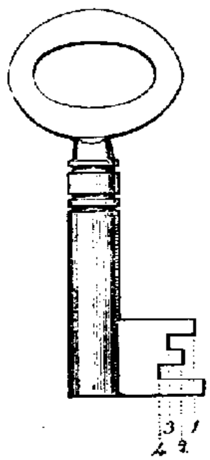
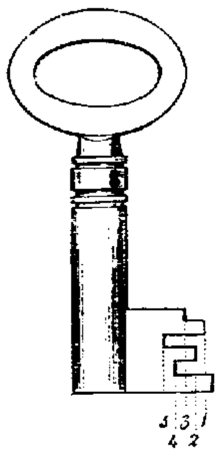
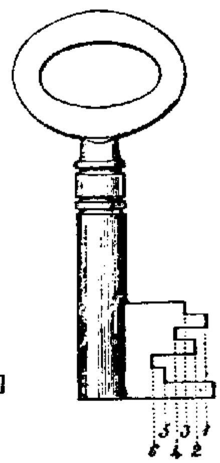
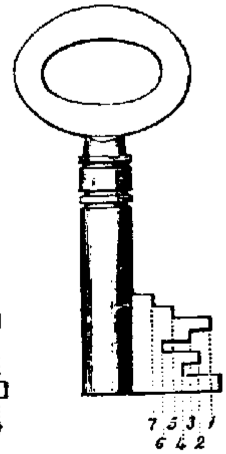
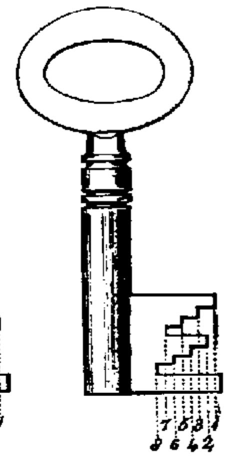
Another serious objection to cutting keys by hand is that two steps in the same key are often cut of the same length, as shown in figures 369, thereby lessening the security of the lock; for, as before shown, if the key-bit has seven steps and corresponding levers in the lock, there are 5,040 combinations; whereas, if two of the steps are alike: that is, of the same length, it would only be equal to a lock with six levers, having 720 combinations; and if two others in the same key were also alike, it would then be only equal to a key with five steps, having only 120 combinations.











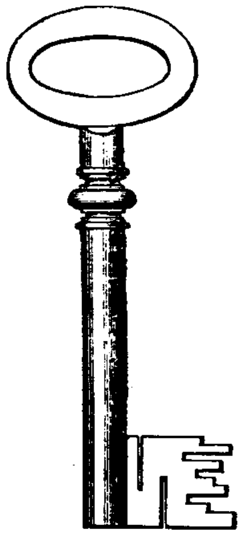


Fig. 370 Fig. 371 Fig. 372 Fig. 373 Fig. 374

The above cut represents a series of five keys stepped respectively for locks with 4, 5, 6, 7, and 8 levers. It will be noticed that in each key, no two of the steps are of the same length, thereby insuring the number of combinations each lock admits of, viz.,

4 levers = 24;
5 levers = 120;
6 levers = 720;
7 levers = 5,040;
8 levers = 40,320 respectively.

Keys with wards and guards cut in the bit, as shown in figures 375 and 376, although they may have the requisite number of steps, can never have produced in the locks to which they respectively belong, the number of combinations they are otherwise capable of, as the *deep* steps cannot be cut in the bit. To effect the true number would require the deep step to go right through the ward.

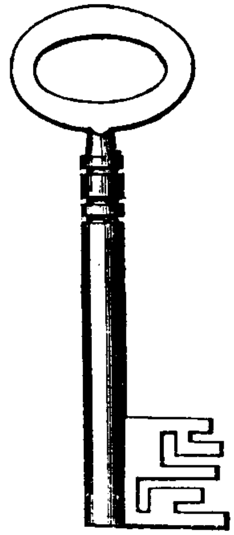

Figure 375 Figure 376

Before closing this chapter, we must notice a great defect in the construction of some makers' keys. A key to a lock with seven levers has eight steps on its bit: seven for the seven levers, and the eighth or bottom step to throw the bolt; and for locks which contain a curtain there is another step at the top, making altogether nine, as shown in figures **369**.

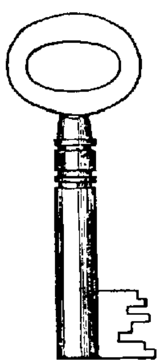

Figure 377 Weak terminal step

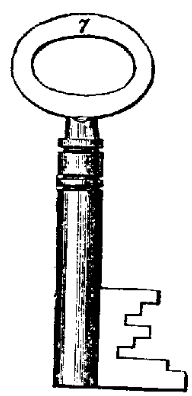

Figure 378 Strong terminal step

Now upon a moment's reflection it will be apparent that the work required from the bottom or terminal step and the others is very different, the seven steps having merely to lift the levers to their positions, while the bottom step by coming in contact with the talon of the bolt has to move it backwards and forwards in locking and unlocking, the bolt being much heavier than the levers, and its thickness about double that of one of the levers.

For these reasons, the step which moves the bolt should always be double the thickness of one of the other steps, or even more. Figures 377 and 378 will show more clearly what we mean. There is another important reason why the bottom step of a key-bit should be particularly strong, and that is that when a key is dropped upon a hard substance, as a stone or brick floor, and it happens to fall on the bottomor terminal step, it is almost certain to break the end off.

With one maker's locks, some of which we have used, from this cause we have often had keys returned to us with just the point broken off the bottom step, and have had to supply new ones. In some cases the piece had broken in the lock.

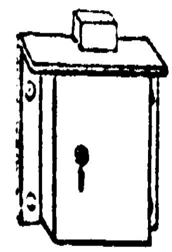
Another defect in some makers' keys is that the *nose* of the bit is *too pointed,* as shown in figures 379, which causes the key to wear itself and the levers to a more considerable extent than is the case when the bit is shaped as shown in figures 380, in which the *angles* are only *just* taken off.

Fig. 379   Fig. 380

CHAPTER NINETEEN: The Various kind of Locks and their Comparative Prices

The various kinds of locks may be divided into the following classes, viz.:

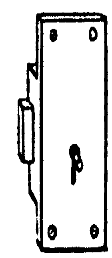
1.—Brass cabinet and other best locks.



2.—Bright and japanned iron cabinet and other common locks.
3.—Stock or wooden-case locks.

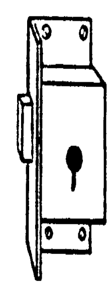
Each class contains many varieties, and there are numerous sizes of most of the kinds, and also several qualities of many of them.

We will first describe the different kinds, and then show in a tabular form their various sizes and prices.



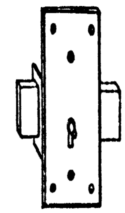
CLASS I. BRASS CABINET AND OTHER BEST LOCKS. This class comprises the following kinds, which are principally manufactured in Wolverhampton:

***Till or drawer* locks**, as represented by figure 381, are used in very large quantities, and are made of various qualities. This figure represents a *cut* till, which is the kind more generally used, but some are also made as the *straight* cupboard (figure 382), and are often used for the drawers of common iron safes. They are also made as *spring* locks, i.e., the lock locks itself by closing the drawer.



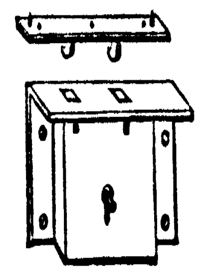
Figure

***Straight cupboard* locks** (figure 382) are constructed for screwing on to the door in the readiest manner, with the flat side against the woodwork, thus causing the whole of the lock to project from the surface of the door. They are made both for right or left-hand doors, as required.



Figure

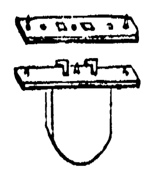
Cut cupboard locks (figure 383) are the same as the latter, except that a cavity has to be sunk in the door for the case and plate of the lock to occupy, so that the back-plate of the lock is flush with the surface of the door. Both these kinds can be made as spring locks if desired.



Figure

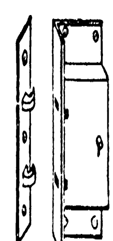
Double-handed straight cupboard **locks** (figure 384) are so constructed as to do for either a right or a left-hand door.

Figure



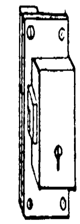
Box and sloping desk **locks** (figure 385) are both made with a link-plate, which is secured to the lid with two or three screws. For a desk which slopes the selvage of the lock-plate is made to slope accordingly. These and all other *link plate* locks, when affixed to wooden articles of furniture, afford no security against violence, as a very small lever or a turnscrew is sufficiently powerful to prize the lid open by drawing the screws out of the woodwork.

Figure



Iron chest locks are of this description, but are made much stronger. *Cash box* locks also are similar, but have generally a nozzle, and the linkplate instead of being made to be fixed with screws, is made so as to be soldered only.

Mortise camp desk **locks.** (Figure 386) These locks have a plate which is screwed to the lid of the desk, as in the last named, but the plate is *without* links. Holes are sunk in the lid where the plate is affixed to allow the bolt to enter and fasten.



Figure

Pedestal or sideboard **locks.** (Figure 387) These locks are used for the pedestals of sideboards. They are similar to a box lock, but with the keyhole at right angles to the position of the keyhole in a box lock.

Figur

Link-plate cupboard locks *(figure* 388) are made so that the link-plate is fixed to the side of the cupboard at right angles to the bolt and face of the lock. They are used for the wings of wardrobes. They require very careful fitting to make the door and lock work pleasantly. Chamfering the link would be an improvement. The lock is of course let into the door, and made for right or left-hand as required.

Figur

***Traveling desk* locks.** (Figure 389) These are used (as their name implies) for portable or traveling desks and cases.

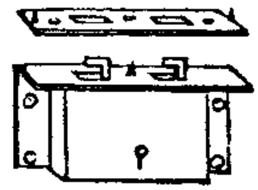


Figure 389

***Mortise box* locks** (figure 390) are of the same construction as figure 385 except that these are of the mortise shape.

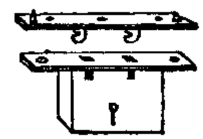

Figure 390

***Flush-bolt mortise traveling desk and pianoforte* locks.** (Figure 391.) These are similar to the locks (figure 386) described before, except that the bolt in these locks remains flush with the selvage of the lock-plate when the lock is unlocked.

Padlocks. (Figure 392) These, as is so well known, are used for carpet and leather bags, and for all other purposes where hasps and staples or chains are affixed to the articles or depositories to be secured.

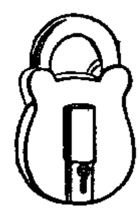

Figure 392

Puzzle or letter locks. *(List* No. 4) These are generally used for carpet and leather bags, and other similar purposes for which the

carpet and leather bags, and other similar purposes for which the ordinary padlock is applicable.

***Portfolio and writing case* locks.** (Figures 393 and 394) These are made either of the form of figure 393, or with a nozzle which projects from the face of the lock, as in figure 394. They are secured to the above-named articles with rivets.

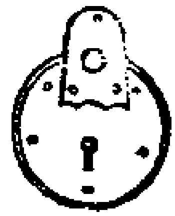

Figure 393

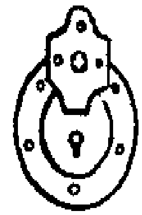

Figure 3

***Trunk and portmanteau* locks** (figure 395) afford no security against violence, the whole of the lock being fixed outside the article it is intended to secure with screws or rivets.

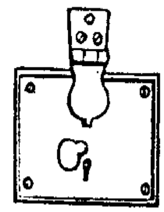

Figure 39

Book-edge or ledger locks. (Figure 396) These are made with a spring-bolt to lock itself on the book being closed.

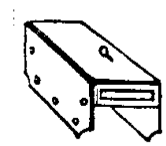

Figure 39

***Carpet bag* locks.** (Figure 397) These are constructed so as to be secured by rivets to the iron frame of carpet and leather bags.

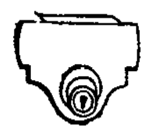

Figure 39

***Letter bag* locks** (figure 398) are precisely of the same construction as the trunk locks (figure 395), but of a smaller size.

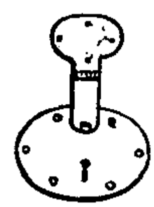

Figure 398

***Escutcheon* locks.** (Figure 399) These are used for securing the keyholes of iron safes, &c., from the prying curiosity of children and servants. (See pages 56 and 322)

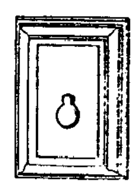

Figure 39

All the preceding locks are made of brass.

Combination **latches** (figure 400) are constructed with a number of separate latches, as described before, which when combined form the latch. They are principally used for street doors.

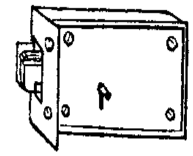

Figure 40

Flush night **latch.** (Figure 401) This is let into the door, and is therefore *flush* with the surface of the woodwork.

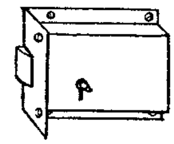

Figure 401

Rim night **latch.** (Figure 402) This is made to screw *on* to the door, and consequently it p*rojects* from the surface of the door as all rim locks and latches do.

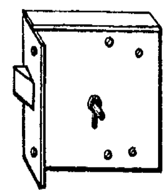

Figure 40

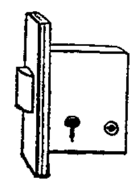
Mortise night **latch.** (Figure 403) This is the same as the two former latches, except that it is mortised into the thickness of the door.



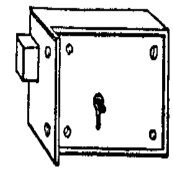


Figure 403

All these (figures 401, 402, and 403) are made to open on the *inside* by drawing back the knob, and on the outside with the key only. They are usually made to spring only, but can, if required, be made to lock as well. There is also a small vertical slide that fits into the bolt, which either fastens the bolt back altogether, or when the bolt is shot out secures it so that the latch cannot then be opened with the key from the outside. They are usually fitted with small keys, and are much used as night latches for street doors, having superseded the use of the insecure *French* latch.

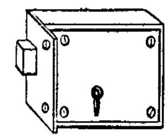
Rim dead lock, to lock on one side only. (Figure 403) This is

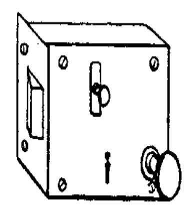
Rim dead lock, to lock on one side only. (Figure 403) This is constructed with one bolt, which can only be shot out and in by the key—hence called a dead lock.

Rim dead lock, to lock on both sides. (Figure 404) This lock is constructed in the same manner as the latter, except that it locks and unlocks from *both* sides of the door to which it maybe affixed.

Figure

Spring rim or drawback locks for front doors. (Figure 405) These are constructed with but one bolt, to lock and spring by the key, and to draw back by the knob on the inside. They are principally used for the front doors of dwelling-house, and may be described as extra large and extra strong night latches.





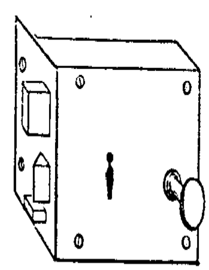


Figure 4(

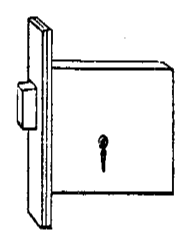
***Three-bolt rim* locks** (figure 406) are constructed with a spring latch-bolt, which is worked by the knob, a main-bolt, which is worked by the key, and a private bolt, which is worked by a slide fixed to the under-side of the rim when the lock is fixed. This and figures 400, 401, 402, 404, 405, 406 and 407 have the cases made of iron japanned black, but with brass bolt-plates or striking-plates, whichever the locks require, and with other best furniture.



Figure

Formerly *rim* locks were used for the doors of parlours and even drawing rooms, but their unsightly appearance soon caused the substitution of the *brass-cased* locks, which in their turn were superseded by the *mortise* lock, the inventor of which useful and elegant improvement we have failed to discover.

Figure

***Mortise one-bolt dead* locks.** (Figure 408) These are used for the same purposes as the lock figure 405, but in addition are sometimes used as extra locks for the doors of dwelling-houses, &c. This and the two following varieties are *two-sided* locks. It must be particularly noticed that all two-sided locks are not so secure as one-sided ones the number of the levers in each case being equal.

Figure

A *one-sided* lock with five levers is about ten times more secure against being picked than a two-*sided* lock with the same number of levers, as by referring to figures 288, 290, 302, and 304 (pages 758 and 780), it will be seen that the steps in the upper half of the key-bit are precisely the same as those on the lower half; the deep step being in the middle, and dividing the bit into two equal parts.

***Mortise two-bolt* locks.** (Figure 409) These are constructed with a spring latch-bolt, which is withdrawn by the knob; and also one bolt, which is shot out and in by the key. These locks are used for chamber and other room doors.

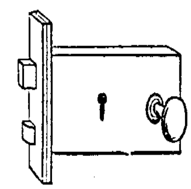


Figure 40

***Mortise three-bolt* locks.** (Figure 410) These are the same as the last described, but with the addition of a private bolt, which can be worked from the *inside* of the room only by turning a small knob; and this bolt secures the door against its being opened from the outside, thereby dispensing with the use of the *main-bolt,* which is moved by the key.

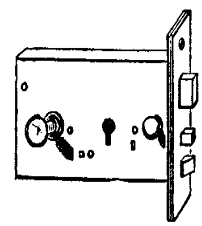

Figure 41

***Mortise drawback or spring* locks.** (Figure 411) These are constructed with but one spring-bolt, but which can be withdrawn by the knob, and locked *out further* by the key; in the latter case, the bolt can only be withdrawn or unlocked by the key.

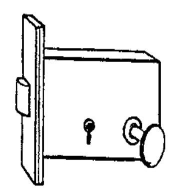

Figure 41

Besides the locks before described, there are many other kinds, as gate locks, alcove locks, "box of wards," which used to be employed for securing the doors of iron safes (see figures **4, 23** and **236**), and "iron door locks, with projecting bit," some of which are also now *used* for the same purpose as the "box of wards." (See b, figure 36). Also spring book-case or wardrobe locks, which are constructed with a knob, and are similar in all respects to the two-bolt mortise lock, figure **409**, but considerably less in size.

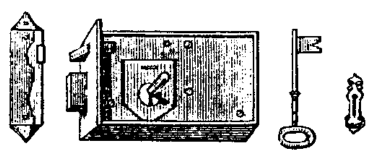
There is also another lock used for front doors, called a two-bolt knob or drawback; it contains two *spring bolts,* both of which must be released before the door can be opened. One of these bolts is acted upon by turning the knob, as in an ordinary

rim lock; the other by pulling the knob back, as in a drawback lock. The key releases the drawback bolt from the outside, and also locks it, as in the *ordinary drawback* lock. It is, in fact, a rim lock and drawback lock combined.

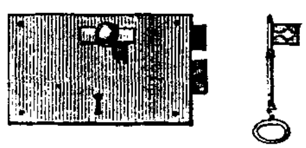
From the preceding description of the various kinds of locks it will be seen that rim locks are those which project from the surface of the doors to which they are attached. *Dead* locks are those the bolts of which require to be shot out and in by the aid of a key, etc. *Spring* locks are those in which the bolt locks itself out by coming in contact with the striking-plate. In most door locks there is a *latch-bolt,* which acts in the latter manner. The term rim applies to the *case* of the lock and its appearance when fixed; *dead* to the *action* of the *bolt; mortise* to the manner of fixing it in the woodwork flush denotes that the lock is *let into the woodwork and made flush with the surface.* Figure 173 shows the construction of a rim lock; and figures **270** and **277**, the construction of a three-bolt mortise lock.

A grave defect in most spring locks is that the bolt can be shot back (the lock unlocked) by means of a piece of sheet steel, and sufficient force applied to overcome the power of the spring.

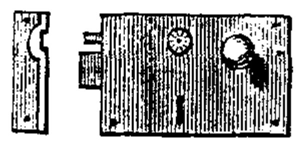
The following summary prices have been taken from the patentees' lists themselves, or have been adapted from the lists of the various makers by reducing the gross to the net cost, and then adding thereto a scale of profit which we consider fair between the purchaser and the retailer, supposing the latter "buys well." But those who are obliged either to take or to give the very long credit customary in some districts, the prices throughout would be higher in proportion.



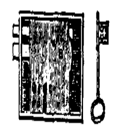
CLASS II. BRIGHT AND JAPANNED IRON CABINET AND OTHER COMMON LOCKS.



This class comprises a very immense variety, and contains locks suitable for almost every conceivable purpose. For several centuries past these locks have been made by the cottagers inhabiting the outskirts of Willenhall, as well as at Lane Head, Short Heath, and New Invention, within the township.



Nearly all the country makers still continue to make these with the same primitive tools that have been in use in the trade from time immemorial, but in the township several manufacturers have adopted the press and steam-power to their production, and the locks of these latter makers are, in consequence, far better



looking than those which are completely made by hand labour. They are made in very great quantities, principally for the foreign market.

An idea may be formed of the character of some of these locks from the fact that *"tumbler cupboard locks"* can be bought *wholesale* at 12s. 6d. per gross. "Chest locks" at the same price, and drawer locks as low as 6s. 6d. per gross, all net. An anecdote is told of a locksmith engaged in making *chest* locks having been visited by a friend in his shop, when the former dropped a lock from his bench, and went on making others without picking the dropped one up; and this being pointed out to him by his visitor, he replied— "Ah! bless thee, I can always make another before that has done ringing" —meaning that he could make another lock in less time than it would take him to pick the dropped one up, or, as he said, "before it had done ringing;" and this is the fact, for whatever number may be dropped in the course of making, they are always left to be picked up when the shop is swept. An apprentice boy will make one gross per day.

Figure **416.** These are the same as rim locks, but with the angles rounded off:

Figure **417.** A lock is made of this description which is known in the trade as n "four-inch common closet lock," and is sold at 7d. each, or with fine wards at lid. each.

Figure **423.** Best quality lock contains three wheels and hook-ward, strongly made, with double links, well finished, with stepped key. Medium quality lock contains two copper wheels and bridge-ward, fancy key-bit and screwed cap. Common quality lock contains two copper wheels screwed cap, and double hoks.

The same japanned black. Best quality lock contains two copper wheels,, thick drill-pin, S-bitted flat-bow key, double-link, tumbler, and bright brass cap. Medium quality the same, but with a bright iron cap. Common quality lock contains one copper wheel, double-link, tumbler, and japanned cap.

Figure **425.** Best quality lock contains three copper wheels, L-ward, tumbler, broad bolt, screwed cap, and flat-bow key. Medium quality lock contains one copper wheel, broad bolt strongly made, and S-bitted flat-bow key. Common quality contains one wheel and short-bitted key. These locks are frequently sold in sets of five for chests of drawers, with one, two, three, or more keys to the set as required. Per sot of five locks, with two keys, 1s. 1d. per set. If with five loose nozzles for the fronts of the drawers, 4d. per set extra. They are also sold in dozens, with three or four keys to the dozen, and are known in the trade

as "three-keyed till locks." The same kind of lock is also made for the German market with two keyholes, which are suitable either for drawers or cupboards.

Figure **110.** Best quality has two wheels, with T nose, and bridge-wards. Medium quality contains one wheel and nose-ward. Common quality contains one wheel and taper key.

Figure **431.** Common quality is complete with brass furniture and patent spindle plain spring. Medium quality is the same, but with a Scotch spring. Best quality is the same, with bolts.

Figures **432** and **433** are complete with best furniture and patent spindles.

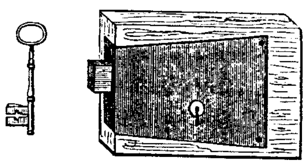

Figure **435.** Common quality is complete with the requisite ironwork. Medium quality contains full wards and an oval-bitted key. Either quality can be had with nuts and screws at 8d. extra.

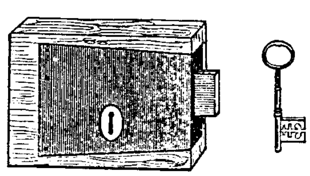
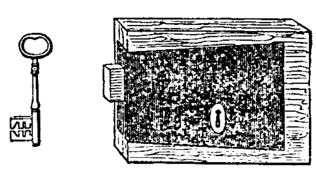
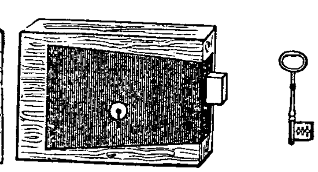


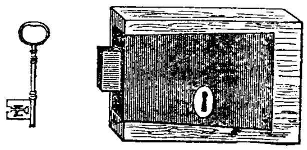
CLASS III—STOCK OR WOODEN-CASE LOCKS.



All wooden locks are called "stock locks," from the circumstance of the works of the lock being embedded in a *cavity cut out* of a block of wood to receive them. Besides the following there is another lock of this description called the "Banbury lock," in which the various limbs composing it are fixed *separately* in the piece of wood; whereas in the others the lock is first *made complete on its plate,* which is then inserted in the cavity of the stock prepared for its reception.



The *Banbury* locks are inferior, and are consequently lower in price than the following kinds:— "Steele's patent" (figures 444 and 451) is simply a *double-handed* stock lock. (See Figure **419.**)



Young's patent lock (figures **450** and **454**) has the chamber for the works of the lock to occupy formed of a circular shape, which is cut out by a tool in a the, which gives the lock a neater appearance.

Figure 454

Besides the foregoing "Fancy Plate Locks," there are other qualities known as "Bastard Plate," "Fine Plate," "Best Fine Plate or B 1," "Best Best or B B," "Common Irish," "Best Irish," and "Barrack Irish," all of which are inferior end consequently lower-priced than those described in List No. 10. The three latter sorts are made especially for and are mostly sold in Ireland. Extra best locks are made to order. Larger sizes are also made, which are principally used for church doors. There are various patterns of fancy bars (see figures 452, 453, and 454), which are charged according to the design and workmanship.

Any of the foregoing locks cap have the bar, as shown in figure 453, at 3s per dozen locks extra. The various qualities are subject to the following extra charges, viz., if made with copper wards, 6s. per dozen; if with solid brass wards, 3s. 9d. each if twice dead (ie., the bolt by a second revolution of the key is shot further out), screwed and barred, up to 12 inch, 10s per dozen; above 12 inch, 12s. per cozen; S-bits and ring-keyed, 6s, per dozen, screwing, 2s. per dozen; filling bows with brass, Is.

6d. per dozen; filling bows with iron, 3s. per dozen; if pin-bushed, 8s. per dozen; full-bushed, 10s. per dozen. Extra keys, from ls. to 2s. each.

In figures **437** to **454** inclusive, *which* represents the parts which are of brass; the *dark* shades, bright iron, or iron japanned black, and the grained portion oak.

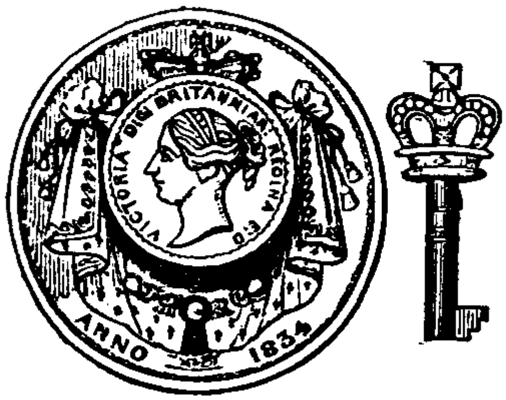

Figure 455

CHAPTER TWENTY: An Historical account of Wolverhampton; its Lock-trade and Locksmiths

It is somewhat remarkable that no historical account of the manufacture of locks, as carried on in England in general, or at Wolverhampton in particular, has ever been published. This is the more surprising, as the manufacture of locks was for several centuries the staple trade of the parish of Wolverhampton, including Bilston and Willenhall. In the few records that relate to Wolverhampton, the *lock trade is* the only manufacture particularly mentioned.

Wolverhampton, which is of great antiquity, was, previous to the introduction of lock-making altogether an agricultural town, and was celebrated for its wool. Its earliest importance resulted from the foundation of the Collegiate Church.

The followings account is taken from a loan of the town, surveyed by Isaac Taylor, and published by Thomas Jefferys, London, in 1751.

"Wolverhampton is a populous town, situated in the southeast part of the county of Stafford, in north latitude 52 deg. 40 min. (as is nearly the whole parish, except what belongs to the Church in the manor of Stowheath, whereof the Right Honble. John Earl Gower, Lord Privy Seal, and Thomas Giffard, of Chillington, Esq., a minor, are joynt lords), and is distant from London 100 computed and 130 measured miles; its present number of houses are 1,440 and inhabitants 7,454."

"This town was first called Hanton by the Saxons from its high situation, then Hamton and Wullfrunes Hamton, and so Wolverhampton, from the Princess Wulflune, its owner, a daughter or sister to King Ethelred, who came to the crown in 979; here she founded a Collegiate Church for a dean and seven prebendaries, an official, and other inferior officers, and to each of these eight she gave a power over his own lands equal to that of any lord of a manor, and to the dean the same power in spiritual matters as any bishop enjoyed, making the whole body and parish subject to him, and him subject to no man's visitation except that of the King, or Lord Keeper of the Great Seal under him. Edward the Confessor made it one of his royal free chapels, and Edward IV., in 1477, annexed the deanery to that of Windsor."

"The present magnificent church, except the chancel, was built by that great mall, Hubert Walter, A.B. of Canterbury, perhaps born here, about the year 1200. He also built proper houses round about it for the dean and prebendaries, etc., all which are long since gone to ruin; but the dean's was rebuilt by Mr. R. Guest, who farmed the excise of Oliver Cromwell, and the chancel by a voluntary subscription collected by the Reverend Mr. Allestree since that time. In 1258 Henry II. granted to the dean a market on Wednesdays, and a fair on the 26th of June; the church being dedicated to St. Peter; but tradition says they were granted by King John, his father."

"The free school was founded by Mr. Stephen Jennings, born here, who was lord mayor of London in 1509; the government and choice of the masters he gave to the Wolshipful Company of Merchant Taylors, of which he was a member. In 1714 they built the present handsome fabrick for a school and houses for the two masters. At present it has one church and three meeting houses for Roman Catholics, Quakers, and Presbyterians, all which will

not contain one-fifth part of the inhabitants, a charity school for fifty boys and forty girls. The iron manufacture and toy trade in gold, silver, brass, mother of pearl, etc., are here carried on, as also at Willenhall and Bilston, in this parish, after the same manlier as at Birmingham, Walsall, etc."

The Rev. Dr. Oliver, in his "Historical and Descriptive Account of the Collegiate Church of Wolverhampton," says— "I am inclined to think that in the time of Wulfere, the town of Hantune, now Wolverhampton, had attained to a good comparative population; which from the building of the church increased gradually to the Conquest; being improved by the weekly market held there which was probably established before that period. But it does not appear to have been a town of general trade in those early times, for in the reign of Edward III. the Nona Roll states that the town had no merchants."

"The alteration which the face of the country about Wolverhampton has sustained from the time when Wulfruna flourished is striking beyond conception. Formerly it was a retired district, abounding in groves and streamlets, and occupied by a pastoral population, who were employed in tending cattle and feeding swine, which latter were herded in innumerable quantities amongst the woods and forests, and collected at night in a place called Swinesta (i.e., porcorum stabulum forte', vel haram), between Wolverhampton and Bilston; while the iron and coal lay quietly beneath the surface, undisturbed by the restless cupidity of man."

The forests were well stocked with deer, and the country intersected with paved roads, and crossed by at least one military way. Numerous small streams irrigated the herbage, and afforded nourishment to the cattle with which the district was stored. At present the herbage and all other natural productions have vanished before the speculations of commercial enterprise, and it has become a region of darkness and steam-engines.

The fitful appearance of numerous detached fires, the hissing and booming of the furnace blasts, the loud and frequent reports like claps of thunder from the iron forges; the dense clouds of smoke which always envelope this sterile tract, intersected by sluggish canals; the abundant population that swarm throughout the district men and women alike habited in the dark livery of the mine-combined with the appearance of total desolation which is everywhere exhibited, overwhelm a stranger with sentiments and feelings which he is at a loss to define; but they are usually a

mixture of pity for the presumed misery and privations of the people, and congratulations on the comparative felicity of his own lot, which has not been cast in such a dreary and inhospitable climate. In reality, however, the situation is perfectly wholesome and healthy, and the people generally, working at good wages, are happy and contented."

The particular year when the manufacture of locks commenced in Wolverhampton or the circumstances which led thereto, will perhaps never be known, but the fact of the iron (which was previous to 1768 all smelted with wood) being of a very superior quality, might have drawn the artisans here, or might have initiated the trade itself.

By the extract from Dr. Plot's "Natural History of Staffordshire," published in 1686, it is manifest that the manufacture of locks was the principal trade of the town, if not the only one, at that period.

Another notice of Wolverhampton occurs in the Harleian Manuscripts, which give an account of "The Voyage of Don Manuel Gonzales (late merchant of the city of Lisbon, in Portugal), to Great Britain; containing an Historical, Geographical, Typographical, Political, and Ecclesiastical Account of England and Scotland, with a curious collection of things particularly rare, both in nature and antiquity." This MS. was written about the year 1732, and was translated from the Portuguese, and printed in Pinkerton's Collection of Voyages and Travels. He says, "Wolverhampton in Staffordshire, about 117 miles from London, was anciently called Hampton, and so large a parish that it was nearly thirty miles in compass, and contained seventeen great villages."

"A priory was formerly built here by King Edgar, as Sir William Dugdale says, at the request of his dying sister Wulfruna; and for this reason the place was called Wulfrune's Hampton, which is since corrupted to Wolverhampton. It stands upon high ground, and is a populous town, well built, and the streets well paved; but all the water the town is supplied with, except what falls from the skies, comes from four weak springs of different qualities, which go by the names of Pudding-well, Horse-well, Washing-well, anti Meat-well; all appropriated to their several uses. From the last they fetch all the water which they use for boiling or brewing in leather-budgets laid across a horse, with a funnel at the top, by which they fill them; and to the other three wells they carry their tripe, horses, and linen.

To this scarcity of water and the high situation of the place is ascribed its healthy state, in spite of the adjacent coal mines; and it is said the plague was hardly ever known here, but the smallpox often, which has been observed to be an indication of the wholesomeness of the air. The chief manufacturers of this town are *locksmiths,* who are reckoned the most expert of that trade in England."

The town (which contained 7,454 inhabitants) had now (1750) become of great commercial importance. It retained its agricultural celebrity, and was the chief town of a district exceedingly rich in those three most valuable minerals: coal, ironstone, and limestone.

Besides the lock manufacture, the fancy steel-toy trade, comprising fine steel watch chains, buckles buttons, ornamental sword hilts, etc., all of which were produced in a costly and superb style, was at its height, and the foundation of all the trades of the ironmongery or hardware line, and of which brass, iron and steel form the component materials, and which latter trades have since assumed such vast proportions, were firmly established.

The following interesting table, which we have compiled from various sources, shows the rapid increase of the houses and inhabitants (Wolverhampton only), at various periods from the year 1750 to 1851:

Year.	**Houses.**	**Inhabitants.**
1750 ...	**1440 ...**	**7454**
1801 ...	**2532 ...**	**12,566**
1811 ...	**2937 ...**	**14,836**
1821 ...	**3612 ...**	**18,380**
1831 ...	**---- ...**	**24,732**
1841 ...	**7481 ...**	**36,382**
1851 ...	**9807 ...**	**49,989**
1855 ...	**---- ...**	**57,000**

The following is the number of houses and inhabitants in each street, in 1750:—

	Houses	**Inhabitants**
Belcroft Street	**24**	**160**
Berry Street, Workhouse, etc.	**91**	**599**
Boblake and Barns Street	**180**	**888**

Cock Street	**43**	**175**
Courts, Alleys, and Back Buildings	**52**	**237**
Bilston Street and Manor Lane	**114**	**784**

From the commencement of the present century Wolverhampton has increased in population, wealth, and importance more rapidly perhaps than almost any other town in the kingdom. Its race of wealthy ironmasters, and factors or merchants, have since the middle of the last century established an extensive trade with almost every part of the habitable world,, and whose industry, energy, and integrity of character are proverbial with the commercial classes in every part of the kingdom, and we may say, almost throughout Europe.

Other trades were now beginning to take root in Wolverhampton. The tin-plate and japan busisnesses which at the present time employ a larger number of hands than any other branch of trade in the town, were about this period firmly established, having been originally introduced about the middle of the last century.

We can only *name* the principal buildings and institutions of this town, as other particulars relating thereto would only be interesting to the inhabitants of the district.

	Houses	**Inhabitants**
High Green and Dudley Street	**214**	**1032**
Horse Fair	**55**	**264**
John Street	**66**	**335**
Lichfield Street	**57**	**228**
London Row	**22**	**148**
New Street	**14**	**77**
Rottons Row	**112**	**527**
Stafford Street and Middle Row	**127**	**718**
Tup Street	**209**	**854**
Worcester Street and Brickhill Lane	**60**	**428**
Total	**1,440**	**7,454**

In addition to the public edifices which existed in 1750 and noticed before, there have been erected since that period numerous temples for the worship of the Most High, as well as schools for the education of the children of the working classes, including a Ragged School and an Orphanage, which latter we take especial pride in naming as the noble and elegant building owes its foundation to the literality of a worthy man, whose father, by trade a keymaker, from the superior excellence of his work,

was called by the trade the "king of the keysmiths." Many a widow and many an orphan will rejoice in the circumstance that the son of such a "king" appreciating the value of a good education which had been purchased by the industry of his revered parent, by the utter forgetfulness of self, should have conferred the blessing of a sound and religious education, together with board, clothing, and lodging, on the many orphans who have already been admitted into the institution.

Figure 456. View of Wolverhampton in 1805. (From Bisset's Grand National Directory of that year.)

The South Staffordshire Hospital, situate in the Cleveland Road, is a fine structure, built in the Italian and Roman Dorie style of architecture. It was built by public subscription, and is supported by voluntary contributions.

The town, which was incorporated in 1848, contains a Town Hall, Public Office, Market Hall, an extensive and well-planned Cattle Market, a Fat Pig Market, a Corn Exchange, a School of Design and Practical Art, a Library, a Mechanics' Institution, a Theatre, Baths, Gas Works, Water Works, and the largest provincial Suburban Cemetery in the kingdom.

The London and North Western, Shrewsbury Birmingham, and Stour Valley Joint Railway station, and that of the Great Western, and the Oxford, Worchester, and Wolverhampton Railway Companies are situate nearly in the centre of the town, and comprise extensive erections. The town has also water communication by means of the Birmingham and Liverpool, the Stafforclshire and Worcestcshire,

and the Wyrley and Essington Canals, with every part of the kingdom.

The town was made a Parliamentary Borough at the passing of the Reform Bill in 1832, which includes Bilston, Willenhall, Wednesfield, and Sedgley, and returns two members.

We could say much more about this growing borough, but our space forbids. As before stated, it was in the sixteenth century that the lock-trade was at its height, not only in England, but also in France and Germany; and though we have no published records which describe the peculiarities of the construction of the English locks of that period, or other particulars relating thereto, yet there are numerous specimens which have been handed down to us which prove the ingenuity and taste of the locksmiths of that time. The ornamental and artistic designs of these locks and keys have never to the present day been excelled. We have, in chapters 13 and 18, given numerous drawings of locks and of the above early date, which will serve to indicate the steps by which such perfection in the art was arrived at.

Although Wolverhampton has always been the great storehouse whence locks were obtained, and is known commercially as the chief *locale* of the English lock-trade, yet it is at Willenhall, a township in the same parish, about three miles distant on the Lichfield turnpike road, that the great bulk of the common locks are manufactured in all their details. The better quality of locks are almost exclusively manufactured at Wolverhampton.

In 1770 there were the following locksmiths in the parish:

Wolverhampton	**134**
Bilston	**8**
Willenhall	**148**

At this period no patent had been taken out for improvements in the construction of locks and latches; nor for anything in any way connected with the trade, although the patent law had been in existence from the reign of James I.

In the year 1855 the number of master locksmiths in business in the district was as follows:

Wolverhampton	**110**
Bilston	**2**
Willenhall	**340**

Willenhall, as before stated, is not only the principal neighborhood for the production of locks and latches, but also for the manufacture of bolts, gridirons, currycombs, etc. Almost the entire population are employed in the various branches of the above manufactures, as up to the year 1844 there were but two inhabitants who were not engaged in business, and these were the clergyman of the township and the Wesleyan minister. At this period (1844) there were neither a resident magistrate, lawyer, or policeman.

This busy hive of the "Sons of Vulcan" has since 1801 increased in population five-fold, numbering now (1856) at least 15,000 souls. These are not all employed in the above trades, as since the mines of coal and ironstone in the immediate neighbourhood have been proved to be so rich and extensive, many of the persons employed in connection with these mining operations reside in the town.

There are, however, at the present time about 340 of what are termed "master men," the greater part of whom are in a small way, employing only a few hands each, and these are mostly apprentices. These small masters having no capital, and being very poor, are compelled to sell the produce of one week's work before commencing the next. They must sell their wares at some price, the principal purchasers being the Wolverhampton factors. This circumstance tends to keep down the price of the various kinds of manufactured goods, and hence the apparent, nay actual poverty of this humble class of manufacturers.

Amongst such a large number of master men, it would be strange indeed if there were none in a better condition; and on a recent visit to the town we were informed that there were a goodly number who had small manufactories, and were in thriving and well-to-do circumstances. Within the last few years numbers of this latter class have erected premises of some pretensions on their own freeholds, several of which are of considerable extent and importance, and far excel all other similar manufactories at Wolverhampton.

One of the largest concerns is that of Messrs. John Harper and Matthew Tildesley, and is called the "Albion Works," where the various kinds of locks described and illustrated in the last chapter, together with bolts, wood screws, etc., are produced in vast quantities. We here inspected many different samples of locks, etc., including patterns of locks, handles, bolts, and

bars used in the plantations of South America, which are made in large quantities, and are supplied at regular periods.

Figures 457 to 462 inclusive represent a set of these latter fastenings, which are larger than any we have ever seen. These figures also form a good illustration of the Willenhall manufactures. Messrs. Harper: and Tildesley are also the sole manufacturers of a patent tumbler padlock (see figure **426**), which is very saleable in the Levant and East India markets, and for simplicity and cheapness is one of the wonders of the age.

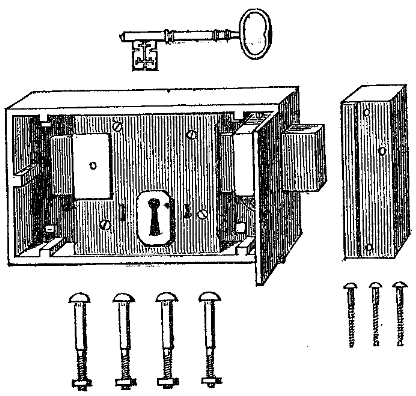

Figure 457

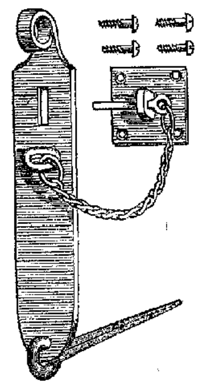

Figure 458

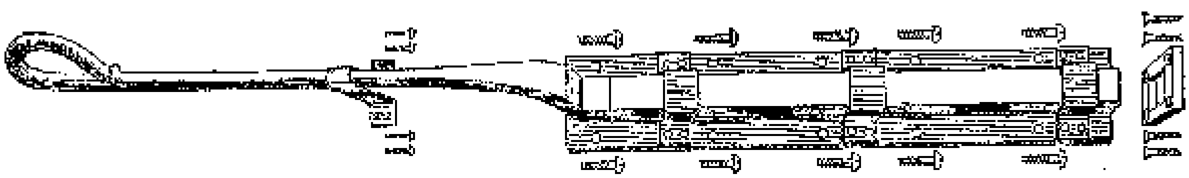

Figure 459

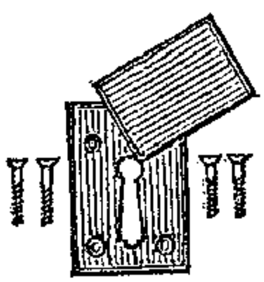

Figure 460

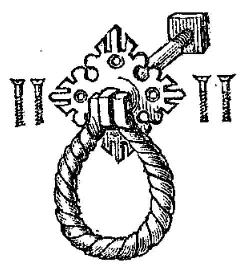

Figure 461

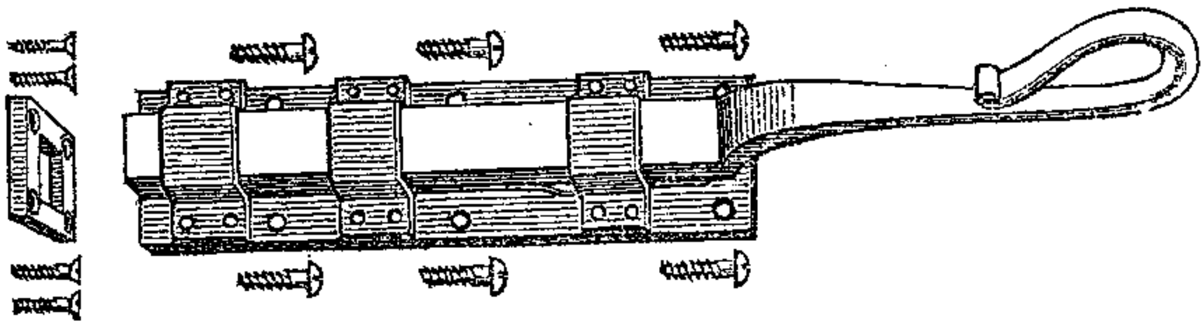

Figure 462

It is without exception the cheapest padlock in the world, as it can be sold retail from one penny each. They have been sold wholesale in quantities varying from five to ten thousand dozens at a time.

Although the principle of division of labour is not carried out to the extent it is capable of in the manufacture of locks and keys, yet many operations are carried on as distinct trades, as for instance key-stamping, pressing, casting, etc.; and it is interesting to note when some of these branches of the trade were first introduced, the circumstances which led thereto, and the results consequent upon their adoption.

We have before assigned as a reason for the establishment of the lock manufacture in this district to be the excellent quality of the iron before it was smelted with pit coal; and it is worthy of notice that many of the Willenhall little manufacturers still use no other than the very best *charcoal* iron, not, as may be supposed, for *best* work, but for many kinds of common locks, &c. A very superior quality of iron used to be made from the "swarf" or filings of iron, and hence called "swarf iron."

This iron was used formerly for all particular purposes in forged work, and even for links for best chest locks. A Mr. Daniel Daker, of Darlaston, used to go round the district collecting the swarf from the locksmiths, which he made into "swarf balls." Mr. Richard Tildesley, a cabinet or bright lock-maker, who died so late as the year 1816, not only used this iron for his "links," but he also bought old horseshoes, from which he made the internal parts of the locks.

The great grandfathers of some of the oldest inhabitants of Willenhall, in their day, had to work down thin iron for "lock-plates," &c., from *bars* which were considerably too large

for their use. Rolls for rolling sheets and plates were then unknown. It was the custom with the masters, towards nine or ten O'clock at night, to say to the apprentices, "Now, lads, leave work and come and strike," which was the process employed for drawing the bars of iron to a proper strength and size for use, as at that period iron was not made as it is now of every size and shape suitable for the various articles it may be required for, and hence called merchant iron. In connection with this subject an anecdote is told of a hard-working man, who had two apprentices and a spendthrift son named Tom. At night he had these two boys to strike the iron in the manner before described, when he (the master) would drop his hammer on the anvil between each blow, which his neighbours said chimed "Dad gets it—Tom spends it." "Dad gets it—Tom spends it."

In bolt-making, about 40 years ago, the plates were cut from sheet iron with a small pair of shears, and the screw and rivet-holes were punched out over the vice. Round bolts were then worked down from square rods; a process also done by a forger and strikers. Padlock shackles were also forged from square rods, and the plates cut into the required form with a pair of shears and a chisel upon the anvil.

Such was the crude method of forming parts of locks previous to the year 1790, when a Mr. Isaac Mason, of Bilston, introduced the present method of *pressing* various parts of locks by means of tools and the ordinary fly press. In the year 1796, Mr. Mason was induced by John Beebee, Esq., a factor, to take up his residence at Willenhall, where he carried on a lucrative business for many years. By the adoption of the press an immense amount of labour has since been saved. To this same Mr. Mason belongs the credit of adopting *cast* iron, both common and malleable, for lock purposes, about the year 1810, but who, after spending considerable sums in trying to produce the iron of a proper quality, finally abandoned the project in 1817.

The lock-makers were then dependent upon Birmingham ironfounders for their malleable iron castings, which were at that period used in very large quantities for Dutch and Spanish locks by Mr. William Badger, and afterwards by John Collett, whose family are still largely engaged in manufacturing common Dutch locks. The great demand for this class of work led Mr. Wells, of Walsall, to commence casting, and the various limbs were retailed by Mr. Joseph Hodson at so much per dozen—not by weight, as at the present time.

In 1830, Mr. Richard Tildesley (son of the Mr. Richard Tildesley before named), then a brassfounder, was the next to make another attempt at casting common and malleable iron for lock purposes, but which, like the preceding one of Mr. Mason, proved unsuccessful.

It was not till the year 1836 that the next attempt to perfect the manufacture of malleable iron castings was made in Willenhall, when the still increasing quantity weekly consumed in the fabrication of the different kinds of locks induced Mr. Richard Tildesley to make further experiments to accomplish this great desideratum; but who, like his predecessor, after spending a considerable amount of money, relinquished further trials. However the circumstance of being still compelled to obtain these castings either from Walsall or Birmingham induced Mr. Tildesley subsequently to try again, when at length his perseverance and labours were crowned with success. There are now (1856) three ironfounders in the township, Mr. Richard Tildesley, Mr. Knowles, and Messrs. John Harper, jun. and Co. We believe this latter firm were the first to produce locks entirely of *cast malleable iron,* and the perfection to which they have brought this branch of the lock manufacture may be estimated from the following figure, which represents a Bramah key as it came from the sand. It is without a mark or blemish of any kind, and the cuts in the barrel are quite perfect. The fineness and clearness of surface and its malleability far surpass anything of the kind we had ever before examined.

Fig

Prior to the year 1806, most, if not all of the keys used in Willenhall had to be forged, as before stated, from "swarf balls," when about this period several parties in Birmingham commenced *to stamp* keys and supply them (called key-blanks) to the Willenhall locksmiths.

In 1810, Mr. Hope, of Compton, near Wolverhampton, also commenced key-stamping, in which he soon excelled all other stampers, and has continued to the present day to turn out very superior work.

In the course of our researches we were shown a list of prices issued in 1810, jointly by the keymakers of Birmingham, John Grimley, William Taylor, and Charles Ash, in which the price of small keys was at that time 4s. 6d. per gross. Now the same sized keys are sold at 1s. 8d. per gross, and if made of malleable iron at 10d. per gross.

For some time, prejudice, that arch enemy of everything that is

new and of every attempt at getting out of the *beaten track,* prevented the general employment of *stamped* keys, but ultimately (1811) one of the above-named persons was induced to leave Bilmingham and commence key-stamping at Willenhall. In 1812, John Grimley also commenced there in the same business, and whose sons and grandsons continue to carry on the trade; so that the laborious and slow operation of *key-forging* soon became extinct, at least nearly so, there being now (1856) but "one" left, and his services are only occasionally required.

"Lock-making, as carried on in Willenhall, is divided into mortise locks, box and trunk locks, cabinet locks, rim locks, bright locks, brass-case locks, closet locks, dead locks, and padlocks, in iron and brass. Except some of the parts of the brass-work, which are cast, the processes by which all these locks are made are forging, pressing, and filing. The forging is a light process of smith's work, affording variety of action in the use of a light hammer, and blowing the bellows. Children and young persons are employed at it. *Pressing* is work done at a press, by which certain parts of the lock are pressed, i.*e.*, stamped or cut out."

"The presses are of various sizes. All require strength; the large ones considerable strength. This press has a horizontal lever, the centre of which (if it have two arms) crosses the top of a perpendicular screw, which is the fulcrum. There is generally an iron weight at each end of the lever, according to the power required. One of these arms of the lever is grasped by the right hand of the presser and whirled round with a jerk, while the fingers of the left hand place the metal to be worked upon, and remove it at each operation. Very often the press has only one arm, i.*e.*, a lever, one end of which is fixed in the top of the screw; perhaps, also, it has no weight at the other end. Children and young persons are employed at it."

"The age and strength of the child, and the power required, as well as the hours of labour, should be properly adjusted, which they very seldom are. Filing is the most general of all the processes, and is prolonged indefinitely, and with scarcely the least variety of action. Children are placed standing upon blocks so as to be able to reach the vice, and set to work with a file almost as soon as they can hold one. Key-making is divided into light forge-work, stamping, piercing, and filing. The forging, as previously described, is light smith's work."

"The process of stamping is effected by placing the end of

an iron wire, taken red-hot from the forge, into one-half of a key-mould, made in a kind of anvil or block. A heavy weight is then raised between an upright frame-work, in the grooves of which it runs (like the knife in a guillotine), by means of a cord, which is drawn by both hands, with the assistance of one foot in a stirrup attached to the end of the cord. At the bottom of this weight, thus raised, there is the other half of the key-mould. The foot in the stirrup being suddenly raised, and the cord loosed, the weight falls upon the red-hot wire, and the blow stamps it into the two moulds, which are brought accurately together by means of the slides or side-grooves in the framework in which the weight runs."

"The rough key is also trimmed and cleared by this stamping apparatus; that is, the surplus metal all round is cut off by a single blow from above, and the metal which fills up the rim or ring is punched, cut, or stamped out by a blow given in the same way. Children never use the cord and stirrup, as they have not strength to raise the weight. It is always done by adults, or by young persons of at least sixteen or seventeen years of age. Children and young persons very commonly do the forgework; the former blowing the bellows, and the latter placing the heated rod in the mould below, either for stamping the key, or trimming, and clearing it.

The *piercing is* making the hole or pipe of the key, which is drilled by a small machine worked with the foot, like a lathe. This is done both by young persons and children, but seldom under eleven years of age, as it requires skill. *Filing is* the process that finishes the key. The wards are cut, and the key made bright entirely with the file. Children and young persons work at this in all descriptions of common keys. Keys that have complicated wards are only entrusted to adults and to apprentices of some years' practice"

We have previously described various improvements which have been introduced from the earliest times to the present day into the manufacture of locks and keys, but it will doubtless surprise many of our readers to find that these improvements are so few in number; but though few, still they have been of vast importance to the trade, and the only wonder is that other improvements, the want of which has all along been so apparent, have never yet been introduced, as for instance the adoption of machinery to do half the work that is now done by hand.

In prosecuting our inquiries in connection with this subject, we

were astonished to find that, at Wolverhampton, the Messrs. Chubb and other large makers should still produce the whole of their work with the same primitive tools which have been in use from time immemorial; they do not employ a single machine, and we believe throughout the trade in this district the only makers who use machines at all are Mr. Duce and Mr. Aubin. That most of the limbs of which a lock is composed are capable of being produced at a much cheaper rate, and with a degree of uniformity impracticable by hand labour, has been lately proved by Messrs. Hobbs, Ashley, and Co., of London, whose machines, invented by Mr. Hobbs, are not only of the most interesting character, but perform their work in the most admirable manner. Mr. Hobbs, who has twice thrown open his establishment for our inspection, and who has in the most unreserved manner given us all the information we required on various matters connected with this subject, and also with respect to each machine, has commenced a course of action, which must ultimately lead to success.

The only doubt we have, is, whether London is the right place for establishing a lock manufactory, as the materials and some of the separate parts of the locks must be had from this district. The operatives, also, must be drawn from this town.

It is almost incredible that even in making "stock" locks at the present time, not a circular saw nor machinery of any kind is used. The cavity for the works of a double-handed lock (Steele's patent) is bored out with a hand auger and finished with a chisel, the block of wood being tightly screwed in a vice. The wood used for these locks is oak (pipe staves), and when Quebec timber is employed, from its hardness and roughness, the labour in working it by hand is very great, yet not a single maker has had the temerity to introduce the circular saw, which in other manufactures has produced such beneficial results. In making the *iron parts,* not even a press is used; all the holes being punched out by hand. The *plates* are cut out by hand also, and the *bolts* are all forged. The principal tools are the shears, file, and punch. The great waste of materials consequent upon such an antiquated system of manufacture is very considerable.

The patentee of a lock, who was not a lock-maker, and consequently had no feeling of attachment for the "things of old," came to Wolverhampton for the purpose of having his locks made, and called upon one of the principal manufacturers for that purpose. Part of the arrangement entered into comprised the purchase of a new and powerful press, which the manufacturer duly procured, and the patentee was shortly afterwards requested to

come and inspect it. He did so, and found to his amazement that it had been constructed out of three or more *separate* parts, bought at as many second-hand establishments. This is an apt illustration of the kind of enterprise the master locksmiths of Wolverhampton possess; and we feel assured that whatever *great* improvements are to be introduced into the trade generally, they will emanate from persons altogether unconnected with the manufacture. Such has been the case with nearly every other manufacture, the particular improvements in which have mostly been the work of inventors not belonging to the particular trade.

If our Manchester friends should become slack of orders we would recommend them to come and inspect the "antique" tools of the Wolverhampton locksmiths, and at once design the machinery which must some day cause a revolution in the lock trade.

The manufactories here are as antiquated as the tools, and are quite as susceptible of improvement. There is only one that has any pretensions to importance, and that is Messrs. Chubb's, in Horseley Fields, which was formerly the old Workhouse.

This, together with all the minor establishments (with one or two exceptions), are ill-contrived low buildings, badly lighted and worse ventilated. The workshops of the humbler masters are regular menageries, dogs being tied up under the bellows; bird-cages hung in the windows; rabbit-pens constructed under the work-bench; pigeons kept outside on the roof. The windows, which act as ventilators in summer, in winter form specimens of *marqueterie* work, made with paper, sheet iron, tinplate, &c. A pigsty under the workshop window and its accompanying tender—the wash tub—near it, with the accumulated dust and dirt of the floor, form the enchantments of a locksmith's shop.

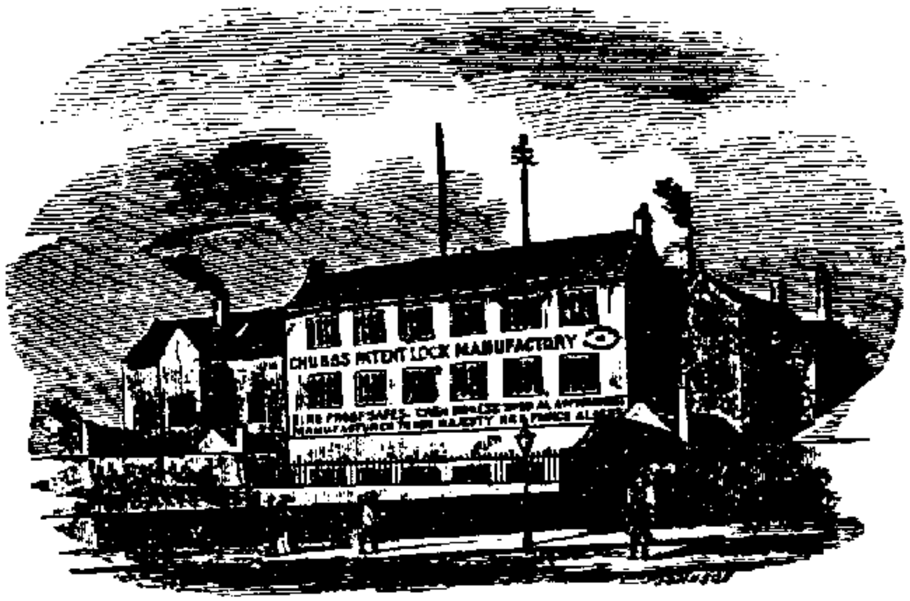

Figure 464. Chubb's Lock Manufactory, Horseley Fields, Wolverhampton. (Drawn November, 1856.)

Amongst the old buildings of the town the premises now occupied by Mr. Fleeming, chemist, High Green, possess considerable interest in connection with the lock manufacturers of this district, as the house was formerly a very celebrated inn, known as the "Angel," and it was this house that the locksmiths were in the habit of frequenting for the purpose of meeting the foreign merchants and country buyers. The Swan Hotel adjoining was originally an inn, at which the same class of masters and purchasers also assembled.

The custom appears to have been for the manufacturers to take up their standings outside and next to the doors of these two houses in the order in which they arrived. The American merchants were the principal customers, and it was usual for the latter in making a bargain to sell to the manufacturer a barrel of flour. Each seller had also to take a ticket from the innkeeper for a pint of ale, as a consideration for the accommodation afforded. It is stated that scarcely an instance occurred without the whole of the manufactured goods having been thus periodically disposed of. This custom prevailed till the enactment of the Corn Laws.

We have endeavoured to find out the period when the "factoring trade" was first established in this district, but our efforts have been unsuccessful That the sales of manufactured goods were formerly effected *direct* between the foreign merchants and country dealers and the producers is beyond question; and that

some of the foreign merchants had resident agents here, who bought the goods and shipped them off by canal, is also certain.

Some think that the factoring trade originated from the circumstance of the foreign merchants and the country buyers having "bantered" the manufacturers in the price of their goods, when the producers reduced the quality in proportion, and, as some say, sold them locks without keys, which, when discovered, caused a feeling of distrust on the part of the buyers, and made them afraid to purchase direct. They then employed a middleman to make their purchases, who was afterwards called a "Chapman," and subsequently "factor." In using the term "factor" in any other part of the kingdom to designate a trade, it would at once be asked what: cheese, butter, or bacon?

But in this district the term is synonymous with merchant, and is understood to mean only a wholesale dealer in hardware and other goods. Originally the chapmen, although wealthy, did not travel or send out representatives, and it is said they lacked the enterprise in this respect of their brethren of Birmingham, and allowed the chapmen of that town to get the start of them. Some, however, by degrees added the country to their foreign trade, whilst others continued alone, the latter business.

The representatives were then called, not as now by the dignified title of "commercial travelers" but "outriders," a very significant term, for they used to travel on horseback with their samples in their saddle-bags. The saddle-bags and horse afterwards gave place to the box and gig, and the latter is becoming in these railway times almost as great a novelty as the former.

Although the foreign merchants had from the circumstance before named ceased to come to the town, the manufacturers still expected them, and continued making stock in the anticipation of the whole being some day cleared off by these large buyers, when, after hoping against hope, they went and offered their goods to the factors, who told them that they (the factors) did not require such merchandise, but if they (the manufacturers) would reduce their respective prices five or ten percent, then they would purchase and take the goods into stock,.although they had no orders for them. This is said to have been the origin of the present system of discounts so universally adopted, not only in the lock-trade, but also in almost every other branch of the hardware manufacture.

Whether this would apply to all other trades we do not know, but that it was the case with the lock-makers we have every reason to believe, for several aged locksmiths recollect the time when discounts were unknown, and when locks which are now sold wholesale at a reduction from the original price of from 10 to 75 percent, were formerly sold net.

We have heard many droll anecdotes relative to the first establishment of these discounts. Some of the manufacturers, when it was first proposed to them, did not even understand the meaning of the word, whilst others, not only at that period, but even to the present time, from ignorance of the difference between discount and interest, have come to ruin, at the same time that they supposed themselves to be saving money; for so soon as the principle of discounts became a rule in the trade, the various manufacturers, as they invented new things or improved old ones, in calculating the price they could sell them at, would put on a certain amount of interest on the prime cost of the article, for the purpose of taking it off again to the factor; and this in most cases was reckoned thus: If the particular article had cost the manufacturer 3s. 9d., which, with his profit of 3d. added would make 4s., he would add to the latter amount 25 percent interest, for the purpose of allowing the same discount to the factor, which made the gross price 5s., and with 25 percent *discount* off, reduced it to 3s. 9d. net, which was, as stated before, the actual prime cost of the article.

We will illustrate this further by relating the following anecdote, which was told to us as a fact, and which we believe to be quite true: A small manufacturer, who had been started in business by a factor, kept so many journeymen, and on the Saturday night, after drawing his money from the factor for so many dozens of locks made and delivered, gave the amount, as is customary with this class of the commercial community, to his "better half" to pay the journeymen their wages. After paying most of them, and the good dame being requested by her lord and master to pay the remainder, she replied, and we think very prudently, "but Thomas we shall have no money left for ourselves." "How can that be?" replied the master; "I have made and drawn for so many dozen, and I reckon to get so much by each dozen after *putting on the discount;* there must be plenty left. "The good wife paid all the men, but the cash left was indeed "small and beautifully less" —it was simply the difference between putting on the discount and taking it off again."

All the *master* locksmiths, with a few exceptions, work at the vice themselves, and it is a rare circumstance to see one in the streets without his apron on. They have such an attachment to the apron that it is said some of them decline going to a place of worship, because they should have to "doff the apron."

The *journeymen* locksmiths, as a class, work hard when at their work, but are much addicted to drinking. Most of them are in a very degenerate state, and few seem inclined to better their condition. Little hope can be entertained of their improvement till the abominable system of hiring is abolished. The following extracts on this subject in Mr. Home's report before referred to, although written fifteen years ago, equally apply at the present time, and we insert them at length in the hope that they may arouse the philanthropic spirit of our townsmen to make an effort to abolish the system altogether. We hope the magistrates who adjudicate upon these cases will give the weight of their influence in assisting to do away with this system of English slavery. Its demoralizing effects cannot for one moment be doubted, and we feel convinced of the impossibility of improving the moral condition of this class of our working population till its eradication is complete and final:

"When a large master engages an adult, it is very common for the former to offer to lend the man money. This money is to be returned by weekly installments from the man's wages, and will generally require *at least* a twelve month term to be thus repaid at 1s. 6d. or 2s. per week. Hence the man indirectly hires himself for at least a twelve month period. Two years are a more common period by means of these kind of contracts, but as these weekly installments are very seldom strictly enforced, and never enforced when the man has paid up pretty regularly to a certain extent, it may well be expected that the man is far more glad to avail himself of the extra 1s. 6d. or 2s. a week than anxious to get out of debt. Thus, at the end of the year he is not again a free man, but is required to work as many more weeks as will pay up the balance by the installments. While doing this the master offers to lend him another sum of money on similar terms."

"The man cannot resist the temptation of having the means of a week's riot and debauchery, and he enters on a fresh contract of service for a year and a half, two years, or more, according to the amount of the sum and the weekly installment. It hence appears that the object of this loan of money from the master to the man is to create a debt which shall govern the period of service. A man, for instance, is engaged on the loan of £2 12s.

to work for a master until such sum shall be paid by weekly installments of 1s. Suppose a default is made in the payment of the installments, the *service* must continue until such payments are made in that particular way; which service would extend to the termination of the man's life if he continued a defaulter."

"That these contracts are sufficiently stringent on one side and loose on the other may be readily apprehended. They are drawn up by an attorney who is employed by the master. The following is from a copy of an agreement of this kind:—"

"First the said R.0— hereby agrees to hire himself to, and to work solely for the said J.H. his executors, administrators, and assign, for the term of one hundred and four weeks, at the work or trade of rim lock making, etc; and the said J.H-, his executors, administrators, and assigns shall be at liberty to retain out of the wages or earnings of the said R.O- the sum of two shillings and sixpence per week, till the sum of thirteen pounds is fully paid, which is now due and owing from the said R.O— to the said J.H-. If the said R.O— shall borrow any more money of the said J.H- while he is fulfilling his number of weeks as a contract servant, he shall in no *wise leave the service* of the said J.H-, his executors, administrators, and assigns, so long as he is indebted to them, etc."

The following clauses occur in a copy of another of these agreements:—

"And it is agreed by both parties that the acceptance by the said servant B.S—, at the usual reckoning times, *of any sum* as his wages, except expressly paid on account, shall be conclusive of a settlement; and it shall not be lawful for him again to dispute the amount, or open the account."

"That in case at any time the said master J.C- shall advance any sum of money to the said B. S beyond the wages then due, it shall be lawful for him to retain out of the wages from time to time to become due to the said B.S- by installments of [ ] shillings per week, until the whole of such advancement shall be paid: And this contract, and the term of service, shall extend and subsist until the sum be fully paid by such installment, notwithstanding anything herein to the contrary."

"These kind of contracts also contain other stringent clauses, such as compensation 'out of the wages' for work not well done or damaged. From the operation of this kind of

contract it happens in very few instances that a man is free, or has any definite period of service. The good of this system is that, if the master be a wise and benevolent man, the power he thus possesses over the servant may be beneficial to both parties. The evils of the system are these:— First, that as all masters are not wise and benevolent, it gives them a power which is liable to be abused in all the intricate ways of Tommy. Secondly, that it incites the man to a system of borrowing and of extravagant riot, in which the loans are almost always expended. Thirdly, it puts the means out of a man's power of availing himself of any opportunity that might occur for bettering his condition. The man has sold himself."

"Should a master and a man agree to part, the first question with a new master is, 'What do you owe your last master?' The new contract is founded upon the repayment of the last master by the new master (the former consenting to receive the sum of money) and an advance is again made to the man on the same terms, carrying on the whole debt. Hence the man is passed, with an accumulating debt upon his head, from one master's hands to the other. The man knows he shall never recover his freedom, and becomes reckless. Since a loan is made with every fresh engagement, he endeavours to change as often as he can."

"But very often the man breaks through the contract he has made with his master on account of money lent, and insists upon leaving the master. The master, not agreeing, insists upon the payment of the money remaining due to him by weekly installments, say £2, together with the current service. But suppose the man can raise the £2, he is still not free to leave upon paying it, for the master refuses to receive it, as not being according to the contract, which was by weekly installments from wages for work performed. The man refusing to fulfill this, the master instantly gets a warrant out against him; takes him before a magistrate and the man is forthwith sent to Stafford Jail. On his liberation he still has to fulfill his contract of service and payment of his debt by installments. In the course of the last four years there has been, on an average, other towns of the county inclusive, two hundred and forty individuals sent to Stafford Jail each year for this very offense. The expense to the county thus incurred is prodigious."

"I question the legality of the whole proceeding; for if the man offer to discharge the money debt at once, and the master refuse to accept it, then the remainder of his claim (except he can prove subatantial damages by the departure of the man at that

time) would surely be accounted, in equity, as frivolous and vexatious, and conspiring against the liberty of the subject. If a man agrees to work until he has paid his master fifty-two shillings by one shilling per week, this would be equivalent to a hiring for one year certain; and if, at the end of that year, any sum remained unpaid, I should conceive it would be a debt which, legally, had nothing to do with the service. But if the man engaged to *work* for the master *until* he paid him fifty-two shillings, that would be an indefinite contract as to time, and therefore voidable at any time. Now, in both cases, the magistrates enforce the service until the debts are discharged. They take no notice of the default of payment of any installment, (to which default it is probable the master has no objection), but only of the default of service while the debt is due."

Mr. Horne makes the following remarks relative to the physical labour of the locksmiths of Wolverhampton and Willenhall.

"With the locksmiths and key-makers the work becomes most injurious from the sameness of the position of the body and action of the arms, and the long protracted hours during which they stand filing at a vice."

"Physically injurious as these processes become here, [Wolverhampton] they are rendered far more so by the locksmiths and key-makers of Willenhall."

"The right shoulder-blade becomes displaced and projects, and the right leg crooks and bends inwards at the knee, like the letter K. It is the leg which is hindermost in standing at the vice. One of my witnesses who was accustomed to the sight could not help terming it 'hind leg,' so impressed was he with its similarity to that of a drudging animal."

"The right hand, also, has frequently a marked distortion. Almost everything it holds takes the position of the file. If the poor man carries a limp lettuce or a limper mackerel from Wolverhampton market, they are never dangled, but always held like the file. If he carry nothing, his right hand is in just the same position."

"I have heard several inhabitants of Wolverhampton declare they can recognize a Willenhall man whenever they see one in the streets. Probably this requires some qualification; at all events I believe I could do the same myself if he were a locksmith, almost at the first glance."

The hours of labour with the Willenhall locksmiths are less now than was universally the custom a few years ago. Since the opening of additional places of worship and the establishment of Sunday and day schools for the children of the working classes, and the gradual attainment of knowledge by the adult population, the operatives are not those drudges they were formerly. In proportion as they acquire useful knowledge, does the practice of long hours and excessive work lessen. Mr. Home, in the report before referred to, has drawn some very gloomy pictures of the moral condition of the locksmiths of Willenhall, but we are glad to state that since that period (1841) considerable improvements in this respect have taken place. The town also has much improved in its general appearance, as well as in a sanitary point of view. There are now both gas works and water works in full operation.

The following extracts will serve to give some idea of the social habits of these hard-worked and badly paid artisans:—

"Some years ago, a factor, who had projected a manufactory in Brussels, engaged some five-and twenty Willenhall men, whom he was at the expense of taking over. He gave them all work, and from hard-earned wages of from 9s. to last a week, these 'practiced hands' found themselves able to earn £3 a week and upwards. But they were not satisfied, and began to feel uncomfortable."

"First one left and returned home; then another, then one or two, till in the course of a few weeks every man had returned to Willenhall, resuming his slavery and his drunkenness, his low wages, dirty lanes, and destitution."

"About two O'clock on Saturday, some of those who did some work on Tuesday begin to appear in the streets; and large masses issue forth between four and five O'clock. The wives and elder girls go to market; the husbands and other adults to the beer-shops. By seven or eight O'clock the market is full; the streets are all alive; the beershops and gin-shops are full; and all the other shops are full. The [small] manufacturers are stretching their limbs, expanding their souls to the utmost, and spending their money as fast as they possibly can. No one ever thinks of saving a shilling."

We shall conclude this chapter by the following account of several small locks:—

Many minute locks and keys have been exhibited which are remarkable only for their smallness. Figure 465 represents a Barron's box lock and key, full size, made by Mr. Henry Yates. At the Exhibition of British Manufactures at Birmingham, in 1849, Mr. Chubb exhibited one of his patent detector locks, set in a gold finger-ring, the lock and key weighing but sixteen grains. At the Great Exhibition of 1851, Mr. Aubin exhibited a four-lever padlock 3/32 of all inch in diameter, or just small enough to go inside a hemp-seed husk. The key was a quarter of an inch long. The lock and key were made by two young boys, the sons of Mr. Aubin before named; but most of these locks are monstrously large in comparison with what were made nearly a century ago, as shown by the following extract from Shaw's History of Staffordshire:—

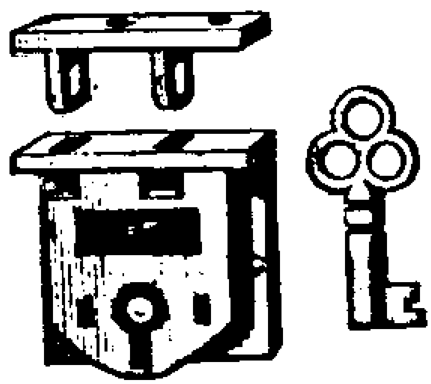

Figure 465

"June 13, 1776, James Lees, of Willenhall, aged 63 years and upwards, Showed me (Rev. T. Unett) a padlock, with its key, made by himself, that was not the weight of a silver two-pence. He at the same time showed me a lock that was not the weight of a silver penny; he was then making the key to it, all of iron. He said he would be bound to make a dozen locks, with their keys, that should not exceed the weight of a sixpence."

The illustration (figure **455**,) represents a Barron's portfolio lock made of a half-crown, and the hasp part of a four-penny piece, by Mr. Henry Yates, without at all injuring the faces of either coin by screws or rivets.

CHAPTER TWENTY-ONE: Useful Hints

in Connection with Iron Safes and Locks and Keys

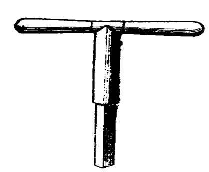
1. We have stated before when noticing the *detector* locks, that these locks will frequently detect themselves, and it often happens that in the carriage of iron safes which are fitted with detector locks, when they arrive at their destination, from the above cause, they cannot be opened. Therefore we would recommend all persons not to jump to the conclusion that the lock is spoiled, but to turn the key in the same direction as in locking, which will release the detector, then turn the key and unlock, when if the throwing of the detector has been the cause of the lock not answering to its key, it will at once open.

2. Under no circumstances use violence when a lock does not act properly. Violence will always do harm, whilst a little patience in "humouring" it will, in nine cases out of ten, enable the key rightly to perform its office. The majority of locks, if they are to go well, are like watches, they must have some degree of careful treatment. Instances are not uncommon of persons who have iron safes, in the possible event of the lock "taking to go wrong," putting an instrument (as a piece of iron) through the bow of the key to act as a powerful lever, hoping by such violent means to make the key unlock it. In such cases the words "open sessamee" would be far more likely to produce the desired effect. The result of such violence is that the key-bit breaks in the lock, and then there is no alternative but to drill or cut open the door, and in many cases the safe has to be sent to the maker to be opened and refitted, thus entailing on the owner a very considerable expense.

3. Others, under similar circumstances, fill the lock with oil; and if this happens to be at all glutinous, it sticks the levers (in the lock) together, in which case, whatever security the lock previously possessed, is by that means destroyed.

4. It must be remembered that the lock is the lightest and weakest part of an iron safe, and in its transit from one place to another the jerks or jars it meets with are quite sufficient to somewhat disorder the internal parts of the lock, but a sharp rap with a hammer on that part of the door immediately over the small lock, we have always found sufficient to set all right

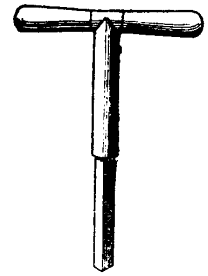
again.



5. In some locks containing a "curtain," the latter will sometimes get *over* the keyhole and thus prevent the key from entering the lock; but it is easily moved from before the keyhole into its proper position by means of the blade of a penknife or any other similar pointed instrument.

6. We recommend in all cases in locking and unlocking any lock, to remove the key after performing either operation.

7. In those safes where the large bolts are thrown by a knob or handle and secured by a small lock, it is a good plan to throw the bolts with a swing, for unless the bolts are thrown quite "home," the bolt of the small lock cannot enter the slot in the arm of the large bolts, by which all are secured. From not understanding the construction of the locks on the doors of iron safes, persons frequently attempt to lock the small lock without even turning the handle to first throw the large bolts, and the key is thereby sometimes broken.



8. When iron safes are made true and square, they require to be carefully fixed; and it is advisable to use a spirit level to set them, otherwise the doors will not open and shut freely, and in double-door safes the bolts of the locks cannot be thrown.

9. In double-door safes, first close the left-hand door, and then throw the bolts with the knob by turning it from right to left; then close the right-hand door, and throw the bolts of it by turning the handle *in the same direction,* then insert the key in the small lock, turn it round, and withdraw it; and to make sure that it is locked, try the handle of the right-hand door, as in unlocking. To open the safe, the same operation must be performed, but of course in the reverse order.

10. When safes are required to be sent abroad or removed from place to place, it is advisable to remove the handle and other *outside* fittings, placing them inside, and then with any square instrument which will answer the purpose of a spindle, or what is called a

answer the purpose of a spindle, or what is called a T-key (figure 466), throw the bolts, lock the small lock, and send the key by post or otherwise. We have adopted this plan for several years and have never had an accident, and it dispenses with the use of a packing-case. The *direction* or a piece of blank paper should be gummed or pasted over the key and spindle holes, to prevent dust or dirt getting either into the lock or into the interior of the safe.

Figure

11. In most small locks the main-bolt, even in brass ones, is usually made of iron, which in damp situations is sure to rust and will therefore *stick,* and when this is so, great care must be used to move it, otherwise the key-bit is apt to break in the lock. In consequence of this liability of the iron bolt to oxydise, we have for some time had all our locks constructed with *brass bolts,* and we recommend all lock-makers to use as little iron in the internal mechanism of their locks as possible.

12. Although it may be thought unnecessary, yet we must remind those who have iron safes to invariably have a duplicate key, which should not, as is so frequently the case, be placed *inside the safe,* but should be kept in some secret place, so that in the event of the other key being lost, the reserve key may be put in requisition to open the safe, when the combination of the lock can be altered, and new keys made at a trifling expenses so that, if the former key has dropped into improper hands, it would fail to open the safe. Instances have been of frequent occurrence where an individual has lost the one key, haling the other locked up in his safe, the result being, that *the door* has had to be cut or drilled open, and a new lock put on at a considerable cost.

13. We have before observed, and it may be well to repeat it here, that in fixing detector locks in which the detector has to be released by an *extra* shoot of the bolt, a space of from one-eighth to a quarter of an inch should always be allowed in the depth of the *bolt-hole* to allow for it, otherwise when the detector is thrown, and no play is left for the extra shoot, the lock cannot of course be unlocked.

14. Never leave your keys in the locks, or indeed out of your own hands. This precaution will effectually prevent a dishonest employed from taking an impression of them, or of tampering with them in any way, and for this reason use small or moderate sized locks with corresponding keys.

Several years ago a bank was robbed in America, and a clean sweep made of all the cash, although the iron safe was secured by an unpickable lock. On an enquiry being instituted, the manager recollected leaving the key in an unlocked wooden desk.

The great gold robbery from the South Eastern Railway Company in May, 1855, appears to have been consummated through an employed leaving the duplicate master key of the iron chest, whilst his back was turned only for a few minutes, in an unlocked repository. This circumstance suggests the propriety of using spring locks more generally so that all doors or drawers could be fastened in an instant merely by closing them. This robbery has proved beyond all question the possibility of making a key that will open a Chubb lock, by simply taking an impression of the original; and we now think it necessary still further to caution all persons against carelessly leaving their keys in a public or in an unsafe depository. The composition used for the purpose of taking impressions is composed of bees' wax, powdered charcoal, and oil; and a sufficiently accurate impression can be thus obtained of the key of almost every patent lock made, from which a perfect key can be fabricated.

We should recommend all such specie chests for regular transit between one place and another to be secured by two or even three locks, each lock in its construction to be as dissimilar from the others as possible, as well as the keys. Had this plan been adopted, this robbery could not have been effected by the means stated to have been employed in the evidence taken before the Lord Mayor, at the Mansion House London, in November, 1856.

15. Pipe keys should occasionally be examined, and any foreign matter that may have got inside the pipe or drill-hole should be removed.

16. Should the levers in lever locks be found to "grate" or to make a whistling noise when in action, take a fine needle and dip it in olive or best sweet oil, and with it touch very slightly all the long steps of the key-bit, and then apply the key to the lock in the usual way; such grating is caused by the springs being made unnecessarily strong. The short steps seldom or never require any oil, as the lifts of these levers being short, produce but little friction.

17. In ordering cabinet furniture, be particular in stipulating that a certain quality of lock shall be used, as it is the custom both with first-class as well as inferior makers to use inferior

or common locks. We would recommend architects also in their specifications to name particularly the quality of locks to be employed, whether warded locks, lever locks, &c.; and if the latter, how many levers the lock is to contain.

18. As most of the traveling and writing cases, despatch boxes, &c. sold are fitted with common locks, many of which, as we have stated before, can be readily picked by a quill, we strongly recommend commercial travelers and others who use such articles to satisfy themselves of the real quality and security of the locks before entrusting cash or private papers to their custody.

19. Some makers call an iron doors and frames fire-proof, whereas in some there is no fire-proof composition in their construction, therefore architects should always specify that the back of the lock-chamber should contain a certain thickness of composition. We know of several instances where one maker has estimated for a genuine fire-proof door, and the order has been given to another maker, because his estimate was some little lower; but when the door came to hand, it was found to be of the former kind, i.e., without any fire-proof composition at all in its construction. The difference in price between a fire-proof door and one not fire-proof is from two to five pounds, according to the size of the door.

20. The bolt of a right-hand lock always shoots from left to right, and a left-hand lock from right to left, *as you stand on the* OUTSIDE *of the door.* Mistakes with respect to the *hand* of locks are of daily occurrence. What the carpenter calls a *right-hand* lock, the locksmith calls a *left-hand,* and *vice versa.* In order to prevent such mistakes in future, we have thought it as well to illustrate the difference by the following diagrams represents a door which would require a right-hand lock. Figure 468 represents a door which would require a left-hand lock.

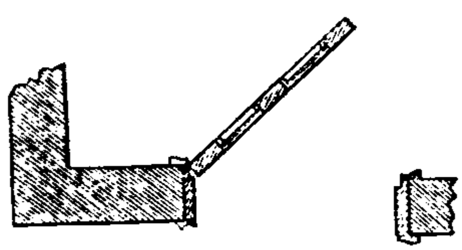


Figure 467. This door requires a *right* hand rim or mortise lock.

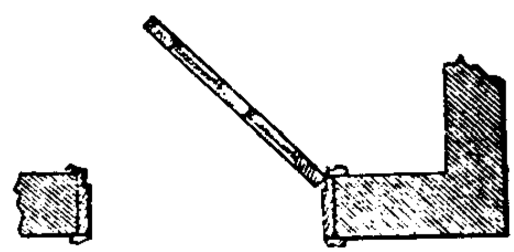

Figure *468. This* door requires a *left* hand rim or mortise lock.

Figure 469 represents a pair of folding cupboard, book-case, or

wardrobe doors, which would require a left-hand lock. Figure 470 represents a cupboard with a single door, which would require a right-hand lock. By observing these figures the reader will perceive that the hand is found by standing on the *outside* of the door, and locking the lock by turning the key in the right-hand locks to the right, and in the left-hand locks to the left; if the bolt comes out to the left it is a left-hand lock; if to the right it is a right-hand lock. This is the locksmiths' rule. We recommend all parties when ordering such locks to give a sketch of the previous figures, or quote the number of the particular figure or figures before described.

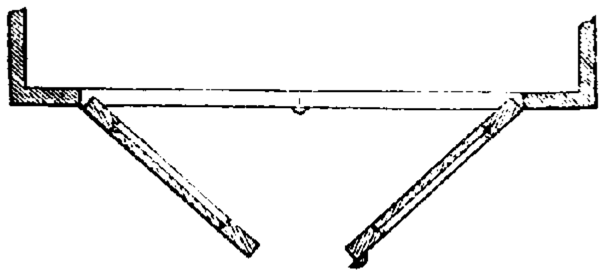

Figure 469 Pair of folding cupboard, book-case, or wardrobe doors, which require a left-hand lock.

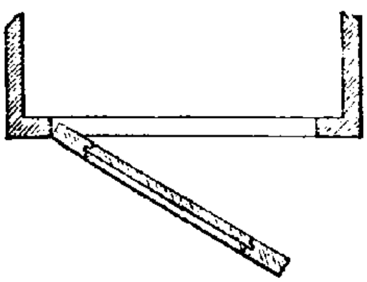

Figure 470 Single cupboard door which requires a right-hand lock.

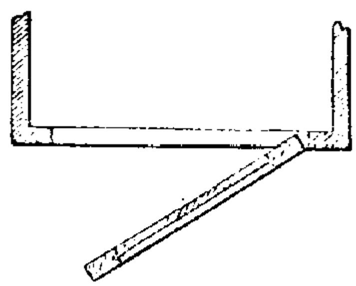

Figure 471 Single cupboard door which requires a left-hand lock.

It may be well to notice that for a closet in a room in which the door of the closet is constructed to pull *towards you,* if a rim lock be required to be fixed on such a door so as to be *inside* the closet when the door is closed, the bolt of the lock or latch would require to be bevelled just the contrary way to the ordinary locks, as in closing the door you push the lock away from you, instead of pulling it towards you. Such a lock is called by locksmiths a reverse-bolt lock, and it requires to be fitted with a striking-plate for the door-case instead of the ordinary box-staple of the other locks.

21. The length and width of the lock required (if of importance)

together with the thickness of the door should always be given in ordering any door lock.

22. If the knob or the keyhole are required to be any particular distance from the edge of the door, always measure from the centre of the spindle hole and the centre of the keyhole respectively.

23. In ordering locks never run down the price, because whatever reduction you may get from the regular end fair prices, is certain to be made out to you in so much less security, so much less strength, and so much less finish. By the adoption of such a system, however much you may think you have saved, the maker will have got more, as there is always more profit, in proportion, attending the manufacture of a common article, than one of a superior quality.

24. Before purchasing either an iron safe or a lock, we recommend buyers to compare the productions of one maker with those of another, examine their several merits and judge for themselves. It is to assist them in this object that this work has been published. Let them not be entrapped by the present unscrupulous means adopted by some persons to increase their business. Even the *professors* of religious truth in these days are guilty of conduct most reprehensible in this respect. The old proverb "let everything stand on its own bottom," seems to be altogether ignored. One manufacturer thinks no means too unworthy or disreputable to employ to raise his own wares and to lower those of his competitors in the estimation of the public. Another by the most unblushing falsehoods in the shape of puffing advertisements seeks thus to increase his business. Another knowing the credulity of the general public, seeks to produce an impression on their minds of the vastness of his establishment, by exhibiting and publishing drawings of manufactories or shops that never had an existence, or the true buildings so increased in size, in number, or in the accessories to complete the picture, that the original is altogether lost in the supposed representation.

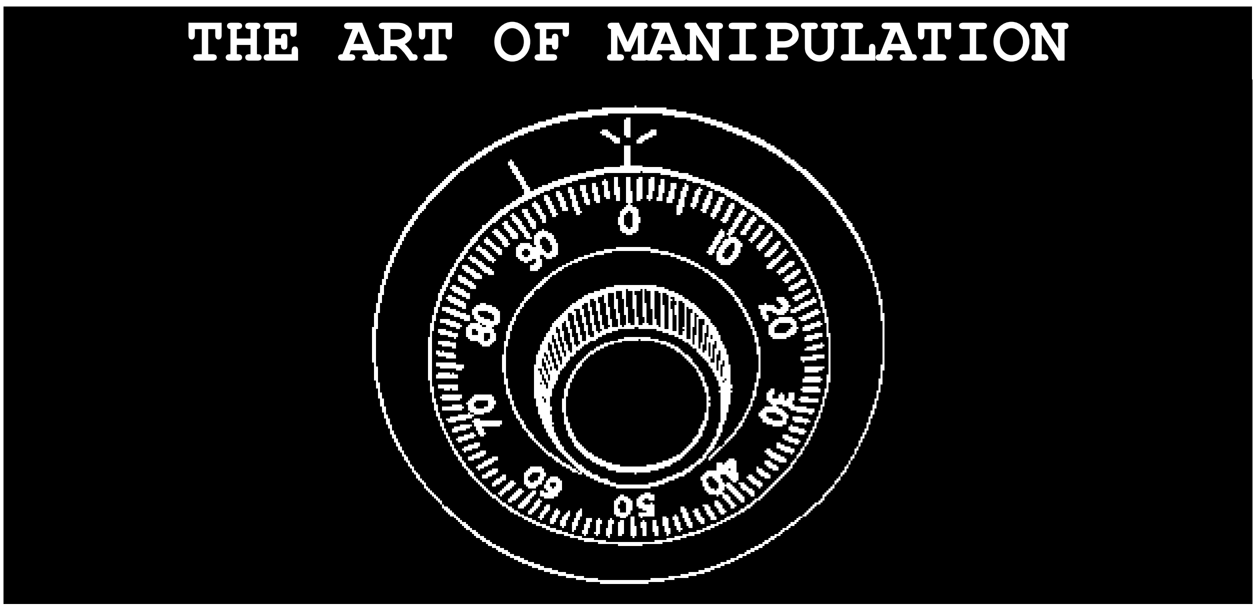
25. Many robberies take place through the want of due care with respect to cash boxes and other portable depositories. The former useful articles, even when containing convertible property of great value, are frequently locked up at night in a wooden desk or cupboard. A few weeks ago we read an account of the robbery of a cash box from a carrying firm at Bradford. The thieves had only to prize open the lid of the desk, and there was the cash box

containing about £40 with which they got clear off. Another careless practice is, to have the cash box lying about the counting-house or office. The following robberies which occurred lately will show the necessity of either keeping such valuable property in the drawer of an iron safe, or locking-up the cash box in one. Robberies similar to the above are of almost every day occurrence; and yet although the accounts of them appear in the newspapers, few take warning, till they have been taught the necessity of it by dear experience. When the horse is stolen, the stable door is locked.

The latter remark applies quite as much in respect to the carelessness manifested by many persons in reference to the preservation of books and papers from fire. In colliery offices, many of which are mere hovels, the books are almost invariably kept in wooden receptacles, amongst all sorts of articles used in the colliery, some of which as cotton waste, oil, &e., are calculated to cause spontaneous combustion. Last year a fire took place in an office of this description, in the neighbourhood of Willenhall, which of course consumed the wooden desk and the books it contained. We need not say, that after the books were thus destroyed, the proprietors of the colliery purchased an expensive fire-proof safe, whereas, had they expended but half the amount previously in a safe receptacle for their books, they would have saved some scores of pounds, as they had to trust to the honor of their customers as to what amounts they respectively owed them.

"DARING HOUSE ROBBERY AT CAMP HILL. On Sunday evening last, a daring robbery was effected in the house occupied by Mr. Foster, Trinity Place, Camp Hill. The thieves, taking advantage of the temporary absence of the inmates at Church, comparative seclusion of the locality, broke into the premises by means of *skeleton* keys, and making, as it would appear, direct to the bed room, carried off a *cash* box containing £5 and £10 notes on the Coventry Bank, to the amount of £80; also a gold watch, seals, and key, a silver snuff box, a gold ring, purse, silver toothpick, and other valuable trifles, amounting with the notes, to about £105. The cash box was found early on the following morning, empty, of course, in an entry in Hill Street; but the thieves have not yet been traced by the police. It is to be hoped that this notice may serve as a caution to householders, many of whom, notwithstanding the frequent instances of housebreaking during Church time on Sabbath evenings, leave their premises not only unwatched, but in many cases entirely unsecured."

Aris's *Birmingham Gazette.*



"Thirty Thousand Pounds stolen. Early on Friday morning, as one of the Borough Constables of Sunderland was patrolling his beat, be observed two young boys endeavouring to avoid him, upon which be crossed the street to see what they were about. They at once ran off but the officer succeeded in taking one of them into custody, who confessed that be and his companion bad just broken into the counting-room of Mr. J. H. Brown, rope manufacturer, and stolen a *cash* box, the contents of which were of great value. The boy who escaped, he said, had the box with him and the officer having ascertained the address of the fugitive, apprehended him, also in a few hours, and ascertained from him that be had buried the box in the Town Moor. The spot indicated was then dug up, and the box found; and on its contents being reckoned up, they were found to amount to £87 in cash, and £2,460 in cheques and bills. The boy who was first taken into custody was employed in Mr. Brown's office, and on Saturday he confessed to robbing his master of a £50 note about six weeks ego."

Manchester Guardian.

"A daring robbery was effected at the shop of Mr. Sotheron, bookseller, York, on Friday se'nnight. During the dinner hour of the assistants and the errand boy, two respectably dressed men entered the shop and requested to be shown certain articles. Mr. Sotheron was in attendance, and produced several books, but one of the men particularly wished to see a 'History of the Bible,' which was lying in the window. To obtain this Mr. Sotheron had to open a folding sash, one side of which was covered with prints, and which when thrown back concealed part of the shop from his view. Under the pretext of facilitating the search, the taller of the men went outside the shop, and pointed through the window to the book in question, as well as to another which he pretended to want. In the meantime his accomplice went into the counting-house behind the shop, and stole Mr. Sotheron's cash box, containing a quantity of gold and silver (including a double sovereign of the reign of George IV.), a promissory note for £200, a £10 Bank of England note, a £5 ditto, several York and West Riding notes, two bankers' deposit notes for £50 each, some bankers' receipts for railway cars, and other documents. The books pointed out having at length been found, the man who had stolen the cash told his companion that he should walk on, and accordingly left the shop, The other fellow requested Mr. Sotheron to make a neat parcel of the books he had selected, and promised to call for it in about an hour. Nothing more, however, was seen of him by Mr. Sotheron, who in the course of the afternoon went to his desk for the cash box, and found it was gone. The thieves have not been detected."

Aris's *Birmingham Gazette, November* 10th, 1856.

In closing this chapter, we would beg to draw especial attention to a little pamphlet by Mr. George Cruikshank entitled "Stop Thief," in which he suggests some most excellent and innexpensive concontrivances for securing doors and windows against burglars. The house-breakers' implements and method of breaking in are also explained, in order to give the house-keeper a through knowledge of the plan of attack, so that he may apply such fastenings as may frustrate the operation of the thief.

Clyde Lentz and Bill Kenton
First Edition, 1955

Introduction to Second Edition.

The original printing of ***The Art of Manipulation*** was in 1955. Although small in size, it was the first printed work to detail and describe the step by step theory and process of manipulation by practitioners in the trade. I think it is fair to say that the manual has been purchased by almost every safe and vault technician, since its original printing.

Because of its longevity and wide acceptance, it has been included within **LSS+**, as an added reference to the materials

presented in **Chapter 36.** The text and graphics have been edited and revised by the author to enhance understanding of the material. The basic concepts, however, have not changed, although the design of some Group 1 and Group 2 locks certainly have been altered and improved.

When Kenton and Lentz (referred to as "the authors") first published their manual, computer-based systems were not even a dream. Thus, the X-07, X-08, and competing products were not even contemplated. There were no robot dialers or other sophisticated forms of manipulation machines. Microprocessors had not been invented, nor the advanced devices that exist today to open combination locks.

It is hoped that the revision of the original edition provides an enhanced understanding of the subject, and offers another perspective to the Art of Manipulation.

MWT

MASTER EXHIBIT SUMMARY

CHAPTER ONE: Introduction to Manipulation

This chapter introduces the reader to manipulation, providing a summary of how and why locks can be opened by touch, feel, and sound. Specific definitions, the jargon of manipulation, are also presented. The reader is directed to Chapter 36 of Locks, Safes, and Security for a more thorough treatment of the subject.

DEFINITION of Manipulation

MANIPULATION is the art of opening combination locks:

- ***Without prior knowledge or information as to the present combination;***
- ***Does not require the use of force or tools;***
- ***Does not cause damage to any part or component; and leaves no evidence of entry.***

The technician learns:

- **To move each wheel in order to indicate their position in relation to the fence;**
- **To determine the relationship between wheels, gates, and fence by sight, Sound, and feel;**
- **To utilize electronic or mechanical devices as an aid to manipulation; however, they are not necessary but in some cases may be beneficial.**

NOMENCLATURE OF COMPONENTS

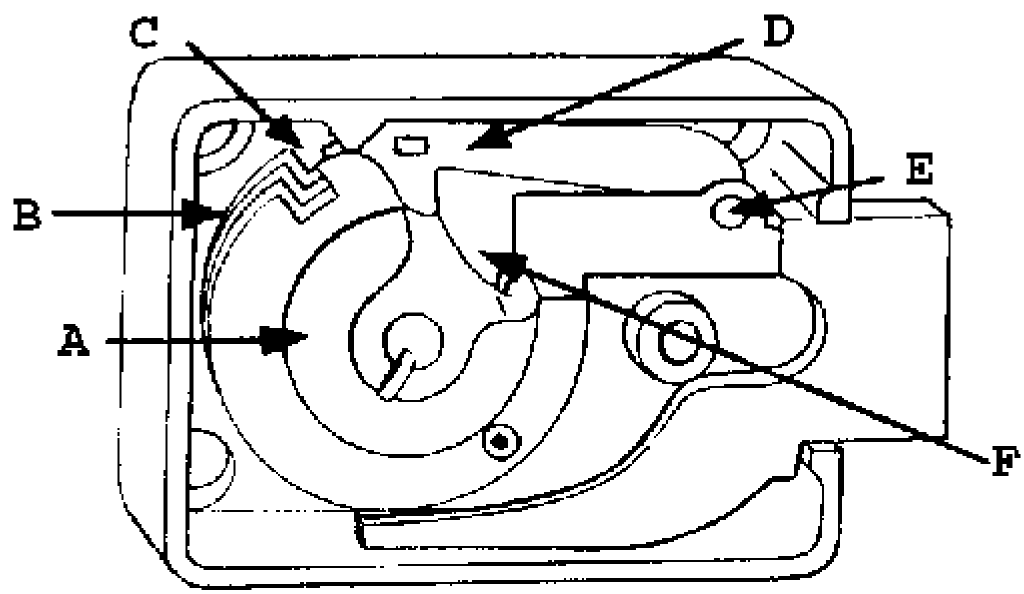


Figure M01 (A) drive cam, (B) tumblers or wheels, (C) wheel gatings, (D) lever fence, (E) lever screw or pin, (F) drive cam opening.

Why Manipulation Is Possible

There are eight primary conditions resulting from manufacturing tolerance errors that permit manipulation:

1. Differences in widths of gating in each individual wheel and in the drive cam;

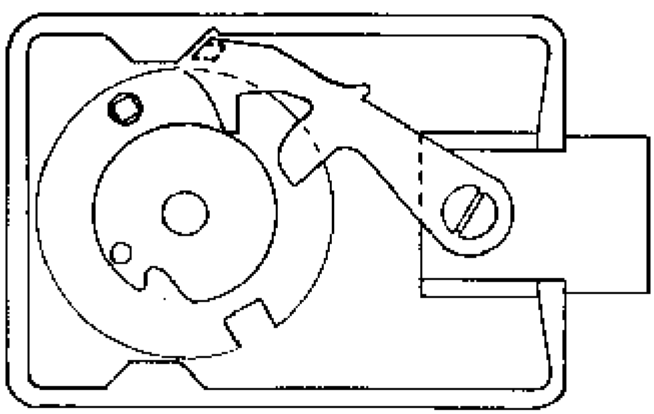
2. Variations in the wheel post diameter for each wheel;

3. Eccentricity of each of the wheels;

4. General inaccuracy in and failure to maintain tolerances in the manufacturing process.

In machine-produced parts there must be a certain degree of tolerance or clearances for the proper movement and functioning of components. The same requirements exist for traditional key locks, and forms the basis of picking and impressioning theory. For example, the inside diameter of the wheels must be approximately .005” larger than the wheel post to allow free

rotation on the post.



5.Differences in distance between nose of the lever and fence. The picking and decoding of lever locks closely parallels this parameter.

6.Differences in the diameter of the drive cam.

7.Squareness in wheel gatings and mating fence.

8.Tolerances in the lever Fence locks. The lever is secured to the bolt by a screw or pin, and in some locks is equipped with a lever spring, so that the lock can be mounted in different positions (Vertical up, Vertical down, Right or Left hand.) In order for the lever to work freely on the bolt screw or pin, the inside diameter of the hole in the lever must be considerably larger than the outside diameter of the actual bolt screw or pin.

The requirement for this tolerance can be understood from the illustration; Note how the play between lever and bolt creates a different position of the fence.

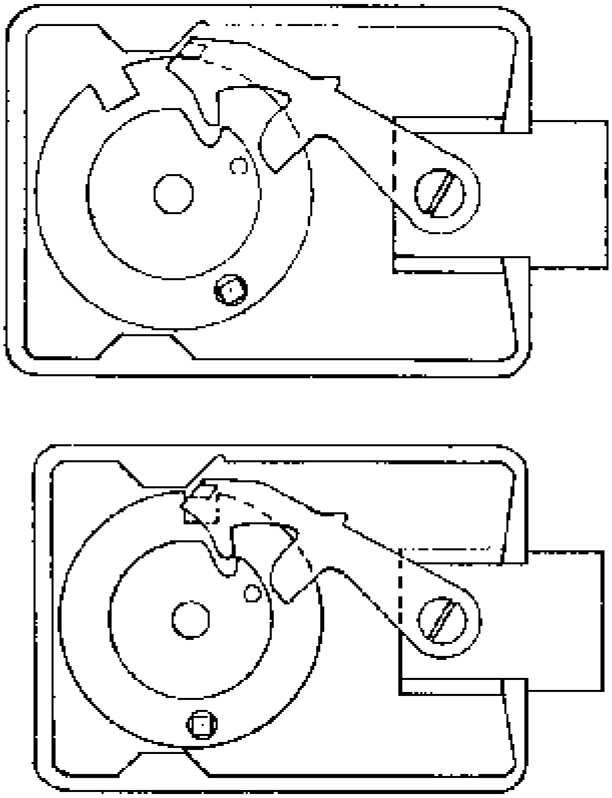


Figure M02. These diagrams demonstrate the different positions of the fence and nose of the lever during the manipulation process. In (top left), the fence and nose ride on the drive cam. In (top right) the fence is resting on the wheels with the nose of the lever in the drive cam opening. In (bottom), with No. 3 wheel-gating lined up with the fence and lever nose in the drive cam opening, the fence rests on No. 1 and No. 2 wheels, allowing the fence to tilt into the gating of No. 1 wheel and the nose of the lever to drop further into the drive cam opening.

A better understanding of the following procedures can be achieved by mounting a three-wheel lever fence lock, such as the S&G 6730, so that it may be manipulated throughout the remainder of this text. Cutaway locks may also be purchased from Lockmasters, MBA, and other vendors. After mastering the concepts to allow successful manipulation of the S&G lever fence design, it is suggested that similar products of different manufacturers and different basic designs be utilized.

Later in the text, variations upon the technique of manipulation will be explained, for different basic lock designs. Although there is a variance in procedures resulting from mechanical designs, the fundamental theory of all manipulation remains

constant.

Categories of Locks that are Subject to Manipulation

The authors have identified six primary classifications of combination locks that can be manipulated within the Group 2, or unlisted categories. Opening procedures vary according to each category, and are described in the chapters that follow.

- ***Gear-driven rotary fence***
- ***Rotary fence, spring-actuated***
- ***Lever fence***
- ***Straight tail-piece***
- ***Bottom drop***
- ***Off-set gear driven***

CHAPTER TWO: Manipulation Procedures for Lever Fence Lock

Introduction

The worldwide prevalence and acceptance of the lever fence combination lock makes this mechanical configuration the obvious choice for use as a model for teaching manipulation within this text. Variances in opening procedures for the other forms of locks previously identified are described in later chapters.

Manipulation Procedures for Lever Fence

There are two contact points in this mechanical configuration, and as with the Rotary fence lock, the sloping side of the drive cam provides a better indication of each wheel. Because the lever fence is so popular, detailed information will be provided as to the procedures that should be employed for a successful opening.

Overview of the Manipulation process

In order to determine the combination for a lever fence lock, the following critical actions must be accomplished:

Step 1: Determine the total number of wheels

Step 2: Determine the location of the contact points
Step 3: Find the low area of each wheel
Step 4: Determine which wheel is indicating

Detailed Manipulation Procedure

Each of the following steps must be successfully completed in sequence.

STEP 1: Determine the number of wheels in the Wheel Pack

It is critical to determine the number of wheels or tumblers within the lock to be opened. Obviously, if only three wheels of a four-wheel mechanism are tested, success can never be achieved. This information can also become invaluable for service calls where a mechanical malfunction has developed, such as stuck flys, tumblers sticking together, loose back plate screws, and other problems.

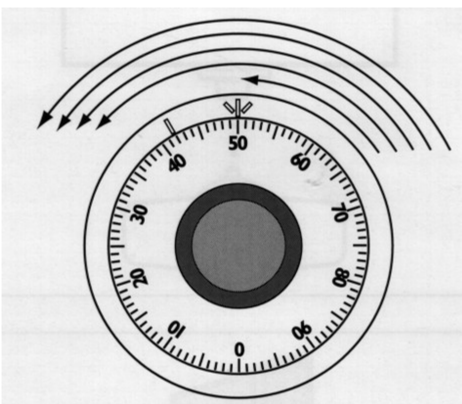

Figure M03. All wheels are rotated in one direction several complete revolutions, in order to insure th wheels are picked up.

In order to determine the number of wheels, all of the discs are rotated in one direction for several revolutions, so that all of the flys and drive pins are engaged, and all of the wheels within the wheel pack are rotated together. Direction of rotation is then reversed, so that an accurate count can be made as each wheel is picked up in succession.

Detailed Procedure for Counting Wheels

- **Turn the dial to the right (clockwise) six times stopping on 60;**

- **Turn left (counterclockwise) slowly to 50 then rapidly continue left past 60, listening and feeling as the wheel closest to drive cam is picked up. One wheel has now been counted;**

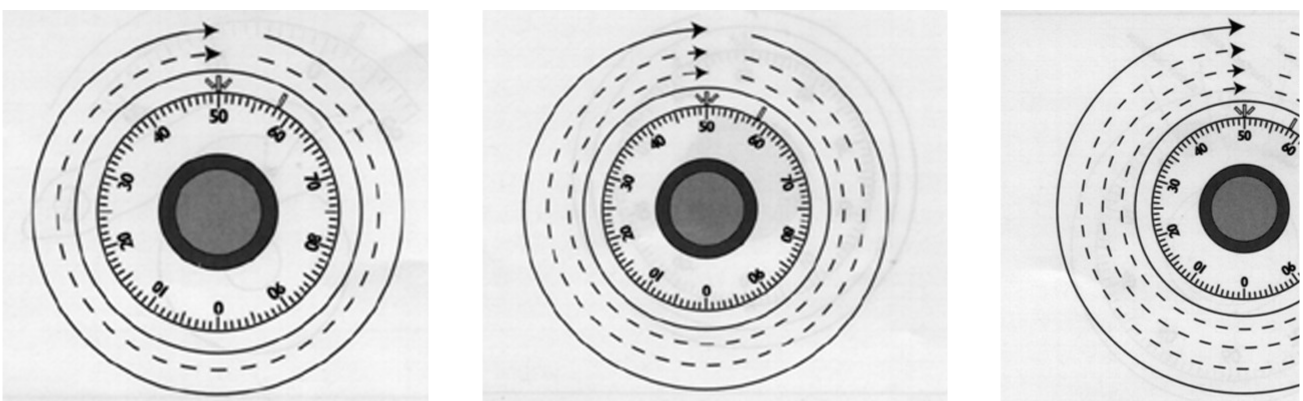
- **Continue turning left to 50 then rapidly past 60, listening and feeling as the next wheel is picked up. The count is now two wheels;**

- **Continue turning left to 50, then rapidly past 60, listening and feeling, as you pick up the next wheel. Three wheels have now been counted;**

- **Continue turning left to 50, then rapidly past 60, listening and feeling for an additional wheel. At this point, if there was no indication of another wheel, the lock only contains three discs.**

- **If an indication of a fourth wheel was received, then the lock must be tested for a fifth wheel;**

- **Continue turning left to 50 then rapidly past 60, listening and feeling as another wheel is tested. If so, then the lock contains five wheels within the wheel pack.**



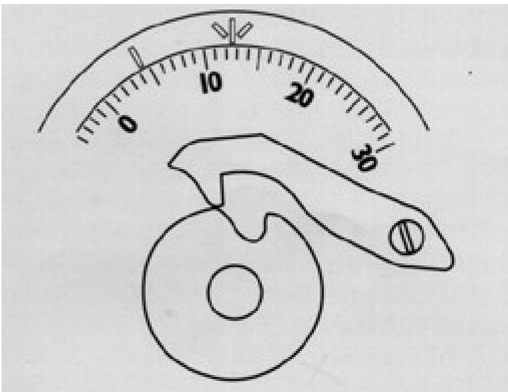


Figure M04. After parking, wheels are rotated so that each complete turn picks up another disc.

STEP 2: Determining the Location of the Contact Points

This is probably the most critical function to perform, because

it will provide you with the data (readings) from which all manipulation theory is based, and which is required to allow graphing of the geometry of each wheel. From the contact readings, the low areas for each disc can be determined, and ultimately, the gate position for each wheel is correlated.

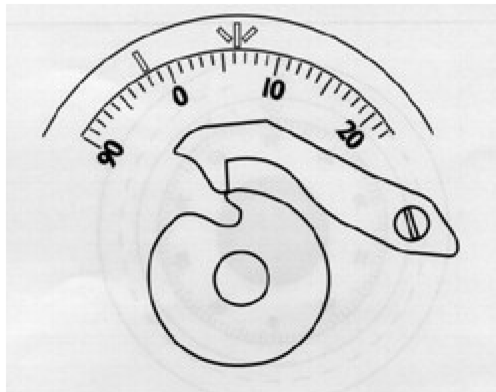

Figure M05. Contact points are shown for left (12.2) and right (8.1)

Detailed Procedure to Locate Contact Points for Lever Fence

Rotate the dial four times to Right, stopping at 60 (five times on a four wheel lock), turn left and attempt to feel and hear when the lever touches each side of the gateway of the drive cam.

Do this by oscillating over an area of approximately ten numbers at a time until you have determined the precise location of the two contact points. The **drop in area** is equivalent to locating each side of the drive cam opening or drop in point.

After finding the two contact points, lightly grasp the dial between thumb and forefinger and rotate the dial lightly between the contact points and note the exact location on the dial where the lever contacts the drive cam on the left and right side.

In the case of our test lock (using the sloping side on the drive cam), the contact point reads 12; the sharp side of the gate will provide a contact reading of 2. If the number-three wheel is lined up with the fence, and the **right** contact is read, then the fence reading improves as the nose of the lever drops further into the drive cam opening. In this event, the reading will be closer to 11.

Locating Contact Points for Spring Actuated Rotary Fence Lock

In the spring-actuated rotary fence lock, the fence is mounted on

a post secured to the lock case. In order for the fence to move freely on the post, it must have a considerable amount of tolerance. This type of mechanism will react in the same way as the lever fence, during manipulation.

Readings and contact indications can only be obtained when the dial is rotated to the left, because of the mechanical design of this category of lock. This results from a design that allows the fence to touch the drive cam only when it is rotated in the counterclockwise direction.

Locating Contact Points for Gear Driven Rotary Fence Lock

The fence in this lock works in conjunction with a gear, which in turn is actuated by the drive cam. This design differs from the spring-actuated mechanism because the fence only touches the drive cam when rotating the dial to the left; thus, there is only one contact point.

Determine which of the two contact points is to be used to obtain indications or readings on the dial. In some cases it is better to use the sloping side (right contact) of the drive cam opening because it will give a better indication when a wheel gating lines up with the fence. In other cases it makes no difference which contact point is selected, because the drive cam opening has the same contour on either side.

STEP 3: Finding Low Areas of each Wheel

The essence of successful manipulation is the determination of the lowest spot on each wheel, which must correlate to the position of the gating. Throughout the process, the goal is to cause the fence to drop further and further into the wheel pack. This is based upon the assumption that the lowest spot may be either a wheel gating or a dip in the edge of the wheel geometry that will allow the fence to contact the edge of the next lowest wheel. *The critical requirement, then, is to keep working toward the lowest spot within the wheel pack at all times.*

As the surface of each wheel is tested for each dial division or group of divisions, the contact readings are charted or graphed in order to provide a true representation of the geometry of the precise circumference of each disc. When all of the wheels have been graphed, a correlation can be made as to the location of each gate, and the combination is thus derived.

Documenting Contact Readings

Illustration graphs are provided for a three-wheel lever fence lock. Standard graph paper or preprinted forms from Lockmasters or other vendors can be utilized. Although some safe and vault technicians do not often chart their readings due to the time required, the practice is in large measure dependent upon the type of lock, and its tolerances. Students should chart all readings until proficiency is achieved.

Charting Procedure

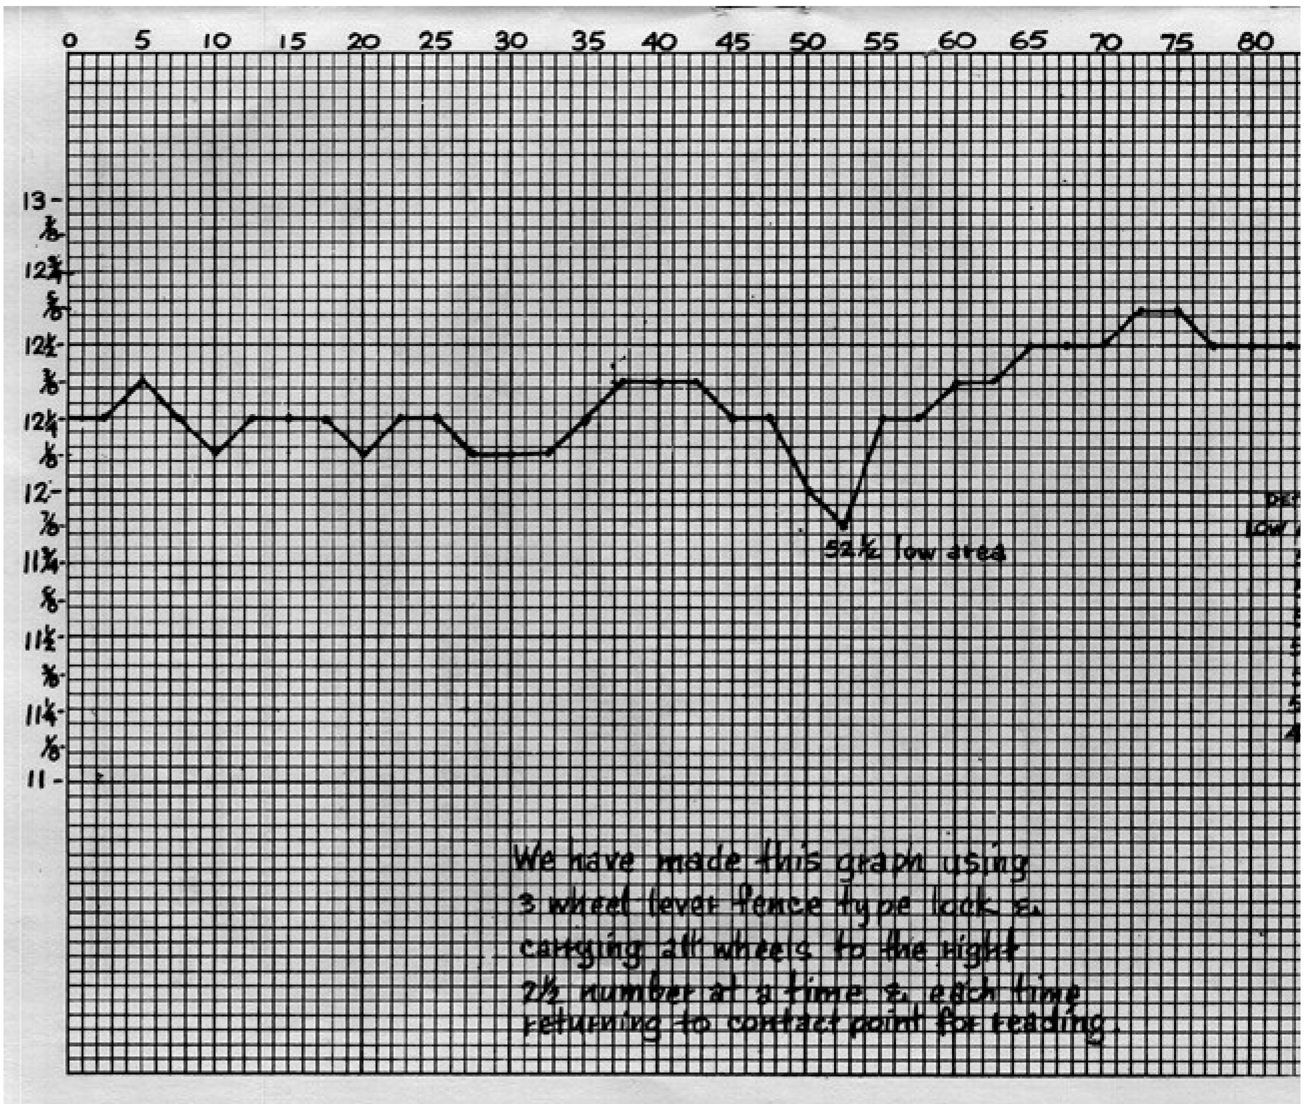

Figure M06. Graph #1

Turn the dial four times right, carrying all wheels to “0”. Turn the dial left to the contact point. It is important to grasp the dial with a very light touch when turning to a contact point. This is a critical issue, because the validity of the reading depends upon the nose of the lever barely touching the gate area. If the nose is over-driven, then the reading will be skewed and in error. Remember, manipulation is based upon tolerance errors of a few thousandths of an inch. This correlates to an extremely minute change within the dial marker indication as the relative location of the nose within the lever changes.

- **Turn dial to the right, moving all wheels to 97 1/2;**
- **Turn dial to the left to contact point, take reading, and record on graph;**
- **Turn the dial to the right, moving all wheels to 95;**
- **Turn the dial left to contact point, take reading and record on graph;**
- **Turn the dial to the right, moving all wheels to 92 1/2;**
- **Turn the dial left to contact point, take reading and record on graph;**
- **Turn the dial to the right, moving all wheels to 90;**
- **Turn the dial left to contact point, take reading and record on graph;**
- **Turn the dial right, moving all wheels to 871/2,**
- **Turn dial left to contact point, take reading and record on graph.**
- **Before taking each reading at the contact point, oscillate the dial right and left over the drive cam opening, in order to float or work the fence to the lowest possible point. This will give you a closer reading.**

Follow the above procedure for every 2.5 number divisions, moving all wheels completely around the dial, taking readings and making

recordings on the graph.

The number of divisions for each sample is in part based upon the tolerance of the lock and the interaction of the gate and fence. A contact reading may be taken every number, if desired. This will provide more qualitative data from which to chart wheel geometry. However, every 2, or 2.5 division is sufficient for most Group 2 locks.

In the first edition of this manual, the authors did not address the issue of “parking” of each wheel during contact readings. This concept is important, and is addressed more fully in **Chapter 36** of Locks, Safes, and Security. Parking describes the practice of isolating each wheel, so that a determination can be made as to which is indicating. This is required in order to derive the correct combination sequence, and to insure that only one wheel is analyzed at any one time.

Parking simply requires that the first, second, or third wheel (in a three wheel lock) is rotated through the contact area, while the other wheels remain in one position. This is accomplished at the beginning of the reading sequence, when all wheels are rotated left or right to pick up all flys and drive pins. Depending upon which wheel is to be tested, the **first**, or **first and second** wheels are set to an imaginary number on the dial.

If the first wheel is to be tested, then after all wheels are rotated left for several revolutions, the dial is turned right, for example, to take contact readings. If the second wheel is to be tested, then after AWR or AWL, the first wheel is set to an imaginary number as if the combination were being entered. The rotation direction of the dial is reversed and the second wheel is moved through the contact area, division by division. If the third number is to be tested, then this process is repeated as if the first and second imaginary numbers were dialed; the third number being tested for contact readings. In this manner, each of the wheels can be tested individually.

Remember that as the wheels are moved to the right and pass the contact point, there is only a short rotational clearance remaining to the other contact point in order to take reading. Do not rotate completely around the dial. To illustrate, our contact point is approximately 12, so as we pass 12 and go to 10 with all wheels, we only turn back left two divisions to the contact point to obtain a reading.

When finished taking samples of each dial division group, examine graph for:

Sharp drops and rises
Gradual drops or rises

Identify all apparent low areas on the graph. These indications represent **potential** gate areas on each wheel, although they may also represent production errors in the stamping of each disc. It must also be understood that a failure to identify a low area may be due to a problem known as shadowing, whereby an adjacent wheel is blocking a reading of the next gate.

In our example graph, the *apparent* location of the gate is at 52. However, this is not a precise measurement but rather an approximation. The exact drop in point must now be determined.

Finding Exact Drop In Point

This is accomplished by first rotating the dial four times right, stopping at 56. Then,

- **Turn the dial left to contact point and record reading;**
- **Turn the dial right, moving all wheels from 56 to 55;**
- **Turn the dial left to contact point and record reading;**
- **Continue every number to 49, each time moving the wheels only one division at a time, and record the readings.**
- **By checking recordings, we find 52 gives the best reading or indication, so we assume 52 is one of the combination settings.**

The use of graphs in learning manipulation is most important, and the authors advise making a graph on every lock that is manipulated until proficiency is achieved. A graph will provide an overall picture of low areas of the wheel pack and in some cases will indicate two numbers of the combination setting.

Always study your graphs thoroughly, not only for sharp declines which likely indicate a gate, but also for gradual declines over

several numbers. Occasionally, a sharp decline will not be recorded; therefore the number-one and number-two wheels will have to be set in this gradual low area, and then attempt to obtain a better reading or indication of the number-three wheel.

To illustrate, assume that the gradual low area is between 37 and 52. The authors outline the following procedure to determine the precise location of the gate:

- **Turn the dial right four times, stopping at the center of the low area (approximately 43);**
- **Turn the dial left one complete revolution, picking up the number-three wheel at 43 and stop at 45;**
- **Turn the dial right to the contact point, take reading and record them on the graph;**
- **Turn the dial left to 45, picking up the number-three wheel and stop at 47;**
- **Turn the dial right to the contact point, take a reading and record it on the graph. Continue moving the number-three wheel every two divisions (numbers) completely around the dial; Determine which wheel is giving the lowest reading or best indication. By the process of elimination, find which wheel is giving the low or best indication;**
- **Turn the dial to the right four times, stopping at 52;**
- **Turn the dial left, causing only the drive cam to rotate. No discs are affected until reaching 52, where the number-three wheel (the one closest to the drive cam) is picked up. Stop at 62;**
- **Turn the dial right to the contact point and take a reading. At this time, the number-one and number-two wheels are at 52 the number-three wheel is on 62.**
- **If a good reading or indication is lost, it is likely that the number-three tumbler is the one that is giving the good reading. If there is still a good indication, then rotate the dial left to 62, picking up the number-three wheel; continue**

left and pick up number-two wheel at 52 and stop at 62.

- **Rotate the dial right to the contact point and take a reading. If a good reading or indication is lost, it is probable that the number-two tumbler is the one providing the good reading or indication. If there is still a good indication, then the number-one wheel must be the one being tested.**

This process is a modified form of "parking" which was noted earlier. Its purpose is to isolate and identify the indicating wheel, by eliminating the other two (or three) tumblers during the taking of readings.

We are actually moving one wheel at a time off the number that is giving the best indication, beginning with the disc that is nearest to the drive cam, or the number-three wheel in a three wheel lock (number-four wheel in a four wheel mechanism). Assuming that the number-three wheel was actually the one giving the good indication, we know that the third number of our combination is 52.

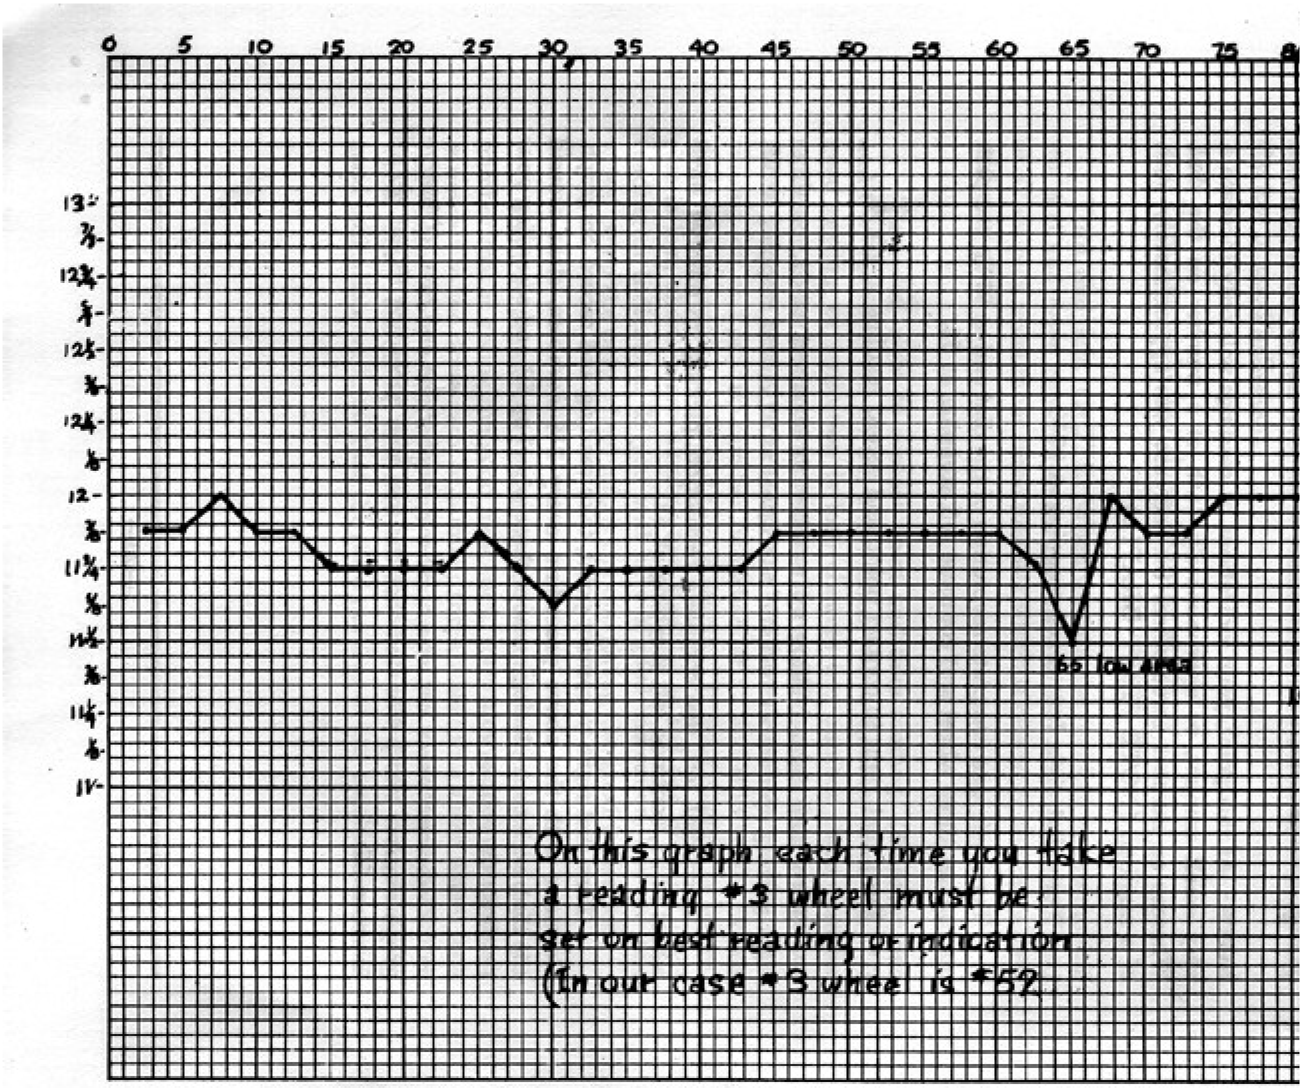

Figure M07. Graph #2.

- **Determine the low area or drop in point of tumblers number-one or two. A graph should be prepared for readings of these wheels;**

- **At this point, the indications or readings will increase a very small distance; approximately 1/8th of a dial marker division. In contrast, the change in the number-three wheel indication was approximately 1/4th of a marker division. Refer to the first graph;**

- **Turn the dial right four times, stopping at 97 1/2;**

- **Turn to the left one complete revolution, picking up the number-three wheel at 97 1/2, continuing left and stopping at 52;**

- **Turn the dial right to the contact point and record the reading on the graph;**

- **Turn the dial right, picking up the number-three wheel at 52;**

- **Continue right while picking up the number-two and number-one wheel at 97 1/2 and stopping at 95;**

- **Turn the dial left for one complete revolution, picking up number-three wheel at 95. Continue left, stopping at 52;**

- **Turn the dial right to the contact point, take a reading and record on the graph. Continue to take samples for every 2 1/2 numbers, completely around the dial. For each reading, place the number-three wheel on 52 and record the readings;**

- **Determine the exact low area of wheel number-one and number-two, by examining the second graph. We find that it is probably at about 65;**

- **Turn the dial right four times, stopping at 68;**

- **Turn the dial to the left one complete revolution, picking up number-three wheel at 68, and stopping at 52;**

- **Turn the dial right to the contact point, take a reading and record it;**

- **Turn the dial to the right and pick up the number-three wheel at 52, then continue right, picking up the number-one and number-two wheels at 68, stopping at 67;**

- **Turn to the left one complete revolution, picking up the number-three wheel at 67, continuing left and stopping at 52;**

- **Turn right to the contact point, take a reading and record the**

data Continue moving the number-one and number-two wheels to the right, one marker division at a time through 62, while placing the number-three wheel on 52 and returning to your contact point for a reading. From the graph we find that the exact low area of the number-one and number-two wheels is 64, and with number-three wheel on 52, we obtain the best indication or reading.

Isolating Individual Wheels

It can be seen from the first graph (number one) that when we were carrying all three wheels to the right and taking readings, that the position of the marker for number 52 read 11 7/8 on the dial. Now, on graph number two with the number-one and number-two wheels on 64 and number-three wheel on 52, our best reading was 11 1/2. So, how is it possible to determine which wheel is giving a good indication at 64, because it could be either the number-one or number-two wheel?

Isolating the Number-two wheel

- **Turn the dial right four times to 64. Turn the dial left for one complete revolution, picking up the number-three wheel at 64 and continuing left one more revolution to pick up the number-two wheel at 64 and stopping at 74;**

- **Turn the dial right one complete revolution, picking up the number-three wheel at 74 and stopping at 52;**

- **Turn left to the contact point, and take a reading. If a good indication has been lost, chances are that the number-two wheel, which is set on 64, was the one giving the good indication or reading. If a good indication remains, then the number-one wheel was providing the reading. In our case, the good indication was lost, thus demonstrating that 64 is the number-two wheel, or the second number of the combination.**

We have now derived what we believe to be two of the three numbers of the combination: those for the number-two wheel (at 64) and the number-three wheel (at 52). By the process of elimination we must now find the combination setting of wheel number-one.

- **Turn to the right four times stopping at 97 1/2;**
- **Turn to the left three times to 64;**
- **Turn to the right two times to 52, left to the drive cam opening, and oscillate the dial back and forth between contact points. Rapid oscillation after trying each combination setting will yield information from the sound and feel of the dial as the gate of the number one wheel is reached. If the true gate position is one or two divisions off from that shown on the graph, the fence can be worked into the gating by this method, thereby deriving the exact reading;**
- **Turn right four times stopping at 95.**
- **Turn left three times to 64. Turn right two times to 52.**
- **Turn left to the drive cam opening, and oscillate the dial back and forth between contact points. Continue moving the number-one wheel every 2 1/2 divisions, each time placing the number-two wheel on 64 and the number-three wheel on 52, until the lock is open. In most cases,the number-three wheel usually indicates first.**

Within the imperfect world of combination locks, **any** wheel can provide the initial indication. In the following example, the number-two wheel has been verified as giving the first positive reading. Now, the gate position of the number-three wheel should be determined, because it is usually the easiest to move.

Isolating the Number-Three Wheel

It is critical to correctly be able to isolate and identify each indicating wheel. Three examples are presented in the following pages to demonstrate the correct procedure. In these exercises, we wish to target wheel number-three.

Example 1

In our first example, we find that a good indication is at 36, which we have proven to be the number-two wheel. In the following exercise, the position of the number-one and number-two wheels will remain at 36, and they will not be disturbed.

- **Turn the dial right four times stopping at 36;**

- **Turn the dial to the left for one complete revolution, picking up the number-three wheel at 36 (leaving the number-one and number-two wheels at 36), and stop at 37 1/2;**

- **Turn the dial right to the contact point, take a reading, and record on the graph;**

- **Turn the dial to the left, picking up the number-three wheel at 37 1/2 and stopping at 40;**

- **Turn the dial right to the contact point, take a reading and record on the graph. Continue moving the number-three wheel every 2 1/2 numbers completely around the dial, each time taking a reading and recording it on the graph. Remember, as the number-three wheel is moved through the contact area, only a slight rotation of the dial will be required in order to take a reading;**

Example 2

Another example is provided, where the contact point is 3 1/4, with the number-one and number-two wheels on 36. The number-three wheel is moved left every 2 1/2 divisions past the contact point, stopping at 5.

- **Turn the dial to the right only 1 3/4 numbers to the contact point, which is at 3 1/4, and take a reading and record the information;**

- **Turn the dial to the left and at 5, pick up the number-three wheel and move it to 7 1/2;**

- **Turn the dial to the right only 4 1/4 numbers to the contact point, take a reading, and record the data. Continue moving the number-three wheel to 35;**

- **Check your graph for the lowest area and determine the exact low point of the number-three wheel by moving the number-three wheel over this area, one division at a time. What if you found the number-three wheel to be set on 82. You already**

have the combination setting of the number-two and number-three wheels. Follow the same procedure as before by moving the number-one wheel 2 1/2 divisions for each reading, and for each sample, set the number-two wheel on 36, and the number-three wheel on 82, until the lock is open.

Example 3

- **Turn right four times to 97 1/2;**
- **Turn left three times to 36;**
- **Turn right two times to 82;**
- **Turn left to the contact point or drive cam opening, and oscillate dial.**

Example 4: Number-One Wheel Indicates First

We will now explain what to do if the number-one wheel indicates first. In most cases when this occurs, the number-two wheel will indicate next.

In this example, you have determined the exact location of the low point for the number-one wheel from your graph, at 27. Proceed as follows to isolate the indicating wheel.

- **Turn the dial right four times, stopping at 27;**

- **Turn the dial to the left two complete revolutions, picking up the number-three wheel on the first revolution at 27, and the number-two wheel on the second revolution at 27, and moving them both to 30;**

- **Turn the dial to the right to the contact point, take a reading and graph the data;**

- **Turn the dial to the left, picking up the number-three and number-two wheels at 30, and stopping at 32 1/2;**

- **Turn the dial to the right to the contact point, take a reading and record the data;**

- **Continue moving the number-three and number-two wheels to the left every 2 1/2 divisions**

completely around the dial to 25, each time taking and recording the reading. These actions have been accomplished without moving the number-one wheel that we left set at 27;

- **Determine the exact low point of the number-two wheel (assuming it to be at 47), and use the process of elimination for the number-three wheel. This is quite simple, because the wheel is easily moved without disturbing the others;**
- **Turn the dial right four times to 27;**
- **Turn the dial left three times to 47;**
- **Turn the dial to the right one revolution, picking up the number-three wheel at 47 and stopping at 45;**
- **Turn the dial to the left to the contact point and oscillate back and forth over the drive cam opening;**
- **Turn the dial to the right, picking up the number-three wheel at 45, then move to 42 1/2;**
- **Turn the dial left to the contact point and oscillate back and forth over drive cam opening.**
- **Continue moving the number-three wheel to the right every 2 1/2 divisions until the lock is open.**

In this example, the number-three wheel has been moved around the dial without disturbing the position of the number-one or number-two wheels, which were left on 27 and 47 respectively.

CHAPTER THREE: Manipulation of Mechanisms other than the Lever Fence

Introduction

In the preceding chapter, detailed procedures and examples demonstrated the methods to manipulate the lever fence lock. In the materials that follow, information will be presented regarding the techniques that are employed for the rotary fence gear-driven, rotary fence spring-loaded, straight-in tail piece, bottom-drop, and off-set gear driven mechanisms. Although the fundamental principles are the same, the methods required in obtaining accurate readings or indications will differ.

Manipulation(539) Procedures for Rotary Fence Gear-driven Locks

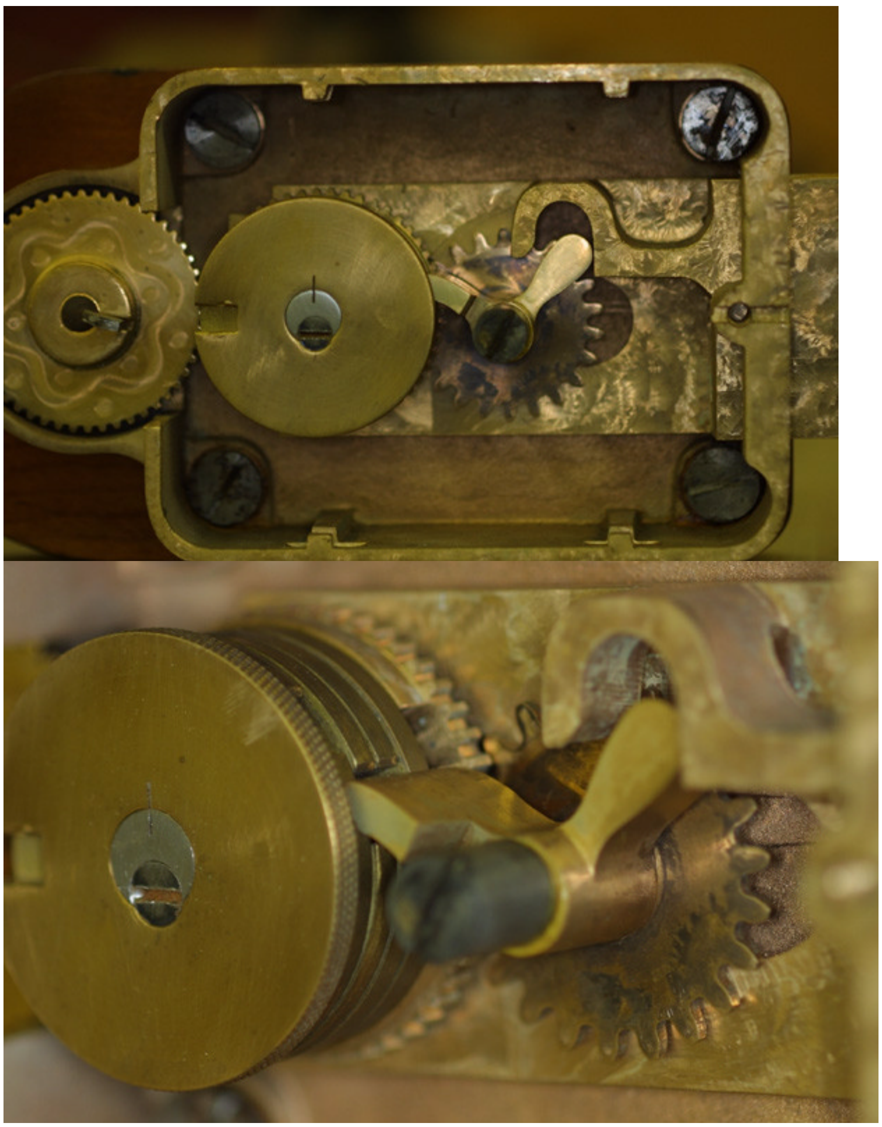

Figure M08. Rotary fence, gear driven lock.

It will be recalled that the lever fence mechanism offers two contact points that can provide data as to each wheel, although the sloping side of the fence offers more qualitative information. In the rotary fence gear-driven lock, readings can only be taken by rotating the dial counterclockwise. This is due to the mechanical design of the lock: as the dial is turned to the right, the friction between the gear and the fence moves the fence away from the drive cam and wheels.

If the dial is rotated to the left, however, the fence moves **toward** or against the drive cam and wheels, allowing the taking of readings at the drive cam opening.

Occasionally, due to variances in manufacturing, the drive cam is smaller than the wheels, thus allowing the fence to ride on the tumblers. By slowly and carefully turning the dial to the left, the gatings can sometimes be heard or felt as they rotate past the fence.

Manipulation Procedures for Spring-Loaded Rotary Fence

Figure M09. Yale OC9 spring roller fence lock.

This lock is manipulated in the same manner as the lever fence mechanism, described earlier.

Manipulation Procedure for Straight-in Tail Piece

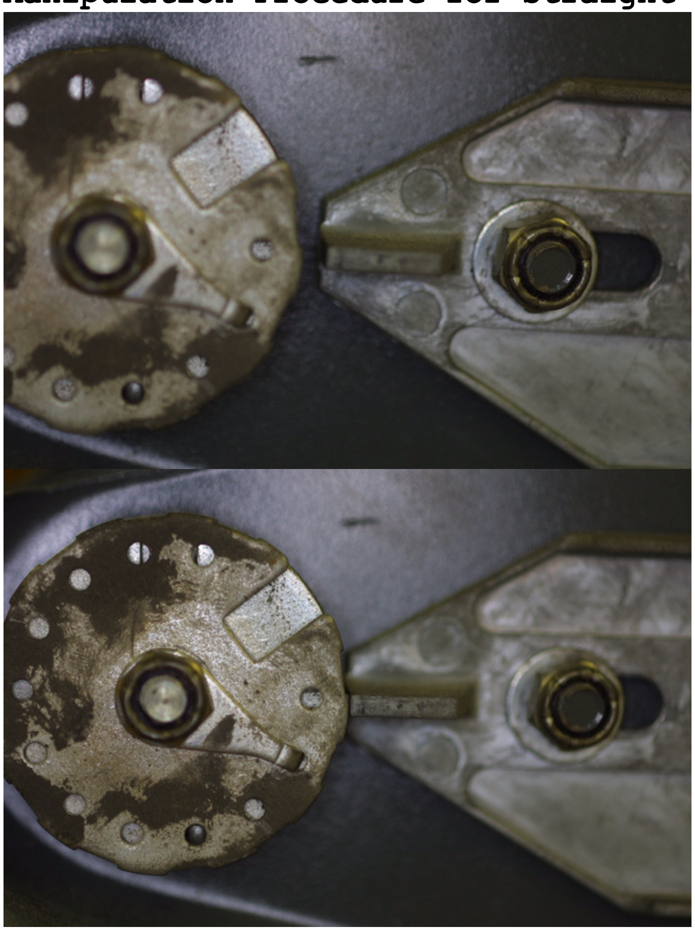

**Figure M10. Straight tail piece. Pressure can be applied directly against the wheel
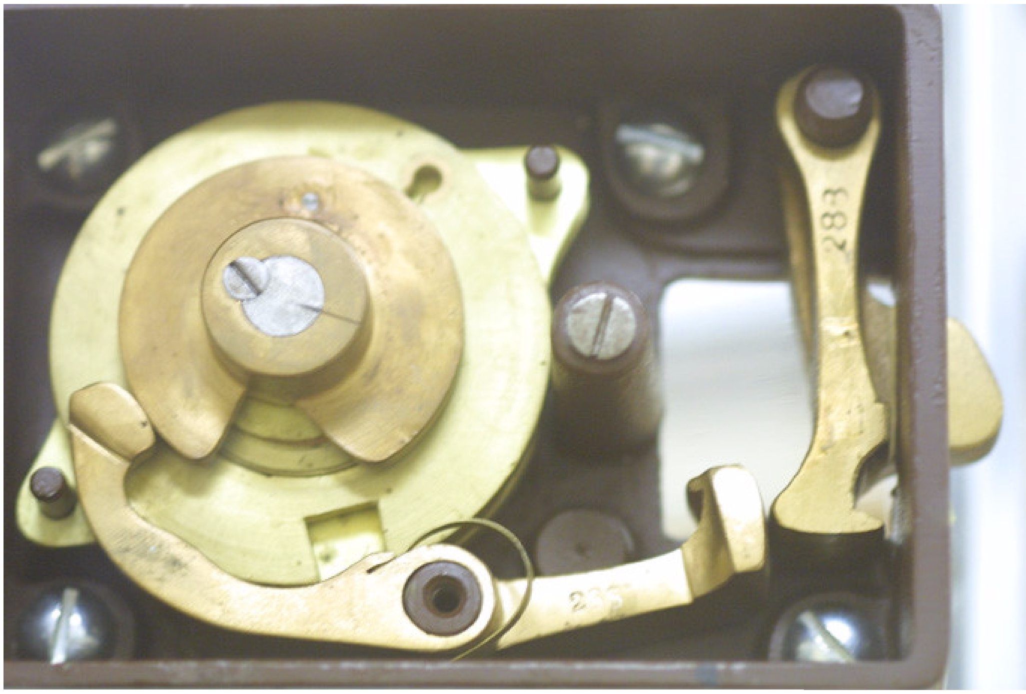
pack to determine gate position.**



The mechanical design of this lock differs from all other types, and requires that contact indications and readings must be taken and charted from the **handle**, rather than from the dial.

To provide contact indications, a pointer must be constructed of approximately twelve and eighteen inches in length, and affixed to the handle of the safe. Located at the tip of this pointer, a sheet of paper is taped to the door and marked with graduations of 1/16”, to simulate the dial divisions for position data.

Once the pointer is in place, determine the drive cam opening. Often, there are false gatings in several places around the drive cam, although the true gating is usually narrower. By rotating the dial with pressure on the handle, a determination can usually be made as to which is the true gating or drive cam opening by the amount of play in the dial, when held by the handle tail-piece.

Once the location of the drive cam opening has been ascertained, follow the same procedure as described for the lever fence lock, with the exception that readings are derived from the pointer attached to the handle.

Manipulation Procedure for Bottom-Drop Mechanism

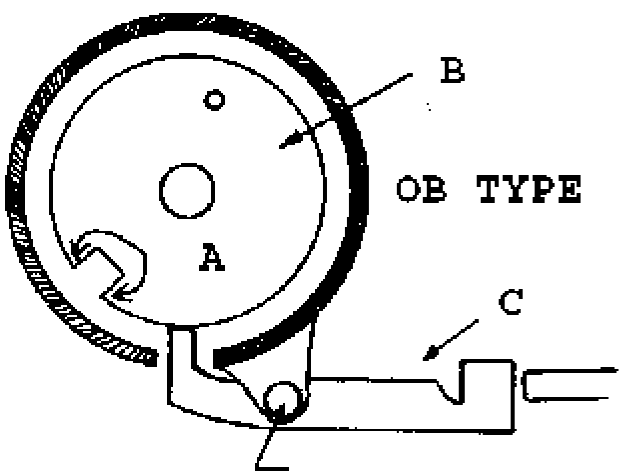


Figure M11. Bottom drop mechanism. In the diagram, (A) are the contact points, (B) is the drive wheel or cam,
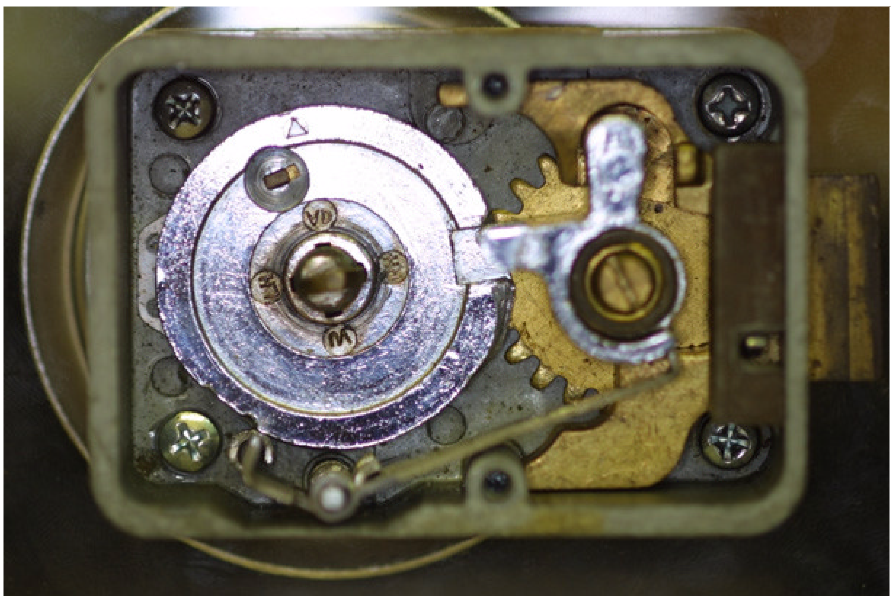
(C) is the lock dog or fence.

There are two different designs incorporated in this type of mechanism: **gravity fence**, and **handle pressure actuated fence.** These locks have two contact points; either will usually provide the same indications and readings.



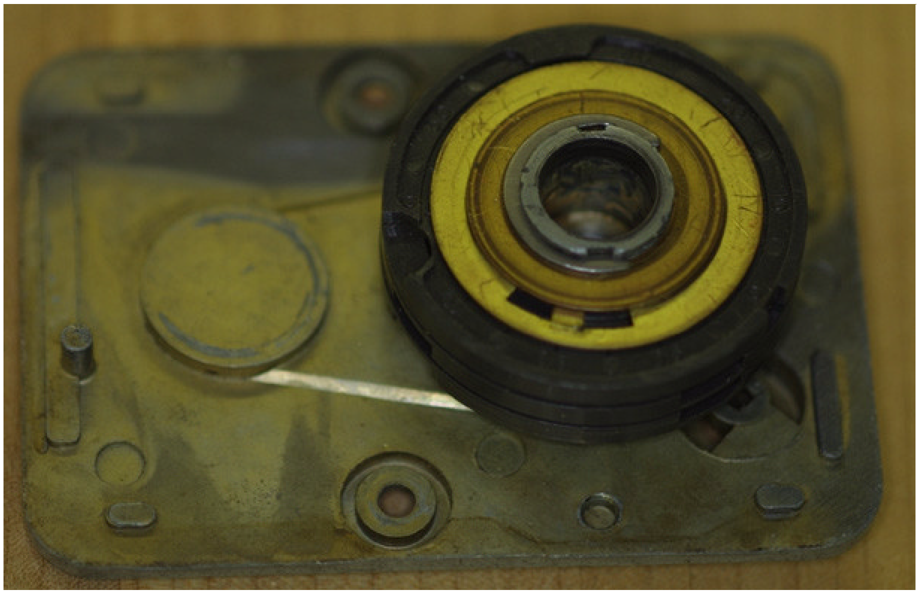
A. Gravity Fence

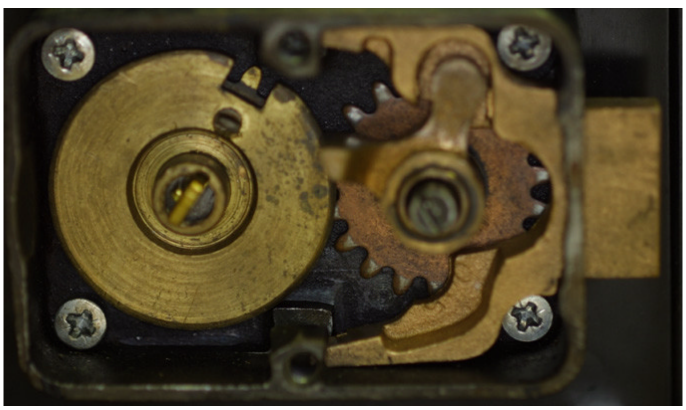
This lock is manipulated in the same manner as the lever Fence.

B. Fence Actuated by Handle Pressure

These devices are manipulated in the same manner as the lever fence, except that the handle must be turned to raise the fence so that it will contact the drive cam opening and wheels in order to take readings or indications.

Manipulation Procedures for Offset Gear-Driven Locks





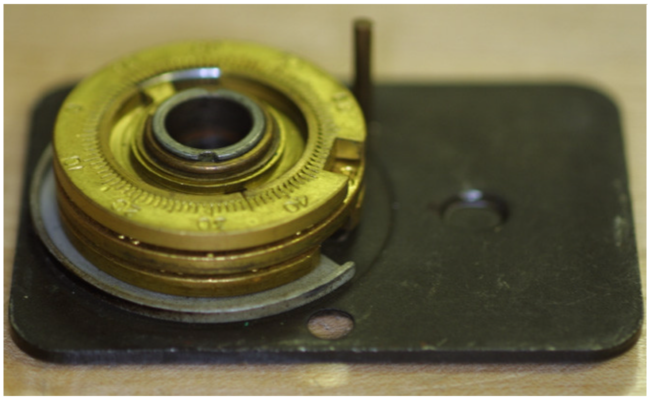


Figure M12. Yale B30 Manipulation resistant 1950 vintage UL 1R label.

Manipulation is accomplished in the same manner as with the direct drive locks described above; however, they are more difficult to read, due to the slack in the gears. The technique requires greater practice to become proficient.

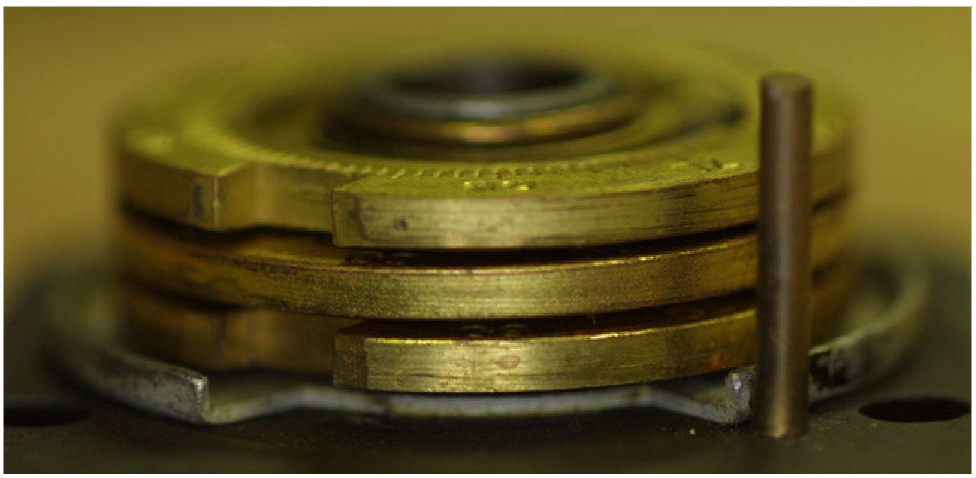

Figure M13. Yale OC5 geared roller fence. Only the left contact is read.

CHAPTER FOUR: Manipulation Resistant (MP) Locks

As with traditional key locks that boast that they are pick-proof, so also, there is a class of mechanical combination locks, designated as Group 1 devices, that are manipulation-resistant. Although most key and combination locks can be manipulated in one form of another: it is simply impractical with certain high-security and Group 1 designs. Since the original edition of this manual was written almost fifty years ago, the introduction of sophisticated microprocessors such as employed in the unique Mas-Hamilton X-07 and X-08, have created a class of locks that simply cannot be manipulated.

Mas-Hamilton has developed a highly sophisticated system called the Soft Drill, that actually performs manipulation on several popular combination locks, through the use of sound and mechanical feedback from the lock. The information from surface sensors is fed through a microprocessor and displayed on a laptop computer. The system will open many Group 2 locks. The reader is referred to **Chapter 36** for additional information.

Certain MP and MR Group 1 combination locks can theoretically be manipulated, and thus, information is presented here regarding the technique. The author utilizes the term "theoretically" to describe these manipulation processes because, although impractical, it is possible.

Rotary Fence Gear Driven MP Locks

This lock is almost identical to the older design, except for an additional lever that has been added to hold the fence away from the drive cam and tumblers until the proper combination has been run. It then drops into a narrow gating in all of the wheels, and allows the fence to contact the drive cam and open the lock.

This piece will be referred to as the manipulation-resistant lever. Instead of taking readings at the regular drive cam opening and fence, all of the indications will be derived from this lever, together with the small gatings in the tumblers and the slight depression in the drive cam into which this lever drops when the lock is opened.

The point of contact will be approximately 2 or 3 on the dial, where this manipulation-resistant lever contacts the edge of the depression on the drive cam, as the dial is rotated to the left. Although this lock has four tumblers, they often are only set on three numbers.

As an aid in obtaining readings or indications, it is usually necessary to mount a good magnifying glass or reading glass over the dial, in order to see the indications, as they are very slight. Also, a large pointer, twelve to eighteen inches long, may be attached to the dial, as in the case of the safe handle on the straight tail-piece.

This will increase the slight variations in indications to an extent that they will be more easily read. Otherwise, the lock is manipulated in the same manner as the regular rotary fence

gear driven device.

Lever Fence Mechanism

This lock is similar in outward appearance to the conventional version for the same manufacture. After dialing the combination setting, turn the dial to 100 and push in, allowing the lever to drop into the drive cam opening and rotate the dial to the right, retracting the bolt. The dial is spring loaded and can only be pushed in at 100.

In order to manipulate this lock, it is necessary to secure a machinist's dial indicator and mount it on the front of the safe, with the tip of the indicator touching the outermost point of the dial knob.

The manipulation procedure is the same as a regular lever fence lock, except that each time a reading is obtained the dial is set on 100, and pushed all the way in, allowing the lever and fence to drop down on the wheels. Then slowly let the dial come out until the lever contacts the beveled edge of the drive cam; take a reading on the dial indicator at this time. The lesser reading on the dial indicator will possibly be a combination setting. Although possible, this is a highly impractical procedure, due to the time required. It will be remembered that the applicable UL standards for manipulation-resistant locks require a minimum of 20 man-hours of manipulation resistance. See **Chapter 37**.

Conclusion

Manipulation requires a great deal of practice to become proficient. Attention to detail and perseverance, together with the technical understanding of the lock, and mechanical aptitude are prerequisite to mastering the Art of Manipulation.

11 (Popup - MULTIMEDIA LINKS)

 This icon appears before any audio or video link contained within this infobase, where the material is contained on the Infobase CD. It denotes the use of Windows Media Player, which can be downloaded from Microsoft. Most of the multimedia clips are contained on separate CD/ROMS, due to their size. They will be referenced by security level and disk number as well as the icon shown below. Please note that you may notice a synchronization error between audio and video on certain long sengments. This is usually due to buffering problems on your computer, or lack or resources, combined with the encoding process for streaming video.

This Icon denotes video links to other CDs in the LSS+1xx, LSS+2xx, LSSx3xx, or LSSx5xx series. Note the difference in background color. You must have these disks as well as the appropriate security clearance to view the material.

The following coding shall be utilized in all versions of **LSS+** and **LSS+/x** to indicate the infobase to be opened:

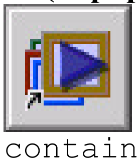
LSS-**1xx**   **Public access level, no restrictions on access**
LSS-**2xx**   **Restricted distribution to locksmiths and safe technicians**
LSSx-**3xx** **Restricted to government agencies only, and certified safe technicians**
LSSx-5xx Restricted to government agencies only. This material deals specifically with SWAT team operations and the use of explosives for breaching.

Security level is shown in red; disk series is shown in green. The combined identifier is the name of the Infobase where the multimedia clip is contained.

The designation following the security level denotes the disk number, beginning with 01, and will be issued in sequential order, as material is added to the Infobase.

NOTE: You will be required to open the infobase on the designated disk, and link to the file in order to view or listen to the clip.

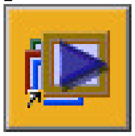
There are hyperlinks contained within this CD/ROM to www.security.org, and many other websites. You must be on-line for these links to function properly. Please contact the site administrator at security.org to advise of any problems or invalid links.



A master index of multimedia content can be found at the beginning of each chapter, and in the Master Exhibit listing at the beginning of the book.

Note that in certain cases that there are links within the Master Exhibit listing to both images and multimedia. The icon always is utilized to link to
audio and video files; the text (in green) links to images, if available.

NOTE REGARDING MULTIMEDIA LINKS: These Infobases are extremely large (in excess of 600 MB) and therefore require a great deal of RAM to run properly. If your computer has less than 256 MB. of RAM, you will find that the system will take a long time to load linked materials on LSS Infobases. You may go directly to the indicated disk and launch the multimedia material directly, rather than waiting for the system to locate and load the file.



SPECIAL NOTE REGARDING ISP EXHIBITS: There are special identification numbers for all exhibits from the Illinois State Police. These are identified as ISP-12-3456, where ISP = Illinois State Police, 12 = the photograph ID as it appears on the original Kodak PhotoCD translation, and 3456 is the CD reference number for internal use. Many of the audio clips associated with the ISP exhibits refer to the reference numbers denoted in the captions. Appreciation is expressed to Bill Sherlock, retired Chicago Police Department Forensics Examiner. He is currently assigned to the Illinois State Police Forensics Laboratory in Chicago. Bill Sherlock and Art Paholke worked together for many years, and were the pioneers in the development of forensic analysis of locks.

12 (Popup - MULTIMEDIA LINKS)

This icon appears before any audio or video link contained within this infobase, where the material is contained on the Infobase CD. 13 (Popup - OVERVIEW OF LOCKS, SAFES, AND SECURITY)

The Electronic Infobase of ***Locks, Safes, and Security*** (Second Edition) combines the data within the hardbound edition and extensive multimedia and supplementary references. The first edition of Locks, Safes, and Security was published in 1970, and achieved recognition within the law enforcement community for its detail and thorough coverage of topics relevant to law

enforcement. Thirty years later, the second edition was released, in December 2000. The text is extremely comprehensive, and provides the reader with an understanding of the subject matter relating to locks, safes, and security. The book was specifically written for law enforcement investigators, criminalists, and intelligence agencies. Its secondary audience is the professional locksmith and safe technician.

14 (Popup - THE ART OF MANIPULATOIN)

This manual was originally published in 1955, and was the first real description of the manipulation process. The author has rewritten the text and added photographs for clarity. Although the work was relatively short in length, thousands of copies have been sold to locksmiths throughout the world.

15 (Popup - A TREATISE ON FIRE & THIEF-PROOF DEPOSITORIES AND LOCKS AND KEYS)

PREFACE to the SECOND EDITION

George Price wrote an extremely comprehensive work on the history and development of locks and safes during the time of the Great Exhibition in London. This was a period of significant advancements in the design of locks, safes, and vaults. His treatise provides a rich insight into the state of security technology of his day. When I was first introduced to this work by Horace Smith in England, I was fascinated by the chronicle of historical development of the forerunners to modern locking systems.

It was immediately obvious that this work should be updated and integrated into the Electronic edition of ***Locks, Safes and Security***. Although I have taken license to change some of the traditional English verbiage in order to enhance readability in our modern world, I have also attempted to insure that the excitement, intrigue, and ingenuity of the era and its pioneers remains intact.

The Electronic Infobase Edition of ***Locks, Safes, and Security*** allows the flexibility to link and combine the information within these two books with a third by Alfred C. Hobbs. I hope that this allows the reader to gain a deeper understanding of how locks and safes were developed, and the difficulties that were encountered by the craftsmen in Wolverhampton, Willenhall, and throughout Europe and America. Links to other areas of the Infobase are designated by **[**brackets**]**.

One of the video segments that can be found within this infobase was shot in London with Jeremy Bramah, a distant relative of Joseph Bramah. I believe that the reader will find that this provides more insight into the era of the Great Exhibition and complements the work of George Price.

Mr. Price provided a timeless and valuable chronicle of events that ultimately resulted in the security principles and devices of the twentieth century. I hope that the availability of his work furthers an understanding of the locksmith profession, and an appreciation of the difficulties in bridging the forty centuries from the first Egyptian lock, to the modern highly technical world of security and its practitioners.

16 (Popup - LOCKS AND SAFES: THE CONSTRUCTION OF LOCKS)
The author has rewritten the original edition of LOCKS AND SAFES: THE CONSTRUCTION OF LOCKS, and released it as a second edition. A. C. Hobbs was both a lawyer and locksmith. He is credited with the bypass of the Bramah lock at the Great Exposition in London in 1851, thereby causing a cascade of inventions and improvements in locks, safes, and security hardware. His book provides a different perspective from that of the Price book, also contained within this Infobase. All of the original graphics have been reproduced.

MWT

PREFACE

THE reader is entitled to know the origin of the small work which he holds in his hands.

In August 1852, being about to write a short article on Locks for a Cyclopedia of Useful Arts, of which I am the editor, I consulted my esteemed and lamented friend, the late Professor Cowper, of King's College, as to the desirability of explaining to the general reader the defects of some of our English locks, which, previous to the celebrated "lock controversy" of 1851, had borne a high character for skilful construction, beauty of workmanship, and undoubted security.

Professor Cowper expressed his strong conviction that by exposing the effects of our locks, the cause of mechanical science, as well as the public in general, would be benefited; that if our locks were defective, inventors would be stimulated to supply the

defects, and the art of the locksmith would be raised accordingly.

He considered that Mr. Hobbs had made a considerable step in advance in the constructive details of his art, not only in having detected the weak points of some of our best English locks, but also in having introduced two or three new locks, which appeared to be more secure than any of those previously produced.

Professor Cowper gave me an introduction to Mr. Hobbs, who placed at my disposal a variety of literary materials relating to the history and construction of locks, and stated his intention at some future time of bringing out a small book on the subject, if he could meet with a publisher. I recommended him to offer the work to Mr. Weale, for insertion in his series of Rudimentary Works. This was accordingly done, and I was invited to prepare the work; but as my engagements did not leave me sufficient leisure to write the book, I requested my friend Mr. George Dodd to put the materials together, and to search for more.

Mr. Dodd acceded to my request; and having completed his part of the work, I subjected it to a careful revision, and added various details which seemed to be necessary to completeness, at least so far as the narrow limits of a small rudimentary work would admit of completeness. The manuscript was then sent to press.

Each sheet as it was received from the printer was submitted to Mr. Hobbs, who read it with care, and made his annotations and corrections thereon. Mr. Hobbs and I then had a meeting, when the additions and corrections were read and discussed, and admitted or rejected as the case might be. The sheet having been thus corrected was sent to press.

It should also be stated that, during the progress of the work, Mr. Weale, at my request, wrote to Messrs. Bramah, and also to Messrs. Chubb, informing them that a Rudimentary Treatise on the Construction of Locks was being prepared, and requesting them to state in writing what alterations or improvements they had made in their locks since the date of the Great Exhibition. The communications which we have received from these celebrated firms are inserted verbatim, in their proper places, in the present work.

Such is the mode in which this small volume has been prepared. I have endeavored to perform an editor's duty conscientiously,

without entertaining the feeling of a partisan in the matter. My chief object in superintending the production of this book (an object in which the Publisher fully participates) is to advance the cause of mechanical science, and to supply a deficiency in one of the most interesting portions of its English literature.

C. TOMLINSON.
July 1853.

17 (Popup - REVISIONS FOR LSS+)
The following material applies to all release versions of **LSS+.** Changes, deletions, and additions are referenced by the release version number contained on the **CD/ROM.**

The **LSS+ CD/ROM** has been greatly expanded and updated since the printing of the second edition of ***Locks, Safes, and Security*** in December, 2000. The Electronic Infobase edition contains material which could not be included within the hardbound edition, due to space limitations. A master listing of all additions to the electronic edition is contained within this pop-up screen.

The additions to the second edition of the text include color graphics, additional photographs to more thoroughly describe the topic, exploded views within photographs, and audio and video clips to enhance understanding by the reader.

Full-text patents, as well as links to materials contained within the Infobase at **www.security.org**, are accessible within this CD/ROM.

You will note that figures that have been added to the electronic Infobase edition are labeled with a separate **LSS+** number, to distinguish them from illustrations within the hardbound edition. All of the figures contained within this CD/ROM are indexed in a Master Exhibit Listing at the beginning of the text, as well as at the beginning of each chapter.

You can search for any chapter and section heading by entering the chapter_section number, separated by an underscore, within the query dialog box.

MASTER UPDATE SUMMARY FOR LSS+ Version 4.05.

Chapter One

Add text to section 1_3.0

Illustrations added.

Figure LSS+102 Examples of pin tumbler locks from different cultures.
Figure LSS+103 A Pin tumbler lock found in Northern Africa.
Figure LSS+104 A 17th Century Persian padlock.
Figure LSS+105 An early Roman padlock.
Figure LSS+106 An early European padlock.
Figure LSS+107 An early warded lock.
Figure LSS+108 An early warded lock mechanism.
Figure LSS+109 A warded lock produced between the 15th and 18th century.
Figure LSS+110 An example of a Roman lock.
Figure LSS+111 A warded door lock.
Figure LSS+112 An example of a Barron lock
Figure LSS+113 An analysis of the movement of the bolt within the Barron lock.
Figure LSS+114 The Appointment by the Queen of the Bramah Lock Company.
Figure LSS+115 The Pillard time lock.
Figure LSS+116 Hobbs and Hart lever lock
Figure LSS+117 Map of England
Figure LSS+118 The Bramah lock that was successfully opened by Alfred Hobbs.
Figure LSS+119 Bramah lock, view of sliders.

Locksmith training in Denmark, in comparison to the United States. Courtesy of Hans Mejlshede.

Chapter Three

Illustrations and new definitions added.

Figure LSS+301 Axial pin tumbler lock
Figure LSS+302 Arc ring
Figure LSS+303 Auxiliary deadlock latch bolt
Figure LSS+304 Blade of key
Figure LSS+305 Blank key
Figure LSS+306 Cam and cam lock
Figure LSS+307 Case ward
Figure LSS+308 Change key for combination lock

Figure LSS+309 Code cut original key, direct reading code
Figure LSS+310 Connecting bar
Figure LSS+311 Corrugated key for warded padlock
Figure LSS+312 Cut root for pin tumbler key
Figure LSS+313 Deadbolt
Figure LSS+314 Dimple key for Sargent Keso lock

Chapter Four

Illustrations added, and the following sections:

Add Section 4_2.4 Automobile Entry Tools
Add Section 4_2.5 bypass Tools
Add Section 4_2.6 Bypass tools for Safes and Vaults
Add Section 4_4.2.7 Forensic Investigative Tool Set
Figure LSS+401 Single and double cut files.
Figure LSS+402 Two file sets produced by HPC.

Macro lens, Courtesy of Hans Mejlshede.

Data back for documentation of images. Courtesy of Hans Mejlshede.

Photographic equipment requirements. Courtesy of Hans Mejlshede.

Ring strobe is a necessity for forensic photography. Courtesy of Hans Mejlshede.

Forensic marks and their observation with proper lighting. Courtesy of Don Shiles.

Chapter Five

Illustrations and definitions added.
Figure LSS+501, Periodic table.

Chapter Six

Figure LSS+601 Back-cut key
Figure LSS+602 Laser track keys from Volvo and Mercedes
Figure LSS+603, Pin tumbler key, showing steeples
Figure LSS+604, Keyway wards
Figure LSS+605, John Falle comb pick
Figure LSS+606, Ikon paracentric keyway
Figure LSS+607, Key head identifying markings (Sargent)
Figure LSS+608, Key head identifying markings (Ilco and Silca)
Figure LSS+609, Milled key blank

Chapter Seven

Figure LSS+701a Design of a key
Figure LSS+701b Key component design
Figure LSS+701c Code cut key, showing symmetry of design
Figure LSS+702a Improper alignment between cuts of a key and pin chambers
Figure LSS+702b Correct registration of key between cuts and pin chambers
Figure LSS+703 Bow of key
Figure LSS+704 Shoulder of key
Figure LSS+705 Depth and spacing diagram
Figure LSS+706 Depth and spacing of keys
Figure LSS+707 These diagrams show an example of different pin lengths utilized by Schlage.

Conversation with Chuck Murray, Kaba-Ilco, regarding keys and their production.

Chapter Eight

Illustrations and supplementary materials added to sections on clay and silicone casting.
Add Section 8_7.1.4.1 Add Impressioning of stamped numbers on metal
Figure LSS+801 An HPC SKM-2D key micrometer for direct reading of bitting depths
Figure LSS+802 An HPC HKD-75 key gauge for reading bitting depths
Figure LSS+803 An HPC axial lock depth gauge TKPD-1
Figure LSS+804 A factory original key with a direct code that correlates with bitting depths for each cut
Figure LSS+805 The mold is prepared for clay impression of a key
Figure LSS+806 Talc or other lubricant is applied to allow release of the source key from the clay
Figure LSS+807 Excess clay is trimmed from the edge of the mold
Figure LSS+808 The source key is positioned within the mold
Figure LSS+809 The key is impressed into the clay mold
Figure LSS+810 The mold is closed with the key inserted to create an impression
Figure LSS+811 The mold is opened after an impression is taken
Figure LSS+812 Source key is removed from the mold
Figure LSS+813 A channel is made in the clay for the escape of gasses created during impressioning
Figure LSS+814 The mold is secured in a locked position
Figure LSS+815 Low temperature metal is heated and poured into the mold
Figure LSS+816 The mold is allowed to cool and opened

Figure LSS+817 The target key is removed from the mold
Figure LSS+818 Silicon is poured into a container to make an impression of a source key
Figure LSS+819 The silicone is cut in half to show the details of an impression
Figure LSS+820 A source and target key produced by silicone impressioning
Figure LSS+821 HPC 747xu tubular key duplicator
Figure LSS+822 HPC 1200 key duplicator
Figure LSS+823 HPC handheld key code computer (HP720)
Figure LSS+824 HPC KM-60 micrometer

Figure LSS+3508. Punching involves the wheel pack being forced inward

Figure LSS+3509, diagram showing how a safe is peeled by gaining an access point to remove layers of metal.

Figure LSS+3510. In this figure, peeling was accomplished from the corner using a cold chisel.

Figure LSS+3511 This was a peel and punch attack to access the bolts (left). A classic peel attack is shown (right)

Figure LSS+3512, examples of peeling of the outer skin on the top of the container and the rivets popped.

Figure LSS+3513 Prying and wedging.

Figure LSS+3514 A safe that has had the door pulled loose by the application of extreme pressure.

Figure LSS+3515, (ISP 38-3563 left, and 39-3563 right). The result of pounding of components.

Figure LSS+3516, Bolts were sheared from shock waves through the use of the welded bar to the front of the door.

Figure LSS+3517. Example of punching. Pressure was applied to the hinge side.

Figure LSS+3518. This was a pound attack. The door was pounded with many hits.

Figure LSS+3519, An attack by the use of a wedge to pry apart and separate portions of the container.

Figure LSS+3520, The top of the safe was cut into to provide access to the bolt works.

Figure LSS+3521 Attacks by torch. In the middle picture, an inept attempt to open the safe by cutting through the side.

Figure LSS+3522. Attack using a torch where there was obviously no knowledge of where to cut.

Figure LSS+3523 Additional examples of the use of a torch. In the photographs, the lock box is burned out.

Figure LSS+3524 Lines scored by an oxy-acetylene torch in the outer shell of a Chubb safe.

Figure LSS+3525, examples of torch attack. Incorrect tools were utilized on the side of the safe.

Figure LSS+3526, attack by torch that did not result in an opening.

Figure LSS+3527, A torch attack where burglars cut a portion from the door for access.

Figure LSS+3528, Examples of attack by oxyacetylene.

Figure LSS+3529. The thermic lance develops high temperature and can be utilized virtually anywhere.

Figure LSS+3530 An example of a safe attacked with a thermic lance.

Figure LSS+3531 An example of arc welding with cutting rods.

Figure LSS+3532, A free-standing Chubb safe was attacked with explosives.

Figure LSS+3533 A safe was open with explosives, after being filled with water.

Figure LSS+3534 A fixed drill rig.

Figure LSS+3535 A burglary where it is suspected that a drill rig caused the fracture of the outer skin of the door.

Figure LSS+3536 Core drill can produce a large hole for

access to the bolt works or lock box.

Figure LSS+3537 Critical drill points are shown. This is a rear view, with the lock case removed.

Figure LSS+3538 (ISP 23-2963) Deflector plates made of angle iron are added to deter drilling.

Figure LSS+3539 (ISP 104-3563) The bolt is punched out of the way in order for the handle cam to be rotated.

Figure LSS+3540 Burglars drilled into the side of the safe to punch and drive the bolt out of the way.

Figure LSS+3541 A scope is inserted to obtain a view of the wheel pack.

Figure LSS+3542 The fence is a prime target for drilling, either the soldered link or the actual fence material.

Figure LSS+3543 Progression of movement of the fence into the gate of the wheel pack.

Figure LSS+3544 A 90 degree angle view with a borescope using a mirror on a Mosler MR 302.

Figure LSS+3545 Locating the fence for drilling.

Figure LSS+3546 A lever fence that has been drilled, and then removed.

Figure LSS+3547 Drilled relockers and zoom view.

Figure LSS+3548 Mosler MR-302 point of penetration.

Figure LSS+3549 Hole drilled through cover plate.

Figure LSS+3550 Side drilling and scoping the lock case.

Figure LSS+3551 Floor safe that has been angle drilled to view wheel pack.

Figure LSS+3552 Safe drilled from the top of safe to lock box to view the wheel pack.

Figure LSS+3553 Many burglaries are simulated.

Figure LSS+3554 The burglar uses a drill without much knowledge of the safe.

18 (Popup - REVISIONS FOR LSS+)
The following material applies to all release versions of **LSS+.** Changes, deletions, and additions are referenced by the release version number contained on the **CD/ROM.**

The **LSS+ CD/ROM** has been greatly expanded and updated since the printing of the second edition of ***Locks, Safes, and Security*** in December, 2000. The Electronic Infobase edition contains material which could not be included within the hardbound edition, due to space limitations. A master listing of all additions to the electronic edition is contained within this pop-up screen.

The additions to the second edition of the text include color graphics, additional photographs to more thoroughly describe the topic, exploded views within photographs, and audio and video clips to enhance understanding by the reader.

Full-text patents, as well as links to materials contained within the Infobase at **www.security.org**, are accessible within this CD/ROM.

You will note that figures that have been added to the electronic Infobase edition are labeled with a separate **LSS+** number, to distinguish them from illustrations within the hardbound edition. All of the figures contained within this CD/ROM are indexed in a Master Exhibit Listing at the beginning of the text, as well as at the beginning of each chapter.

You can search for any chapter and section heading by entering the chapter_section number, separated by an underscore, within the query dialog box.

MASTER UPDATE SUMMARY FOR LSS+ Version 4.05.

19 (Popup - REQUIRED SOFTWARE AND HARDWARE)

The size of the LSS Infobase is in excess of 600 MB. The LSS multimedia linked Infobases are about the same size. The combined size of the Infobase is greater than 4GB. Therefore, your system needs sufficient RAM and hard drive space to load these files.

In order to properly run LSS+, you must have the following

software and hardware configuration:

Windows 98 or later operating system
Display set at 1024 x 768 set to millions of colors
MAC OS 9 or X
Microsoft Word
Windows Media player version 7 or above
Intel Pentium III preferred
RAM: minimum 256 MB for proper operation
CD ROM or DVD drive, 4X read minimum
Internet connection to support embedded links within the text

If your display size is not set properly, the layout of each page will be incorrect, with regard to text and images. In older computers where the best resolution is 800 x 600 or 640 x 480, this can cause viewing problems.

NOTE: There is a DVD version of the Infobase available on one disk, for those that have the required hardware. Please contact the author for details.

20 (Popup - LINKS TO SECURITY.ORG)

www.security.org is the Internet supplement to **Locks, Safes, and Security** (Second Edition). The site contains an extremely comprehensive database about locks and safes. Detailed information regarding bypass tools and techniques is accessible, together with patent data, manufacturer listing, and comprehensive drill-point diagrams for all of the major safe and lock manufacturers throughout the world.

Much of the information contained within the website requires a security clearance for access, due to the sensitive nature of the information. You can obtain a clearance by **registering** on line.

21 (Popup - LINKS TO OTHER INTERNET SITES)

Links to many forensic sites, as well as leading lock and safe manufacturers may be found at **www.security.org**.

22 (Popup - LSS+/x CD/ROM)

The **LSS+ GOVERNMENT version CD/ROM** will contain restricted information regarding the bypass of locks and safes. Extensive video presents detailed instructions and discussion regarding the techniques and tools that can be utilized to open many high security locks. Bypass tools produced by John Falle, Mark Bates, Martin Newton, HPC, and other vendors are described.

In order to purchase a copy of this CD/ROM, you must be employed by a government agency responsible for covert entry. Certain restrictions apply to the purchase and use of this material.

NOTE: The Infobase for **LSS+** and **LSS+/x** is the same. The supplemental CD ROMs are supplied for each security level. Thus, only **LSS300** series disks will be provided for **LSS+ version/x**.

23 (Popup - ERRORS AND READER SUGGESTIONS)

This electronic edition is approximately 5GB in size. Inevitably, there will be errors that can only be found by the reader. The author would ask that errors in text, image display difficulties, missing hyperlinks to photographs or web sites, changed web links, content errors, and any suggestions should be e-mailed directly to the author at mwtobias@security.org. Likewise, if you would like to see specific materials included within later editions of this Infobase, please contact the author.

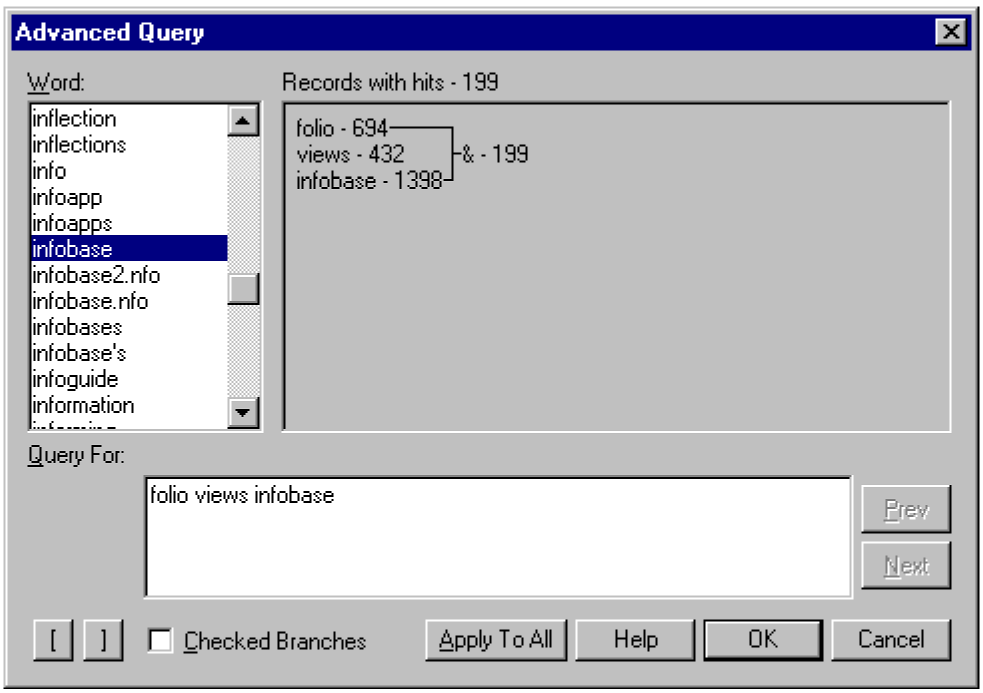
24 (Popup - ORGANIZATION OF THE INFOBASE)

The Electronic Infobase edition of ***Locks, Safes, and Security*** contains four separate books. Each appear at a separate location within the Infobase, but all are hyperlinked by topic, where appropriate. The index for ***Locks, Safes, and Security*** is also reproduced to enable the reader to more effectively search for specific topics.

All major headings within ***Locks, Safes, and Security*** are numbered to facilitate understanding and flow of material. You may search for a specific chapter and section by entering the chapter number and paragraph number, separated by the underscore character. Thus, searching for section 4.1.2 in chaptger 13 would be entered as 13_4.1.2.

All exhibits contain a specific Figure number. Within ***Locks, Safes, and Security***, these are identified by chapter and sequential number. For example, the third illustration is Chapter 14 would be identified as Figure 14-03. If there is more than one segment to an exhibit, then letters will designate the segments. Thus, if Figure 14-03 actually contained three parts, they would be identified as 14-03a, 14-03b, and 14-03c.

The numbering for exhibits that only appear in the **LSS+ CD/ROM** are distinctly identified with the chapter and individual number. Thus, the first exhibit in Chapter One to be added to LSS+ (but not appearing within the hardbound edition) would be labelled as LSS+101. This system applies to all multimedia, if identified separately.



All **patents** appear as a series of integers without any comma separation. To search for a specific patent, enter the number

without commas: patent 5,123,456 would be entered as 5123456.

25 (Popup - HELP FILES AND SEARCHING THE INFOBASE)

A detailed help tutorial is included with this program. To obtain help, enter [F1] function key. You may enter [F2] to search for a specific word, term, or phrase. The advanced search query template is shown below. This is accessed by entering [F2]. You will note that as each letter of a query term is entered, the system will search for all matches. If two or more terms are entered, then a search tree is displayed, showing the coincidence of hits for each term.

A custom query template is available by entering ctrl-F2. On-line help files may be found at **security.org/lss-tour**.

26 (Popup - NAVIGATION AND SEARCH TOOLS)

Color coding of Links

All hyper links within the infobase are color coded, as follows:

GREEN: hyperlink within infobase to another location

PURPLE: Program link. This opens another program to read the data within the link. For example, a document file will open Microsoft Word, then display the linked information.

LSS+ Electronic Infobase Edition Version 5.0

DARK BLUE: This is an OBJECT LINK to an image that appears full screen. Large photographs and patents utilize object links.

LIGHT BLUE: Internet links directly to the Web.

YELLOW: Pop-up notes, such as the one you are reading. A Yellow note icon can also indicate a pop-up link.

Searching for Section Headings

To go directly to a particular section, enter the chapter_section. Thus, to go directly to the beginning of chapter 31, enter **31_1.1**.

Searching for Patents

To search for a patent, enter the full number with NO commas. Thus, for patent 4,123,456, you must enter 4123456 in the dialog box.

Shortcut Search Commands

F1 Help Files. You may then search the HELP INFOBASE for assistance.
F2 Search

27 (Popup - USING THE ELECTRONIC INFOBASE)

This Infobase provides a sophisticated search engine to rapidly access information contained within the four books contained therein. Unlike the hardbound editions, any term or group of terms may be searched. Although some literature and manuals within the locksmithing trade have been converted to electronic format, none of them provide for the complex search tools that is available in **LSS+**. Typically, such files are converted to Adobe PDF (Portable Document Format). Although PDF files are convenient, they do not provide for rapid and complete searching.

This software allows for instant retrieval of any and all information contained within the Infobase. Every relevant word is indexed and a "hit list" is displayed as an item is entered. All hits are then highlighted within the text. You may simply press enter to continue advancing to each hit. Function keys may this process easy. A description of help functions is available under "help files," above.

The unique functionality of this Infobase will become apparent as you utilize the system. The integration of audio, video, graphics

and text allows the hardbound editions to be utilized as a platform for greatly enhanced access to data.

Depending upon access rights, you are allowed to highlight entries and print the material. You may also utilize the "shadow files" function to enter your own comments or notes at any point in the Infobase, for later reference. And, don't forget, all comments are also indexed.

You may also customize the appearance of the Infobase to suit your individual requirements.

Finally, you will note that there are several views displayed at the bottom of the page. By pressing the appropriate button (All, Search, Browse, Document, Contents, HitList, and Object). Each of these provides a different level of display, that is explained in the help files.

Understanding the Default Views

A ***view*** is a way of looking at information. Depending on what you are doing in an infobase, you may need to look at the information in different ways. To facilitate this, Folio Views™ provides seven different views of an infobase.

Each view contains one or more panes. Each pane presents a type of infobase data. The ***Document*** pane displays the body of the infobase — the text, objects, links, highlighters, and other data stored in an infobase. The ***Contents*** pane displays a dynamic table of contents for the infobase. The ***Hit List*** pane displays search results after a query is performed. The ***Reference Window*** pane is always connected to the top of the Document pane — it displays the path to the current information (such as Volume 1-Biology, Chapter 12, The Life Cycle of Amphibians).

The default views are all listed on tabs at the bottom of the infobase window. To change the view of an infobase, click on a tab.

The seven views are:

All — Displays the Contents, Document, Reference Window, and Hit List panes. Use this view when searching the infobase or when you need to see all of the related information at once.

Search — Displays the Document, Reference Window, and Hit List panes. Use this view when you are searching to find the most relevant information. (The Hit List can help you identify the most relevant sections in the infobase to begin reading once your search is completed.)

Browse — Displays the Contents, Document, and Reference Window panes. Use this view when you are browsing the infobase for information: it gives you the best access to the table of contents while maximizing the space allocated for the infobase text.

Document — Displays Document and Reference Window panes. Use this view when you need as much of the body of the infobase on the screen as possible.

Contents — Displays only the Contents pane. Use this view when you are navigating or scanning the table of contents and need to see the full name of the headings in the table of contents. (Double-clicking on a heading in the Contents view takes you to the appropriate section in the Document view.)

Hit List — Displays only the Hit List pane. Use this view after performing a search to view as many references in the hit list as possible. (Double-clicking on a reference in the Hit List takes you to the appropriate section in the Document view.)

Object — Displays only the Object pane. The Object pane is activated whenever an object link is followed.

28 (Popup - MASTER EXHIBIT LISTING)

There is a **master exhibit summary** at the beginning of this text, as well as within each chapter. You may hyperlink to an exhibit directly from this listing.

Note that all new exhibits for the electronic edition are identified by "Figure LSS+" numbering to differentiate from the printed edition.

29 (Popup - PHOTOGRAPHS AND MAPPING)

There are three levels of photographs contained within the Infobase. The original exhibits that are contained within the printed edition of **Locks, Safes, and Security** appear as in the original text. Their captions are contained within pop-up notes, denoted by a yellow folder. The captions contain the original numbering associated with each chapter and sequential exhibit. All of these photographs are reproduced in black and white.

Additions to the Electronic Edition are in color and carry their own caption and distinct numbering system, in order to differentiate from the original illustrations. Note that the numbering may be out of sequence because of the way the Infobase has been edited.

Many of the complex or multisegment photographs are "mapped" for hypergraphic links. If the cursor is moved over a picture, especially one that contains one or more sub-parts, links may be indicated by the arrow changing to a hand. In such case, left-click to link to a more detailed photograph. In most cases, hypergraphic links are utilized to allow for the display of a larger image.

Hypergraphic links may also appear as highlighted text, usually in **dark blue**. Simply click on the text to view the associated photograph.

Where there is significant detail contained in a photograph, the resolution has been set so as to allow for use of the zoom function to magnify the image.

30 (Popup - HELP USING INFOBASE SOFTWARE)

On-line help files are available at security.org.

You may find detailed help files for using Open Market software by entering **F1** from anywhere within the Infobase. The Open Market Folio Views[tm] program is recognized as the most sophisticated search engine of its kind. It allow you to format searches utilizing complex limiting criteria.

All of the information contained within this work have been assigned to information groups to assist in performing precise queries. You will note that there are many preformatted search templates to assist you in locating the information you require.

31 (Popup - SEARCH TOOLS AND QUERY TEMPLATES)

There are many ways to search for information within this Infobase. A summary of search tools is provided below. You may also obtain detailed help by pressing [Function 1].

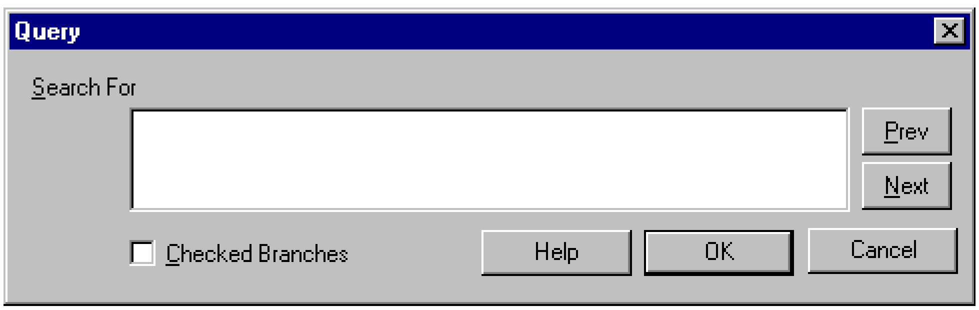
There are many terms in the lexicon of locksmithing that have not been standardized as to precisely how they appear. Thus, words may be separated by a space, hyphen, or joined together. For example, in various texts the term "strongroom" can be written as one word, two words, or hyphenated. Although uniformity was the goal throughout this text, it became impossible as we identified

some 2500 different terms that appear in trade journals and other books presented differently, with not standardization.

You are encouraged to search for terms keeping this in mind.

Search, Query

Purpose



Use Query to perform basic relevancy ranked searches on the infobase. Query also allows you to perform ***smart searches*** or ***natural language searches*** (they do not require you use or understand the advanced Folio Views™ query syntax).

Steps

To perform a simple ranked search on an infobase:

1 Choose **Query** from the **Search** menu.

•The Query dialog appears.

2 Enter the terms you wish to search for.

•The more specific your search is, the better the search results will be. For example, searching for

cases about the death penalty

is allowable, but contains "noise words" that are not relevant to the topic. A better search (assuming you were searching in an infobase of legal cases) would be

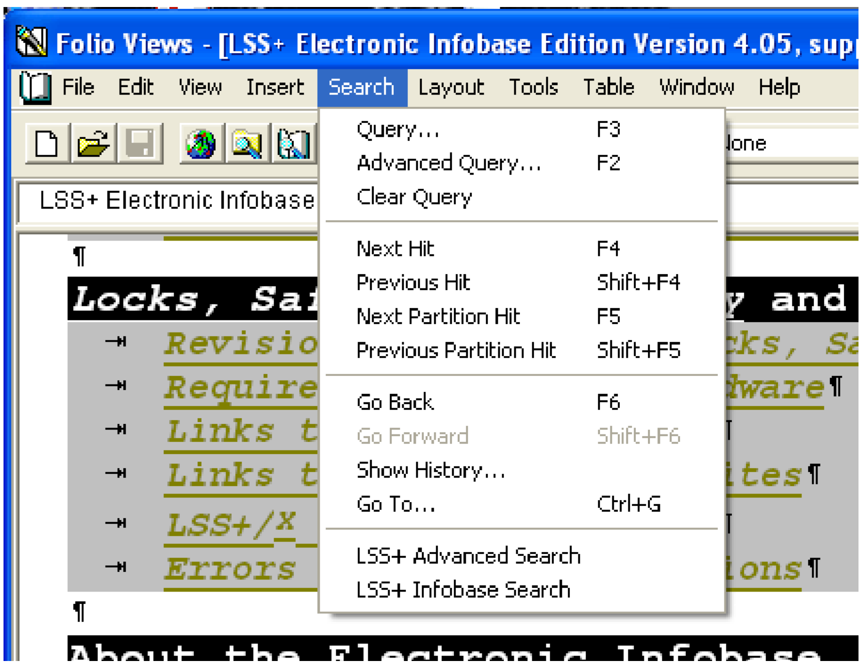
death penalty

•Note that ranked queries may also include phrases.

3 If desired, choose **Checked Branches** at the bottom of the dialog to search only the checked branches of the table of contents.

•If you have not selected any branches in the Contents pane, do not select this option. Doing so will result in 0 hits (you will be searching an empty set).

•To select branches in the Contents, click in the Contents pane, choose **Show Check Boxes** from the **View** menu, and then click in the checkboxes next to the headings in the Contents pane.



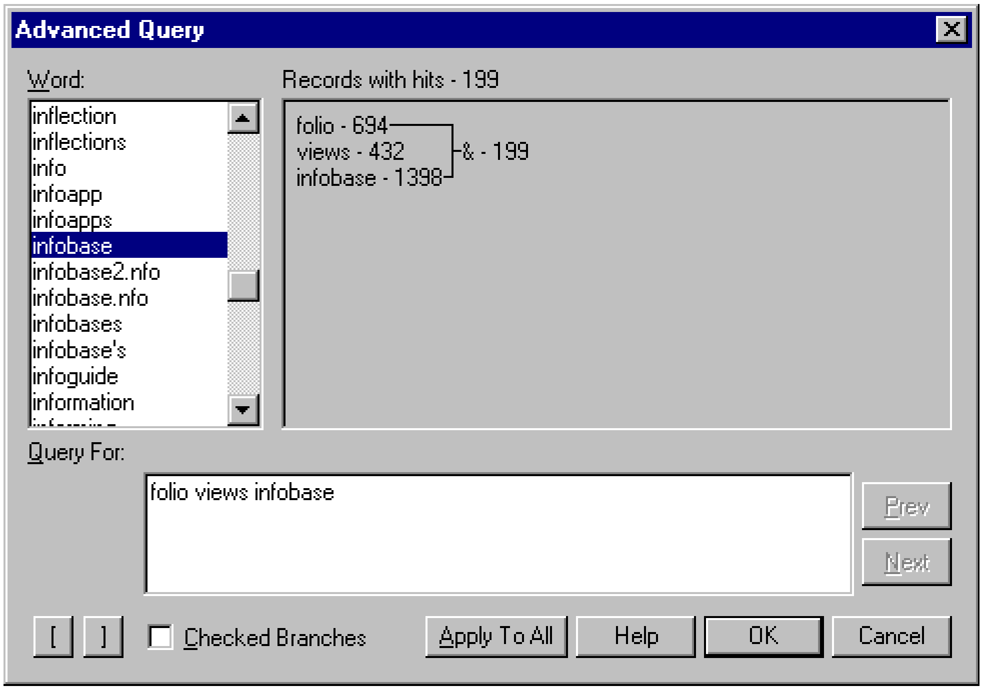
4 Choose **OK**.

•The most relevant records are listed first in the Hit List pane.

Search, Advanced Query

Purpose

Use Advanced Query to unleash the full power of the Folio Views query syntax. Advanced Query gives you complete access to the Folio Views Query Syntax. This syntax helps you focus and refine your searches through the use of Boolean operators, wildcards, proximity operators, and scope limitations. You may also use the custom query template by entering ctrl-F2.



The advanced query templates are also available through the SEARCH menu.

Searching the Infobase

To search all text in the infobase, you may utilize the default advanced query, shown below, or you may search with the LSS+ Advanced Query template, by entering CTRL-F2, or do a direct search for chapter and section number by entering CTRL-F3.

1 Choose **Advanced Query** from the **Search** menu.

•The Advanced Query dialog appears.

2 Type the words you wish to search for, separated by a space or the appropriate operator.

•You may search by keyword (not using any specific operators). For example:

paragraph formatting options

•You may search for an exact phrase. Enclose the phrase in quotation marks. For example:

"searching the infobase"

•You may use Boolean operators (and, or, not, exclusive or). For example:

search and help
search or help
search not help
search xor help

•You may use wildcards (single character, multiple character, word form, synonym). For example:

run?
run*
run%
run$

•You may use proximity operators to specify how close terms must be. For example:

"phrase search"/5

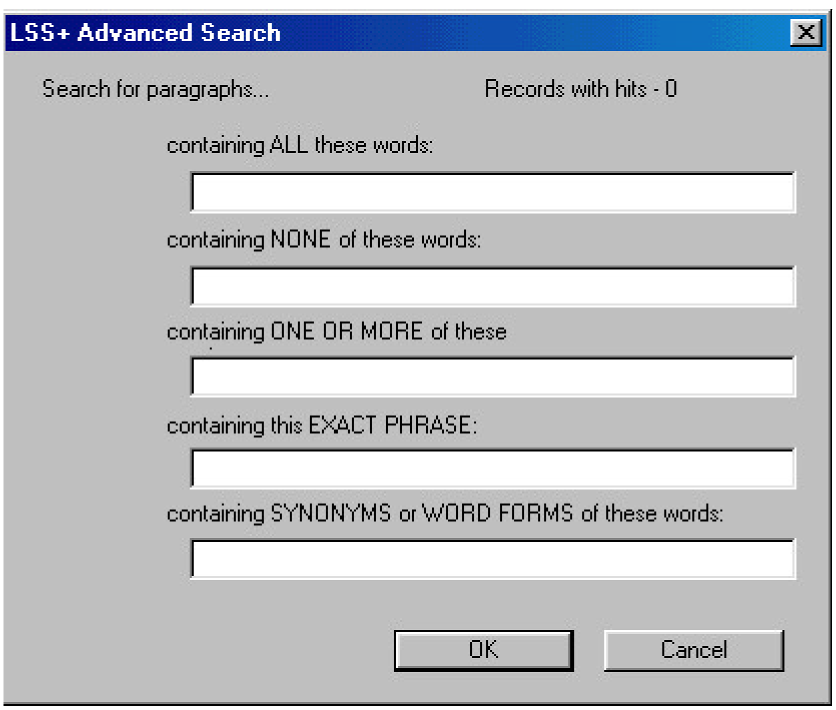
•If you wish to modify a previous query, click the **Prev** button next to the **Query For** box to display the previous query.

•Note that as you type, the Query dialog attempts to complete the word you are typing with a word contained in the infobase. If the word is correct, press the ENTER key and type the next term.

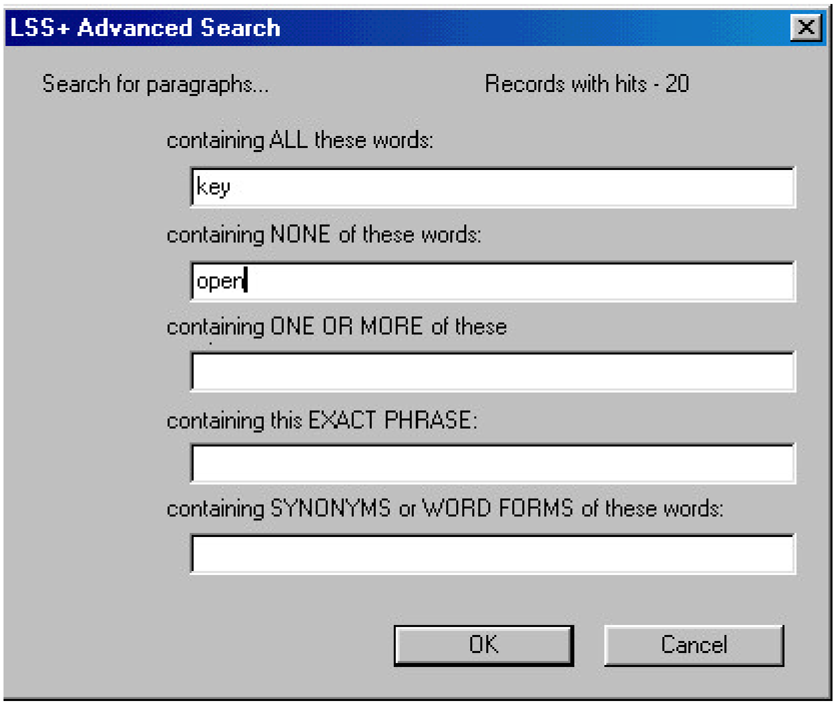
•Queries may be up to 2048 characters in length.

3 If desired, choose **Checked Branches** at the bottom of the dialog to search only the checked branches of the table of contents.

•If you have not selected any branches in the Contents pane, do not select this option. Doing so will result in 0 hits (you will be searching an empty set).



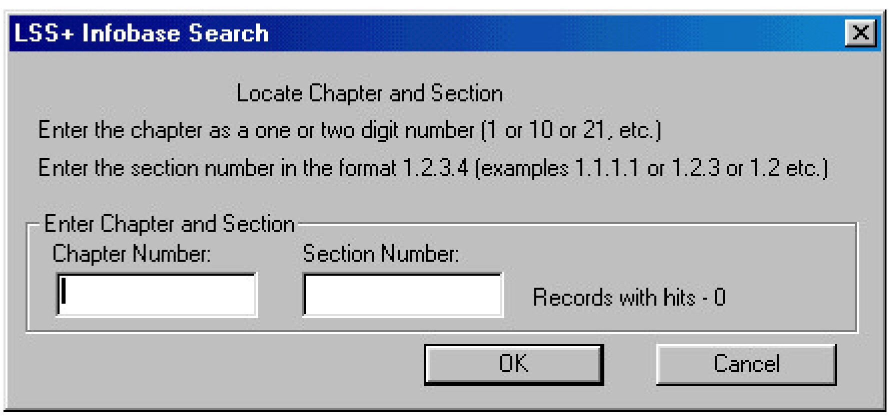
•To select branches in the Contents pane, click in the Contents pane, choose **Show Check Boxes** from the **View** menu, and then click in the checkboxes next to the headings in the Contents pane.



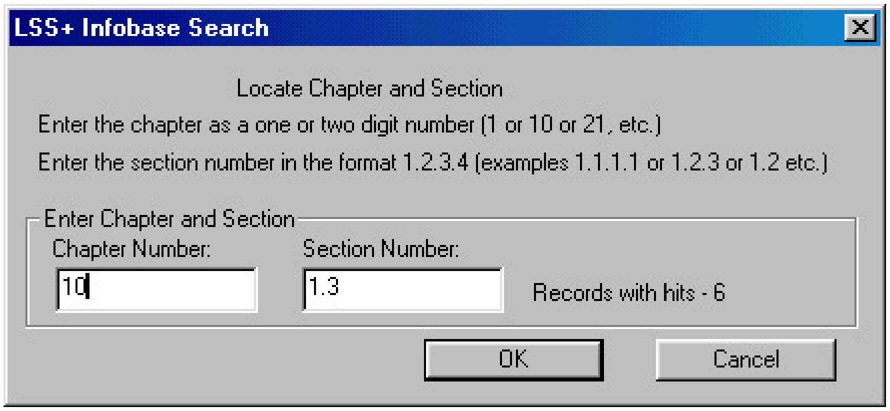
4 Choose **OK** to apply the search to the current infobase.

•Choose **Apply to All** to apply the search to all open infobases.

LSS+ Query for Advanced Search



Enter CTRL-F2 to utilize this search tool. You may enter information in one or more search fields for a narrowed or limited query. Shown is the blank template, and a query that contains the word KEY, but not the word OPEN. This search returned a total of 20 hits. You may view each hit by first pressing ENTER, then F4 to view the next hit, or SHIFT-F4 for the previous hit. You may also switch to CONTENTS VIEW, BROWSE VIEW, OR ALL VIEW to see all of the hits.



LSS+ Query to search for Chapter and Section directly.

Enter CTRL-F3 to utilize this search tool.

This example shows a blank template, and one that is running the search for Chapter 10, section 1.3.

32 (Popup - CREATING AND USING SHADOW FILES)

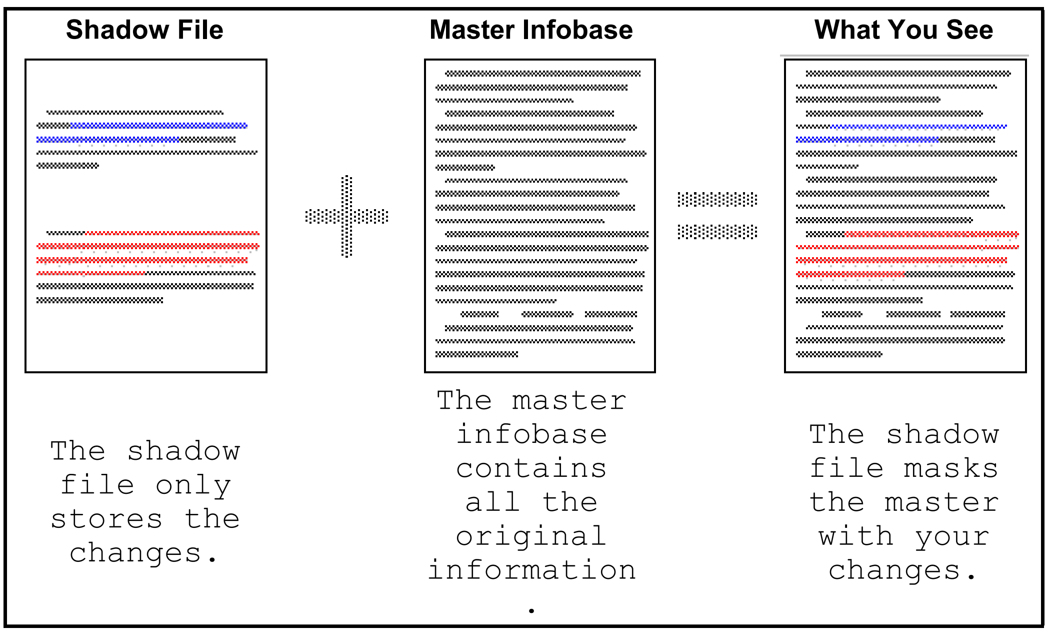
Creating a New Shadow File

To create a new shadow file:

1. Open the infobase to be shadowed.
2. Choose **New** from the **File** menu.
   •The New dialog appears.
3. Choose **File Type** and select **Folio Shadow File**.
4. Select **File Name** and enter a name for the shadow file.
   •The default extension is **.SDW**.
5. If necessary, choose **Drives** and/or **Directories** to specify where the new file should be created.
6. Choose **New** (**OK** on some platforms).

Note: Shadow files inherit the infobase password. If the infobase is password protected, then so is the shadow file.

Additional Information



The following information is presented below:

- Understanding Shadow Files
- Uses for Shadow Files

Understanding Shadow Files

A shadow file stores personal changes you make to an infobase. Much like an overlay or transparency allows you to annotate information without changing the original, a shadow file allows you to change information in a personal view of an infobase without affecting the master infobase.

When you create a shadow file, you create an overlay for an infobase. When you add notes, highlighters, or bookmarks to the shadow file, they do not appear in the original infobase (the master). When you add or remove records from the shadow file, the changes do not appear in the master. Any change you make to the shadow file only appears in the shadow file. Changes that are made to the master infobase, however, ***are*** displayed in the shadow file. This allows you to view updated information while maintaining your personal annotations. The following illustration may clarify how shadow files work:

Working in a shadow file is just like working in an infobase. Anything you can do in an infobase you can do in a shadow file (with the exception of creating a shadow file — you cannot shadow a shadow).

Uses for Shadow Files

Shadow files provide a great deal of flexibility in their application. The way you choose to implement them may depend only on your imagination. Some of the more common uses for shadow files are

- annotating infobases on CD-ROM
- legal (and other) research
- sharing comments & edits
- prototyping changes to an infobase
- updating an infobase on CD-ROM.

Annotating Infobases on CD-ROM (or Other Read-Only Media)

Shadow files were originally designed to allow you to annotate infobases stored on CD-ROM. Research has shown that using information (rather than just viewing information) provides higher learning and retention rates. With an infobase stored on CD-ROM, you can only access information, not use it. Shadow files allow you to make annotations to an infobase on CD-ROM and assist you in learning and remembering the information you use. Through a shadow file, you can add notes, highlighters, links, bookmarks, and other information to an infobase stored on CD. The information you add is placed in the shadow file, which is usually stored on your hard drive or on a network drive.

Sharing Comments / Edits

Managers of documentation departments and others who create information for others to consume are often frustrated by the review process. For some organizations and for some market-sensitive information, five or more people may have to review and approve a document before it is distributed. Coordinating the suggested edits — particularly the conflicting edits — is always challenging when done on paper.
However, the review process becomes much simpler if you make a shadow file of the document on the network and allow the reviewers to annotate it at will. Request that each reviewer make two passes on two different days. This allows the reviewers to see the comments made by each of the other reviewers. The reviewers can argue for and against changes within notes and popups within the infobase. When they have reached a consensus, you can incorporate the necessary changes in the master infobase and post it for final review.

Quick Keys

Action	*Default Keystrokes*
Open	CTRL+O
Save	CTRL+S

You must have a copy of Microsoft Windows Media Player software Version 7 (or higher) installed on your computer to view the video files. Your computer must be capable of playing WAV and mp3 files for audio, and viewing TIF files for still images.

All video files are stored in .WMV format. All patents and still images are compressed .JPG or .TIF files. Note that many of the patent files contained within the **Security.Org** website are FXS files. This is a special compression algorithm that is utilized by Symantec in their WinFax program. Contact the author if you require the viewer program for these files.

In order to view multimedia linked files on security.org, you should have a current Internet Explorer browser (version 5.0 or later) that supports java applicationsw. You will also need Windows Media Player.

Certain of the multimedia files require a security clearance and entry of a password, both for the CD/ROM and website. Contact the site administrator if you experience difficulty in registering on the site.

Some of the photograph sequences relating to picking, keying, master keying, shimming have been provided by HPC. Full descriptions of these processes are contained on the HPC Interactive Learning Series in video clips. These are highly recommended for locksmiths who are seeking additional information in the form of a tutorial.

34 (Popup - ANNUAL UPDATES AND EXPIRATION OF INFORMATOIN)

There will be periodic updates to the Electronic edition of **Locks, Safes and Security**. It is contemplated that additional materials will be added to **LSS+** and to the accompanying CDs. Your access to the supplementary materials will require the appropriate security clearance.

The data within each CD will expire one year from initialization. You must request an updated password in order to continue using the LSS+ Infobase.

All of the video segments are contained within the companion CD ROMS. They are labelled in sequence (LSS+101, 102, etc. as issued). If material has been added to a CD subsequent to the time of purchase of your version of LSS+, then you must go directly to the supplement and click on the multimedia link on that CD. As later versions of LSS+ are issued, these links will be integrated into the body of the Infobase.

35 (Popup - SUBMISSION OF INFORMATION)
Submission of information for inclusion in later editions is welcome, as are all comments, corrections, or suggestions. Please contact the author by e-mail at mwtobias@security.org, or send written inquiries to:

Marc Weber Tobias
INVESTIGATIVE LAW OFFICES
Box 90043
Sioux Falls, South Dakota 57109 USA

You may also check **Security.org** for updated contact information.

36 (Popup - SECURITY AND FILE ACCESS)
Certain ares of this CD/ROM may contain security restrictions that require a password to access information. Likewise, many areas within the **security.org** website cannot be accessed without an appropriate clearance. Please contact the site administrator for a password. You must complete the **registration** form and comply with the terms and conditions that are detailed on security.org.

You will be required to obtain a password to open certain sections of **LSS+** and **LSS+/^{x} CD/ROM**. This password is machine-specific to your computer, and will not allow you to use the CD/ROM on another device. You can only receive a password through the security.org website. NOTE: You must obtain your password while the Infobase program is opened on your computer. You will supply a code that the system generates; you will then receive another code that you must input into your computer to make the program operational. You may call 1.877.2 BUY LSS (1.877.228.9577) to register your copy of LSS+.

You must contact Investigative Law Offices (605.334.1155) or by e-mail (mwtobias@security.org) for a multiuser license.

Some material may be encoded on a DVD CD/ROM, and must be played on a DVD player. Region codes will not be required.

37 (Popup - SECURITY LEVELS AND ACCESS TO INFORMATION)
ACCESS SECURITY LEVELS and INFORMATIONT

his Infobase and multimedia supplements makes information available to a wide range of users, including the public, law enforcement investigators, crime lab technicians, forensic investigators, private security, locksmiths, and government intelligence agencies. The author shall determine the appropriate access level for each user, and shall have the right to enforce

these requirements as to the access and dissemination of information.

All information on the **LSS+** series of CD ROMs is encrypted and password protected. You must register your copy of the software before it can be accessed. The cost of the material is based upon security level. There is a specific set of disks that is provided for each security level.

Certain information relating to bypass of high security locks, equipment and technology, will be restricted to government intelligence agencies and specific law enforcement organizations only. Likewise, the description of bypass tools used to covertly enter high security locks, will be provided only to authorized agencies.

The following security levels have been established for LSS+ Infobase, to access information.

Level 1 PUBLIC: General information regarding locks and safes; on-line video; patents. No security clearance is required.

Level 2 RESTRICTED: Certain high security bypass tools that are not available for general distribution. LOCKSMITHS and QUALIFIED PRIVATE SECURITY. Access to all information regarding locks and safes, on-line video

Proof of identification required, verification of law enforcement status, agency approval, for government agencies. Membership in one or more professional organization approved by Author. Proof of licensing, bonding, or other professional certification. Membership in the following organizations will be accepted: NLA, NSO, ALOA, SAVTA, ASIS, ELF, MLA, AFTE.

Level 3 SECRET: LAW ENFORCEMENT, CRIMINALIST, AND GOVERNMENT INVESTIGATORS WITH POLICE POWERS, GOVERNMENT INTELLIGENCE, and COVERT ENTRY. Access to all information regarding locks, safes, and vaults, and bypass. Proof of identification required. Agency approval. Membership in NSO, SAVTA, ALOA or equivalent organization required for non-government agents.

38 (Popup - ABOUT THE AUTHOR, INVESTIGATIVE LAW OFFICES, AND SECURITY LABORATORIES)

Marc Weber Tobias has authored five law enforcement textbooks for Charles C. Thomas Publishers, dealing with criminal law, police communications, and security.

Tobias received a Bachelors Degree in 1970 from the University of Nebraska-Omaha, and a Juris Doctor Degree from Creighton Law School, (Omaha, Nebraska) in 1973.

He is an attorney in Sioux Falls, South Dakota, with Investigative Law Offices, P.C. As part of his practice, he routinely conducts technical fraud investigations and consults with corporations and government agencies throughout the world regarding the bypass of locks, analysis of design defects, and security liability issues.

The author has been granted two United States Patents, and several foreign derivative patents for bypass tools relating to locks.

He is a member of the Associated Locksmiths of America (ALOA), Safe and Vault Technicians Association (SAVTA), American Society for Industrial Security (ASIS), American Academy of Forensic Sciences (AAFS), International Association for Identification (IAI), American Polygraph Association (APA), and American Association of Policy Polygraphers (AAPP). He is also a technical advisor to the Association of Firearms and Tool Marks Examiners (AFTE), and a member of the International Association of Investigative Locksmiths (IAIL).

Tobias has provided technical support and investigative services involving surveillance, covert entry, interrogation, polygraph, and crime scene documentation to many law enforcement agencies throughout the world.

ABOUT INVESTIGATIVE LAW OFFICES

INVESTIGATIVE LAW OFFICES has offices in Sioux Falls, South Dakota, United States of America. We are a technology law office, focusing on the investigation of technical fraud, and related issues, in the representation of our clients. Our office provides technical support for law enforcement agencies, and consults with lock manufacturers, crime laboratories, and vendors of specialized surveillance equipment and related technologies. We also represent locksmiths, in the development and sale of sophisticated bypass tools, and related issues.

We conduct high tech surveillance operations for law enforcement organizations, law firms, business, and insurance companies, to develop evidence for civil and criminal prosecutions for fraud and related crimes.We conducts background investigations, and

have access to the most comprehensive computerized databases in the United States.

We can provide technical support and training, in the areas of covert entry, communications, computers, lie detection, and internal security investigations.
We represent clients, in order to determine potential liabilities from defective security products, and will analyze high security locks for bypass capability. We can determine ways of correcting defects, and improving upon locks, safes, and security products, including the procurement of patents.

We have experienced polygraph examiners on staff, who have been conducting lie detector examinations in criminal, civil, and security investigations for over twenty-five years. We conduct examinations, and training in the United States, and in foreign countries, upon request. We utilize Stoelting conventional polygraph instrumentation, and Axciton computerized polygraph.

Our office maintains a library of thousands of hours of videotape interrogations, for training of law enforcement agencies. We can provide technical support and training in the areas of covert entry, communications, encryption, computers, lie detection, and internal security investigations.

We conduct legal research relating to security issues, and associated technology, including product location and acquisition. We have reports available regarding many security products, and will provide contract legal research into potential defects in products.

Marc Weber Tobias and independent contractors of Investigative Law Offices are members of the following professional organizations: American Bar Association; American Polygraph Association; American Association of Police Polygraphists; American Society for Industrial Security; Associated Locksmiths of America; Safe and Vault Technicians Association; International Association for Identification; American Academy of Forensic Scientists; and Association of Firearms and Toolmarks Examiners.

The principal Attorney for Investigative Law Offices, Marc Weber Tobias, has lectured throughout the world on covert entry and surveillance. He is a member of the South Dakota and Nebraska Bars, and admitted to practice in those states, and the Eighth Circuit Court of Appeals.

Members and associates of Investigative Law Offices are members of the following professional organizations: American Bar Association; American Polygraph Association; American Association of Police Polygraphists; American Society for Industrial Security; Associated of Locksmiths of America; Safe and Vault Technicians Association; International Association for Identification; American Academy of Forensic Scientists; and Association of Firearms and Toolmarks Examiners.

ABOUT SECURITY LABORATORIES

Security Laboratories was formed by Investigative Law Offices, to bring together a number of professionals in technical disciplines relating to locks, safes, and security. We have available specialists in lock picking and covert entry, combination lock manipulation, forensics, computers, law, manufacturing, training, design of special covert entry hardware and software, law enforcement, and related areas. Security Laboratories has representatives in the United States, England, and Jersey (Channel Islands).

Our clients, both in the United States and in foreign countries, generally have special requirements involving the training and deployment of technologies relating to lock picking, safe cracking, and security. We have the capability of designing and manufacturing special bypass tools for almost any lock or locking system, and specialize in opening high security lever and pin tumbler locks. If your agency has a requirement for a special bypass tool or technique, e-mail mwtobias@security.org.

Security Laboratories is an independent group of associates who advise and consult with Investigative Law Offices, regarding security issues. Associates are not lawyers, and are not employees of Investigative Law Offices.

Contacting the Author

The author welcomes feedback from readers. His e-mail address is mwtobias@security.org. He may be contacted toll free utilizing Internet telephony or video conferencing, through **http://www.security.org**, or by writing to Charles Thomas Publishers in Springfield, Illinois.

THE REMEDIES AVAILABLE TO YOU AGAINST THE PUBLISHER UNDER THIS AGREEMENT ARE EXCLUSIVE. SOME STATES DO NOT ALLOW THE LIMITATION OR EXCLUSION OF IMPLIED WARRANTIES OR LIABILITY FOR INCIDENTAL OR CONSEQUENTIAL DAMAGES, SO THE ABOVE LIMITATIONS OR EXCLUSIONS MAY NOT APPLY TO YOU.

41 (Popup - WAIVERS AND DISCLAIMERS)

WAIVERS, CONDITIONS, and DISCLAIMERS

Information within this Infobase describes certain locks and safes, and how they may be bypassed. Specific techniques are disclosed regarding lock picking, impressioning, decoding, and manipulation. As such, the reader is cautioned that the misuse of such information may constitute a crime in certain jurisdictions.

This work is intended for use primarily by law enforcement, intelligence, and other government agencies, as well as professional locksmiths and safe technicians. It is not intended, nor shall it knowingly be distributed, to individuals who do not have a legitimate need-to-know the information contained herein.

Certain WAIVERS, CONDITIONS, and DISCLAIMERS apply to this material, and the reader. The reader is granted a non-exclusive license to use the information and graphics contained herein, for personal use. They may not be reproduced in any form, without the express consent of the Author. The information contained herein is covered by the copyright laws of the United States, and international conventions.

If you do not agree to the specified WAIVERS, CONDITIONS, AND DISCLAIMERS, you should return this CD ROM set, for a full refund. Acceptance of all WAIVERS, CONDITIONS, AND DISCLAIMERS shall be acknowledged by your possession and use of this CD set. Your LICENSE is based upon such ACCEPTANCE.

The term AUTHOR shall include and refer to Marc Weber Tobias, as well as the Publisher, and any person or entity who has provided any information or materials to the author for the preparation of this book or CD/ROM.

The term INFORMATION, shall describe and apply to all data, graphics, illustrations, diagrams, and photographs contained within this text, referenced in any CD/ROM or web site, or to any direct or indirect information or conclusions which can be inferred or deduced from such material.

READER shall be defined as the purchaser, user, or other individual or entity who, through any means, obtains INFORMATION, in any form, from this CD ROM set.

The reader understands, acknowledges, and agrees to the following WAIVERS, CONDITIONS, and DISCLAIMERS for the use, in any form whatsoever, of the INFORMATAOIN contained within this CD ROM set.

WAIVERS AND CONDITIONS

1. The AUTHOR assumes no liability whatsoever, for the use or misuse of any information contained herein;

2. No product endorsement or rating is intended or implied, unless specifically noted;

3. The AUTHOR assumes no liability whatsoever for the reliance, by any READER, with respect to the security rating of any product, which causes any loss of any kind;

4. Technical information and advice is believed accurate at the time of publication. The AUTHOR does not warrant the accuracy or reliability of any technical information or advice, and disclaims any liability based upon the reliance by any READER of such information.

5. AUTHOR assumes no responsibility to inform its readers of any inaccuracy that may be discovered after publication;

6. READER shall have no cause of action whatsoever against AUTHOR for the use of any INFORMATION contained herein.

DISCLAIMERS

1. The AUTHOR is not affiliated with any manufacturer, company, or organization, nor has any economic or contractual relationship with any vendor or product described in this CD ROM set;

2. All statements or opinions expressed herein with respect to any product, technique, or generic classification are those of the AUTHOR alone, and should be construed as opinions only;

3. AUTHOR does not endorse, warrant, or guarantee any product in this CD ROM set. The mere appearance within this text should not be so considered;

4. Bypass information is lock specific. A manufacturer may make changes to frustrate bypass techniques detailed herein which are unknown to the AUTHOR, or which have occurred since publication, or in different models of the lock;

5. The use or misuse of any of the INFORMATION and techniques described within this CD ROM set may be illegal by certain individuals in one or more jurisdictions. The AUTHOR assumes no liability for the use or misuse of any INFORMATION or procedures described herein, and in no way encourages the use of such information in cases where such may be unlawful;

6. Any statements or opinions by the AUTHOR, with respect to

the compromise of security of any product, is based upon data developed by the author or others, or known within the security and locksmithing industry. Any tests shall have been based on sample products that have been purchased from the manufacturer by the AUTHOR, or supplied to the AUTHOR by the manufacturer.

7. AUTHOR makes no representation that he has tested every product of any specific manufacturer described herein. AUTHOR further makes no representation that any product so tested is representative of all other products of any manufacturer.

8. The bypass of any product described within this text may reflect manufacturing tolerance errors, which may or may not be common to all locks or other security devices. Because it is impossible to test all such devices, there is no way to determine if all such devices exhibit the same characteristics. The READER should therefore draw their own conclusions as to the security and integrity of any product.

44 (Popup - FORCED ENTRY TOOL VENDORS)

Several vendors for forced entry tools have been identified within this Infobase. The following manufacturers are recommended by the author, based upon the quality and diversity of their products.

MBA
Mark Bates
101 Edgewood Plaza Drive
Nicholasville, Kentucky 40356
1.888.MBA.5495
www.mbausa.com

HPC, INC.
3999 25th Avenue
Box 2093
Schiller Park, Illinois 60176
1.847.671.6280
www.hpcworld.com

SIGMA
David Nightingale
135 Snargate Street
Dover, Kent CT17 9DA
United Kingdom
+441304.205050

IOWA-AMERICAN
Industrial Park, Box 517
Osceola, Iowa 50213
1.515.342.6091

LOCKMASTERS, INC.
5085 Danville Road
Nicholasville, Kentucky 40356
1.859.885.6041
www.lockmasters.com

45 (Popup - SAFES AND VAULTS: REFERENCE WORKS)
A comprehensive bibliography appears within this Infobase. There are many other reference works that are available to the locksmith trade. These can be found at The **National Locksmith** Publishing Company, HPC, INC LEARNING CENTER, **LOCKMASTERS**, MBA, ALOA, and ASIS.

An extremely comprehensive set of drill-point diagrams for all major combination locks and safes is available from Ed Willis, through **MBA**.

46 (Popup - TRAINING AND SEMINARS)
Training and seminars in covert and forced entry are conducted for law enforcement, security, and intelligence agencies by the following organizations and individuals:

Marc Weber Tobias
INVESTIGATIVE LAW OFFICES and SECURITY LABORATORIES
300 S. Phillips, Suite 202
Sioux Falls, South Dakota 57104 United States
1.605.334.1155
mwtobias@security.org

John Falle
FALLE SAFE SECURITIES
Jersey, United Kingdom
+441534 280091

Mark Bates
MBA
101 Edgewood Plaza Drive
Nicholasville, Ky 40356

HPC LEARNING CENTER
3990 25th Avenue, Box 2093
Schiller Park, Illinois 60176

SIGMA
135 Snargate Street
Dover, Kent CT17 9DA
United Kingdom

LOCKMASTERS, INC.
5085 Danville Road
Nicholasville, Ky 40356

ALOA
3003 Live Oak Street
Dallas, Texas 75204

47 (Popup - SECURITY ANALYSIS OF PRODUCTS FOR BYPASS)

The author and associates routinely analyze locks, safes, and security systems for clients, manufacturers, and government agencies. If you have a need of such services, please contact the author at **Investigative Law Offices** at 1.605.334.1155, or by e-mail at mwtobias@security.org. Please view the detailed information about the author found at **www.security.org**, and within this Infobase.

48 (Popup - LEGAL SERVICES BY INVESTIGATIVE LAW OFFICES)

Legal services for locksmiths and manufacturers are provided by **Investigative Law Offices.** These relate to product analysis for defects and bypass techniques, product design, and security consultation. Please contact the author at mwtobias@security.org.

49 (Popup - HISTORICAL REFERENCE TO LOCKS)

There is an excellent treatment of the history of the first locks in the George Price book contained within this Infobase.

50 (Popup - WOLVERHAMPTON)

51 (Popup - ASSOCIATED LOCKSMITHS OF AMERICA)

Associated Locksmiths of America, Inc. (ALOA)
3003 Live Oak Street
Dallas, TX 75204

52 (Popup - CHANGE KEY SETS)

Change key sets are available from:

KEELER, INC.
12931 Shackelforfd Lane
Garden Grove, CA 92841
714 636 5657
www.safe@keelex.com

53 (Popup - HARDWARE SCHEDULE)

The information on the hardware schedule should include:

manufacturer
type of hardware
finish
size
location
keying schedule for each locking device

54 (Popup - LEVELS OF KEYING - STANDARD KEY CODING SYSTEM)
TWO LEVEL SYSTEM
Master key MK
Change key CK

THREE LEVEL SYSTEM
Grand master GMK
Master key MK
Change key CK

FOUR LEVEL SYSTEM
Great grand master key GGMK
Grand master key GMK
Master key MK
Change key CK

FIVE LEVEL SYSTEM
Great great grand master key GGGMK
Great grand master GGMK
Grand master GMK
Master key MK
Change key CK

SIX LEVEL SYSTEM
Great great grand master key GGGMK
Great grand master GGMK
Grand master GMK

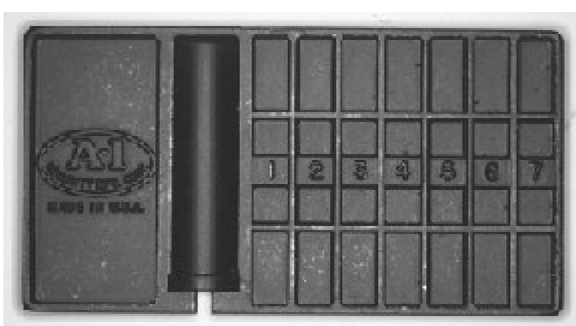
55 (Popup - US PATENT 2030837)
Page: 1,2,3,4

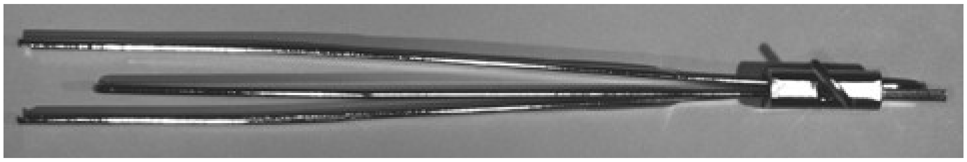
56 (Popup - FIGURE 4-3. HPC CODEMAX KEY MACHINE)
The HPC Codemax key machine is one of the most popular and versatile cutters on the market.



57 (Popup - FIGURE 4-5. PLUG HOLDER)

A plug holder retains the plug within a fixture during maintenance and pinning of the lock.

58 (Popup - FIGURE 4-6. SET-UP TRAY)



A setup tray is used to store all springs and pins during disassembly of a pin tumbler lock.

59 (Popup - FIGURE 4-7. TWEEZERS)

Special tweezers are utilized for the removal and insertion of pins within a cylinder. The type shown is produced by HPC, and

allows for the precise depression and control of an individual pin.

60 (Popup - US PATENT 1307379)

Page: 1,2,3,4,5,6,7,8
69 (Popup - BASIC OXYGEN FURNACE EXPLANATION)
In the basic oxygen process, the fuel is fed by a high-pressure stream of nearly pure oxygen blown into the furnace at supersonic speed. The oxygen combines with carbon and other unwanted elements and rapidly burns out impurities, converting the pig iron into steel.

70 (Popup - USE OF ELECTRIC ARC FURNACES)
In some furnaces, electricity instead of fire supplies the heat. Because refining conditions in such a furnace can be strictly regulated, electric furnaces are particularly valuable for producing steels that must be made to exacting specifications.

71 (Popup - DEFINITION OF ELEMENT)
element (èl´e-ment) noun

1. A fundamental, essential, or irreducible constituent of a composite entity.

2. elements. The basic assumptions or principles of a subject.

3. Chemistry & Physics. A substance composed of atoms having an identical number of protons in each nucleus. Elements cannot be reduced to simpler substances by normal chemical means.

4. One of four substances, earth, air, fire, or water, formerly regarded as a fundamental constituent of the universe.

[Middle English, from Old French, from Latin elementum.]

Synonyms: element, component, constituent, factor, ingredient. The central meaning shared by these nouns is "one of the individual parts of which a composite entity is made up."

72 (Popup - DEFINITION OF ATOM)

atomize

atomize (àt´e-mìz´) verb, transitive
atomized, atomizing, atomizes

1. To reduce to or separate into atoms.

2. To reduce to tiny particles or a fine spray.

3. To break into small fragments.

4. To subject to bombardment with atomic weapons.

- at´omiza´tion (-î-zâ´shen) noun

73 (Popup - DEFINITION OF COMPOUND)

compound (kòm-pound´, kem-, kòm´pound´) verb
compounded, compounding, compounds verb, transitive

1. To combine so as to form a whole; mix.

2. To produce or create by combining two or more ingredients or

parts: pharmacists compounding prescriptions.

verb, intransitive

1. To combine in or form a compound.

2. To come to terms; agree.

adjective (kòm´pound´, kòm-pound´, kem-)

1. Consisting of two or more substances, ingredients, elements, or parts.

2. Botany. Composed of more than one part.

noun (kòm´pound´)
Abbr. comp., cpd.

1. A combination of two or more elements or parts. See synonyms at mixture.

2. Chemistry. A pure, macroscopically homogeneous substance consisting of atoms or ions of two or more different elements in definite proportions that cannot be separated by physical means. A compound usually has properties unlike those of its constituent elements.

[Alteration of Middle English compounen, from Old French componre, compondre, to put together, from Latin componere. See component.]
- compound´able adjective
- compound´er noun

74 (Popup - DEFINITION OF MOLECULE)

molecule (mòl´î-ky¡l´) noun
Abbr. mol.

1. The smallest particle into which an element or a compound can be divided without changing its chemical and physical properties; a group of like or different atoms held together by chemical forces.

2. A small particle; a tiny bit.

[French molécule, from New Latin molêcula, diminutive of Latin molês, mass.]

75 (Popup - DEFINITION OF MIXTURE)

mixture (mîks´cher) noun

1. a. The act or process of mixing: an alloy made from the mixture of two metals. b. The condition of being mixed: the inevitable mixtures of urban neighborhoods.

2. Something produced by mixing.

3. Chemistry. A composition of two or more substances that are not chemically combined with each other and are capable of being separated.

[Middle English, from Old French, from Latin mixtúra, from mixtus, past participle of miscêre, to mix.]

Synonyms: mixture, blend, admixture, compound, composite, amalgam. These nouns refer to a combination produced by mixing. Mixture has the widest application: a mixture of tea and honey; yarn that is a mixture of nylon and cotton. "He showed a curious mixture of eagerness and terror" (Francis Parkman). Blend denotes an intimate, harmonious mixture in which the original components lose their distinctness: Admixture suggests that one of the components of the mixture is dissimilar to the others: The essential oil in the perfume contains a large admixture of alcohol.

A **compound** is a combination of elements or parts that together constitute a new and independent entity: The word houseboat is a compound. Creative genius is a compound made up of exceptional intellect and superior imagination. A **composite** usually lacks the unity of a compound since the components may not wholly lose their identities: The suite is a composite of themes for various parts of the opera. **Amalgam** implies an intimate union of diverse elements likened to an alloy of mercury and another metal.

76 (Popup - DEFINITION OF SOLUTE)

solute (sòl´y¡t, so´l¡t) noun

A substance dissolved in another substance, usually the component of a solution present in the lesser amount.

adjective
Being in solution; dissolved.

[From Middle English, loose, porous, from Latin solútus, past participle of solvere, to loosen.]

77 (Popup - DEFINITION OF SOLVENT)

solvent (sòl´vent, sôl´-) adjective

1. Capable of meeting financial obligations.

2. Chemistry. Capable of dissolving another substance.

noun

1. Chemistry. a. A substance in which another substance is dissolved, forming a solution. b. A substance, usually a liquid, capable of dissolving another substance.

2. Something that solves or explains.

[French, from Latin solvêns, solvent-, present participle of solvere, to loosen. See solve.]
- sol´vency noun

78 (Popup - DEFINITION OF SOLUTIONS)

Solutions, evenly distributed mixtures of two or more substances. The substance present in largest quantity is called the **solvent.** The substance in the smallest quantity is called the **solute.** Unlike colloids and suspensions, solutions appear the same throughout even under a microscope, and the solute cannot be separated by filtration. Salts, acids, and bases ionize when they are dissolved in water (see Ionization).

Certain metals are soluble in one another in the liquid state and solidify with the mixture of atoms preserved.

Some liquids can dissolve in each other in any proportion; others

have limits. If a solute added to a solution above a certain amount will not dissolve, the solution is called saturated. For most substances, solubility increases with increasing temperature of the solvent. In general, molecules that are structurally similar to the molecules of the solvent have the highest solubility.

When a solute is added to a solvent, several physical properties of the solvent change. Its boiling point rises and its freezing point lowers with increasing concentrations of solute.

79 (Popup - DEFINITION OF ALLOY)

alloy (àl´oi´, e-loi´) noun

1. A homogeneous mixture or solid solution of two or more metals, the atoms of one replacing or occupying interstitial positions between the atoms of the other: Brass is an alloy of copper and zinc.

2. A mixture; an amalgam: "Television news has . . . always been an alloy of journalism and show business" (Bill Moyers).

3.The relative degree of mixture with a base metal; fineness.
4.Something added that lowers value or purity.

verb, transitive
alloyed, alloying, alloys (e-loi´, àl´oi´)

1.To combine (metals) to form an alloy.

2.To combine; mix: idealism that was alloyed with political skill.

3.To debase by the addition of an inferior element.

[Alteration (influenced by French aloi), of obsolete allay, from Middle English alay, from Old North French allai, from allayer, to alloy, from Latin alligâre, to bind : ad-, ad- + ligâre, to bind.]

80 (Popup - DEFINITION OF CRYSTAL)

crystallize

crystallize also crystalize (krîs´te-lìz´) verb
crystallized also crystalized crystallizing crystalizing
crystallizes crystalizes verb, transitive

1. To cause to form crystals or assume a crystalline structure.

1. To assume a crystalline form.

2. To take on a definite, precise, and usually permanent form.
- crys´talliz´able adjective
- crys´talliza´tion (-lî-zâ´shen) noun
- crys´talliz´er noun

81 (Popup - DEFINITION OF ACICULAR)

acicular (e-sîk´ye-ler) adjective
Having the shape of a needle: acicular crystals.

82 (Popup - DEFINITION OF ALLOYING)

alloy (àl´oi´, e-loi´) noun

1.A homogeneous mixture or solid solution of two or more metals, the atoms of one replacing or occupying interstitial positions between the atoms of the other: Brass is an alloy of copper and zinc.

2. The relative degree of mixture with a base metal; fineness.

3. Something added that lowers value or purity.

verb, transitive
alloyed, alloying, alloys (e-loi´, àl´oi´)

1. To combine (metals) to form an alloy.

3. To debase by the addition of an inferior element.

[Alteration (influenced by French aloi), of obsolete allay, from Middle English alay, from Old North French allai, from allayer, to alloy, from Latin alligâre, to bind : ad-, ad- + ligâre, to bind.]

83 (Popup - TUNGSTEN)

Tungsten
element 74

84 (Popup - MOLYBDENUM)

Molybdenum
element 42

85 (Popup - COBALT)

Cobalt
element 27

86 (Popup - CARBON)

Carbon
element 6

87 (Popup - CHROMIUM)

Chromium
element 24

88 (Popup - VANADIUM)

Vanadium
element 23

89 (Popup - ELEMENTS USED TO ALTER THE CHARACTERISTICS OF METALS AND FOR THE PRODUCTION OF LOCKS AND SAFES)

Cobalt: used in superalloys for jet engines, chemicals (paint driers, catalysts, magnetic coatings), permanent magnets, and cemented carbides for cutting tools. More than 90% of the world's cobalt is produced in Canada, Finland, Norway, Russia, Zaire, and Zambia. The U.S. uses about one-third of total world consumption. Although its resources are relatively large, the U.S. has not produced cobalt since 1971; most U.S. cobalt resources are low grade, and production from these deposits is not economically feasible.

Columbium: used mostly as an additive in steelmaking and in superalloys. Brazil and Canada are the world's leading columbium raw materials (feedstock) producers. There is no U.S. columbium mining industry.

Copper: uses of copper in the U.S. are in building construction (42%), electrical and electronic products (24%), industrial machinery and equipment (13%), transportation (11%), and consumer and general products (10%). The leading producer is Chile, followed by the U.S., Canada, Russia, Australia, Zambia, Poland, and China. Principal mining states are Arizona, New Mexico, and Utah.

Gold: used in the U.S. in jewelry and the arts (70%), electronics and other industries (23%), and dentistry (7%). South Africa has about half the world's resources; significant quantities are also present in the U.S., Australia, Canada, the former Soviet Union, and Brazil. Gold is mined in nearly all the Western U.S. states and in Alaska.

Iron ore: the source of primary iron for the world's iron and steel industries. Major iron ore producers include Australia, Brazil, China, and the former Soviet Union.

Lead: the U.S., Australia, China, Peru, and Canada are the world's largest producers of lead. Transportation accounts for the major end use in the U.S., with 85% used in batteries, bearings, casting metals, and solders. Other uses include emergency power supply batteries, construction sheeting, sporting ammunition, and power cable coverings. The U.S. produces and consumes more than 20% of the world's lead metal.
Manganese: essential to iron and steel production. The U.S., Japan, and Western Europe have exhausted nearly all of their economically minable manganese. South Africa and the former Soviet Union have about 80% of the world's reserves.
Nickel: vital to the stainless steel industry; played a key role in the development of the chemical and aerospace industries. Leading producers include Russia, Canada, Australia, New Caledonia, and Indonesia.

Platinum-Group Metals: the platinum group consists of 6 closely related metals: platinum, palladium, rhodium, ruthenium, iridium, and osmium. They commonly occur together in nature and are among the scarcest of the metallic elements. They are consumed in the U.S. by the following industries: automotive, electrical and electronic, chemical, and dental and medical. The automotive, chemical, and petroleum-refining industries use platinum-group metals mainly as catalysts. The former Soviet Union and South Africa have nearly all the world's reserves.
Silver: used in the following U.S. industries: photography, electrical and electronic products, sterlingware, electroplated ware, and jewelry. Silver is mined in more than 60 countries. Nevada produces more than 50% of U.S. silver, Idaho 12%.
Tantalum: a refractory metal with unique electrical, chemical, and physical properties; used in the U.S. mostly to produce electronic components, mainly tantalum capacitors. Australia, Brazil, and Canada are the leading tantalum raw-material producers. There is no U.S. tantalum mining industry.
Titanium: as a metal, titanium is used mostly in commercial and

military aerospace applications. Titanium metal is produced primarily in China, Japan, Kazakstan, Russia, and the U.S.

Vanadium: used as an alloying element in steel and aerospace titanium alloys, as a catalyst in the production of maleic and phthalic anhydride, and in the production of sulfuric acid. China, South Africa, and Russia are the world's largest producers of vanadium-bearing ores and concentrates.

Zinc: used as a protective coating on steel, as diecastings, as an alloying metal with copper to make brass, and as a component of chemical compounds in rubber and paints. It is mined in more than 50 countries. Canada is the leading producer, followed by China, Australia, Peru, the U.S., and Mexico. In the U.S., mine production comes mostly from Alaska, Tennessee, New York, and Missouri.

90 (Popup - TENSILE STRENGTH)

tensile strength (noun)

strength: load-bearing capacity, tensile strength

91 (Popup - DEFINITION OF STRETCHING OR PULLING)

stretch (strèch) verb
stretched, stretching, stretches verb, transitive

1. To lengthen, widen, or distend: stretched the sweater out of shape.

2. To cause to extend from one place to another or across a given space: stretched the banner between two poles.

3. To make taut; tighten: stretched the tarpaulin until it ripped.

verb, intransitive

1. To become lengthened, widened, or distended.

2. To extend or reach over a distance or an area or in a given direction: "On both sides of us stretched the wet plain" (Ernest Hemingway).

noun

1. The act of stretching or the state of being stretched.

2. The extent or scope to which something can be stretched; elasticity.

[Middle English strecchen, from Old English streccan.]
- stretch´abil´ity noun
- stretch´able adjective

92 (Popup - DEFINITION OF COMPRESSION)

compress (kem-près´) verb, transitive
compressed, compressing, compresses

1. To press together: compressed her lips.

2. To make more compact by or as if by pressing. See synonyms at contract.

noun (kòm´près´)

1. A machine for compressing material.

[Middle English compressen, from Old French compresser, from Late Latin compressâre, frequentative of Latin comprimere : com-, com- + premere, to press.]

93 (Popup - DEFINITION OF SHEAR)

shear (shîr) verb
sheared, sheared or shorn (shôrn, shorn) shearing, shears verb, transitive

To cut with or as if with shears: shearing a hedge.

verb, intransitive
1. To use a cutting tool such as shears.

2. To move or proceed by or as if by cutting: shear through the wheat.

3. Physics. To become deformed by forces tending to produce a shearing strain.

noun

1. Physics. a. An applied force or system of forces that tends to produce a shearing strain. Also called shearing stress, shear stress. b. A shearing strain.

[Middle English scheren, from Old English sceran. N., from Middle English shere, from Old English scêar.]
- shear´er noun

94 (Popup - DEFINITION OF FATIGUE)

fatigue (fe-têg´) noun

1. Physical or mental weariness resulting from exertion.

2. The weakening or failure of a material, such as metal or wood, resulting from prolonged stress.

verb
fatigued, fatiguing, fatigues verb, transitive

1. To create fatigue in (a metal or other material).

[French, from Old French, from fatiguer, to fatigue, from Latin fatìgâre.]

95 (Popup - DEFINITION OF IMPACT)

impact (îm´pàkt´) noun

1. The striking of one body against another; collision.

2. The force or impetus transmitted by a collision.

3. The effect or impression of one thing on another: still gauging the impact of automation on the lives of factory workers.

verb
impacted, impacting, impacts (îm-pàkt´) verb, transitive

1. To pack firmly together.

2. To strike forcefully: meteorites impacting the lunar surface.

[From Latin impâctus, past participle of impingere, to push against. See impinge.]
- impac´tion noun

Synonyms: impact, repercussion. The central meaning shared by these nouns is "a strong effect exerted by one person or thing on another": the far-reaching impact of an oil embargo; a strike that had dire repercussions. See also synonyms at collision.

96 (Popup - DEFINITION OF FLEXURE OR BENDING)

flexure (flèk´sher) noun

1. A curve, turn, or fold, such as a bend in a tubular organ: a flexure of the colon.

2. The act or an instance of bending or flexing; flexion.
- flex´ural adjective

97 (Popup - DEFINITION OF TORSION OR TWISTING)

torsion (tôr´shen) noun

1.a. The act of twisting or turning. b. The condition of being twisted or turned.

2. The stress or deformation caused when one end of an object is twisted in one direction and the other end is held motionless or twisted in the opposite direction.

[Middle English torcion, wringing pain in the bowels, from Old French torsion, from Late Latin torsio, torsion-, a wringing pain, variant of Latin tortio, from tortus, past participle of torquêre, to twist. See torsade.]
- tor´sional adjective
- tor´sionally adverb

98 (Popup - DEFINITION OF DUCTILE)

ductile (dùk´tel, -tìl´) adjective

1. Easily drawn into wire or hammered thin: ductile metals.

2. Easily molded or shaped. See synonyms at malleable.

[Middle English ductil, from Old French, from Latin ductilis, from ductus, past participle of dúcere, to lead.]
- ductil´ity (-tîl´î-tê) or duc´tilibil´ity (-le-bîl´î-tê) noun

99 (Popup - DEFINITION OF BRITTLE)

brittle (brît´l) adjective
brittler, brittlest

1.a. Likely to break, snap, or crack, as when subjected to pressure: brittle bones. b. Easily disrupted: a brittle relationship between husband and wife. See synonyms at fragile.

[Middle English britel, probably from Old English *brytel, from bryttian, to shatter.]
- brit´tlely (brît´l-ê) adverb
- brit´tleness noun

100 (Popup - DEFINITION OF WEAR)

wear (wâr) verb
wore (wôr, wor) worn (wôrn, worn) wearing, wears verb, transitive

1. To damage, diminish, erode, or consume by long or hard use, attrition, or exposure. Often used with away, down, or off: rocks worn away by the sea; shoes worn down at the heels.

2. To produce by constant use, attrition, or exposure: eventually wore hollows in the stone steps.

3. To bring to a specified condition by long use or attrition: wore the clothes to rags; pebbles worn smooth.

verb, intransitive

1. To break down or diminish through use or attrition: The rear tires began to wear.

noun

1. Gradual impairment or diminution resulting from use or attrition.

2. The ability to withstand impairment from use or attrition: The engine has plenty of wear left.

- phrasal verb.
wear down

To break down or exhaust by relentless pressure or resistance.
wear off

To diminish gradually in effect: The drug wore off.
wear out

1. To make or become unusable through long or heavy use.

2. To use up or consume gradually.

3. To exhaust; tire.

[Middle English weren, from Old English werian.]
- wear´er noun

101 (Popup - DEFINITION OF CORROSION)

corrosive (ke-ro´sîv, -zîv) adjective

1. Having the capability or tendency to cause corrosion: a corrosive acid.

2. Gradually destructive; steadily harmful: corrosive anxiety; corrosive increases in prices; a corrosive narcotics trade.

noun

A substance having the capability or tendency to cause corrosion.
- corro´sively adverb

- corro´siveness noun

102 (Popup - DEFINITION OF VERDIGRIS)

verdigris (vûr´dî-grês´, -grîs´, -grê´) noun

1. A blue or green powder consisting of basic cupric acetate used as a paint pigment and fungicide.

2. A green patina or crust of copper sulfate or copper chloride formed on copper, brass, and bronze exposed to air or seawater for long periods of time.

[Middle English vertegrez, from Old French verte grez, alteration of vert-de-Grice : verd, green. See verdure + de, of (from Latin dê). See de- + Grice, Greece.]

103 (Popup - DEFINITION OF DEFORMATION)

deform (dî-fôrm´) verb
deformed, deforming, deforms verb, transitive

1. To spoil the natural form of; misshape: a body that had been deformed by disease.

2. Physics. To alter the shape of by pressure or stress.

verb, intransitive
To become deformed. See synonyms at distort.

[Middle English deformen, from Old French deformer, from Latin dêformâre : dê-, de- + forma, form.]
- deform´abil´ity noun
- deform´able adjective

104 (Popup - DEFINITION OF CLEAVAGE)

cleavage (klê´vîj) noun

1. The act of splitting or cleaving.

2. The state of being split or cleft; a fissure or division.

3. Mineralogy. The splitting or tendency to split of a crystallized substance along definite crystalline planes, yielding smooth surfaces.

105 (Popup - DEFINITION OF QUENCHING)

quench (kwènch) verb, transitive
quenched, quenching, quenches

1. To put out (a fire, for example); extinguish.

2. To cool (hot metal) by thrusting into water or other liquid.

[Middle English quenchen, from Old English âcwencan.]
- quench´able adjective
- quench´er noun
- quench´less adjective

106 (Popup - DEFINITION OF ANNEALING)

anneal (e-nêl´) verb
annealed, annealing, anneals verb, transitive

1. To subject (glass or metal) to a process of heating and slow cooling in order to toughen and reduce brittleness.

2. To strengthen or harden.

verb, intransitive

To become strengthened or hardened: "the time she needed for opinion to anneal around her policy" (Alexander M. Haig, Jr.).

[Middle English anelen, from Old English onælan, to set fire to : on, on. See on + ælan, to kindle.]

107 (Popup - DEFINITION OF NORMALIZING)

normal (nôr´mel) adjective

1. Abbr. n, N, n. Chemistry. a. Designating a solution having one gram equivalent weight of solute per liter of solution. b.

Designating an aliphatic hydrocarbon having a straight and unbranched chain of carbon atoms.

[Middle English, from Late Latin normâlis, from Latin, made according to the square, from norma, carpenter's square.]
- nor´mally adverb

108 (Popup - Popup)

temper (tèm´per) verb
tempered, tempering, tempers verb, transitive

2. To bring to a desired consistency, texture, hardness, or other physical condition by or as if by blending, admixing, or kneading: temper clay; paints that had been tempered with oil.

3. To harden or strengthen (metal or glass) by application of heat or by heating and cooling.

verb, intransitive
To be or become tempered.

noun

1. a. The condition of being tempered. b. The degree of hardness and elasticity of a metal, chiefly steel, achieved by tempering.

2. A modifying substance or agent added to something else.

[Middle English temperen, from Old English temprian, from Latin temperâre, probably from temper-, variant of tempor-, stem of tempus, time, season.]
- tem´perabil´ity noun
- tem´perable adjective
- tem´perer noun

109 (Popup - DEFINITION OF CARBURIZING)

carburize (kär´be-rìz´, -bye-) verb, transitive
carburized, carburizing, carburizes

1. To treat, combine, or impregnate with carbon, as when

casehardening steel.

2. To carburet.

[carbur(et) + -ize.]
- car´buriza´tion (-ber-î-zâ´shen, -byer-) noun

110 (Popup - DEFINITION OF CYANIDING)

cyanide (sì´e-nìd´) noun also cyanid (-nîd)

Any of various salts or esters of hydrogen cyanide containing a CN group, especially the extremely poisonous compounds potassium cyanide and sodium cyanide.

verb, transitive
cyanided, cyaniding, cyanides

1. To treat (a metal surface) with cyanide to produce a hard surface.

2. To treat (an ore) with cyanide to extract gold or silver.

111 (Popup - DEFINITION OF ANODIZING)

anodize (àn´e-dìz´) verb, transitive
anodized, anodizing, anodizes

To coat (a metallic surface) electrolytically with a protective or decorative oxide.

[anod(e) + -ize.]
- an´odiza´tion (-dî-zâ´shen) noun

112 (Popup - DEFINITION OF DIPPING)

dip (dîp) verb
dipped, dipping, dips verb, transitive

1. To plunge briefly into a liquid, as in order to wet, coat, or saturate.

2. To galvanize or plate (metal) by immersion.

verb, intransitive

1. To plunge into water or other liquid and come out quickly.

noun

1. A brief plunge or immersion, especially a quick swim.

2. A liquid into which something is dipped, as for dyeing or disinfecting.

[Middle English dippen, from Old English dyppan.]

113 (Popup - DEFINITION OF ELECTROPLATE)

electroplate (î-lèk´tre-plât´) verb, transitive
electroplated, electroplating, electroplates

To coat or cover with a thin layer of metal by electrodeposition.

114 (Popup - DEFINITION OF GALVANIZING)

galvanize (gàl´ve-nìz´) verb, transitive
galvanized, galvanizing, galvanizes

1. To stimulate or shock with an electric current.

2. To coat (iron or steel) with rust-resistant zinc.
- gal´vaniza´tion (-nî-zâ´shen) noun
- gal´vaniz´er noun

115 (Popup - DEFINITION OF BROACHING)

broach (broch) verb, transitive
broached, broaching, broaches

1. To pierce in order to draw off liquid: broach a keg of beer.

3. To draw off (a liquid) by piercing a hole in a cask or other container.

4. To shape or enlarge (a hole) with a tapered, serrated tool.

noun

1.a. A tapered, serrated tool used to shape or enlarge a hole. b. The hole made by such a tool.

[Middle English brochen, to pierce, probably from broche, pointed weapon or implement, from Old French, from Vulgar Latin *brocca, from Latin broccus, projecting.]
- broach´er noun

116 (Popup - DEFINITION OF EXTRUDING)

extrude (îk-str¡d´) verb
extruded, extruding, extrudes verb, transitive

1. To push or thrust out.

2. To shape (a plastic, for instance) by forcing it through a die.

verb, intransitive
To protrude or project.

[Latin extrúdere : ex-, ex- + trúdere, to thrust.]

117 (Popup - DEFINITION OF FORGING)

Forging, process of shaping iron and other metals by hammering or pressing them after softening them with heat. Forging techniques are useful because the metal can be given the desired form while the process improves the structure of the metal, particularly by refining the grain size. Forged metal is stronger and more ductile than cast metal, exhibiting greater resistance to fatigue and impact.

Hand Forging

Sometimes called smithing, or blacksmithing, hand forging is the simplest form of forging; it is one of the methods by which metal was first worked. The metal is heated to red heat in the fire and

then beaten into shape with hammers on a metal anvil. The forge consists of an open hearth, made of some durable, refractory substance such as firebrick and provided with a number of openings through which air is forced by a bellows or blower fan. Charcoal, coke, and coal are used as fuels.

Machine Forging

The chief difference between hand forging and machine forging is that in machine forging various types of machine-powered hammers or presses are used instead of hand hammers. These machines enable the operator to strike heavy blows with great rapidity and thus to produce forgings of large size and high quality as swiftly as required by modern production lines. Another advantage of machine forging is that the heavier the blows struck during forging, the greater the improvement in the quality of metallic structure.

118 (Popup - DEFINITION OF TURNING)

turning (tûr´nîng) noun

1. a. The shaping of metal or wood on a lathe. b. turnings. Shavings produced in shaping metal on a lathe.

119 (Popup - DEFINITION OF MILLING)

milling (mîl´îng) noun

1. The act or process of grinding, especially grinding grain into flour or meal.

2. The operation of cutting, shaping, finishing, or working products manufactured in a mill.

120 (Popup - DEFINITION OF DRILLING)

drill (drîl) noun

1.a. An implement with cutting edges or a pointed end for boring holes in hard materials, usually by a rotating abrasion or repeated blows; a bit. b. The hand-operated or hand-powered holder for this implement. c. A loud, harsh noise made by or as

if by a powered tool of this kind.

verb
drilled, drilling, drills verb, transitive

1.a. To make a hole in (a hard material) with a drill: a bit for drilling masonry. b. To make (a hole) with or as if with a drill: drills holes in trees with its chisellike bill.

verb, intransitive
1.To make a hole with or as if with a drill.

[Obsolete Dutch dril, from drillen, to bore, from Middle Dutch drillen.]
- drill´er noun

127 (Popup - EASYENTRIE KEY MACHINE AVAILABILITY)
The Easy entrie is distributed in the United States by **Lockmasters** in Nicholasville, Kentucky.

128 (Popup - NEWTON'S LAWS OF MOTION)
Newton's Three Laws of Motion

Newton's first law of motion states that, if the vector sum of the forces acting on an object is zero, then the object will remain at rest or remain moving at constant velocity.

Newton's second law of motion states that a net force on an object will accelerate the object at a rate proportional to the strength of the force and in the same direction as the force.

Newton's third law of motion states that an object experiences a force because it is interacting with some other object, and that the force exerted by object 1 on object 2 must be equal to the force exerted by object 2 on object 1 but in the opposite direction.

129 (Popup - BEST LOCK CORP. V. ILCO UNICAN CORP.)
UNITED STATES COURT OF APPEALS FOR THE FEDERAL CIRCUIT
95-1528

BEST LOCK CORPORATION,

Plaintiff-Appellant,

v.

ILCO UNICAN CORPORATION,

Defendant-Appellee.

Appealed from: U.S. District Court for the Southern District of Indiana (Indianapolis)

Judge McKinney

United States Court of Appeals for the Federal Circuit
95-1528

BEST LOCK CORPORATION,

Plaintiff-Appellant,

v.

ILCO UNICAN CORPORATION,

Defendant-Appellee.

DECIDED: August 29, 1996

Before ARCHER, Chief Judge, NEWMAN and LOURIE, Circuit Judges.

Opinion for the court filed by Circuit Judge LOURIE. Dissenting

opinion filed by Circuit Judge NEWMAN.

LOURIE, Circuit Judge.

Best Lock Corporation appeals from the final decision of the United States District Court for the Southern District of Indiana in which the court held that Best Locks U.S. Design Patent 327,636 was invalid. Best Lock Corp. v. Ilco Unican Corp., 896 F. Supp. 836, 36 USPQ 2d 1527 (S.D. Ind. 1995). Because the court did not clearly err in finding that the claimed design was functional and hence not ornamental, we affirm.

BACKGROUND

This case involves a design patent for a key "blade." A typical key consists of a bow, which allows the user to turn the key in a corresponding lock, and a blade, which is the portion of the key inserted into the lock's keyway. When a key is manufactured, the key blade is "blank," i.e., the blade has not been cut or "bitted" with the combination required to operate the corresponding lock. Although a blank key blade will not operate the lock, the profile of the key blade is manufactured to fit into the corresponding lock's keyway. Subsequently, the blank key blade is cut to match the corresponding lock's combination.

In the replacement key market, a locksmith or a retail store with a key duplicating facility stocks blank key blades with various key profiles. The locksmith or retailer makes a replacement key by first selecting the appropriate blank key blade. This is done by matching the key blade profile with the corresponding lock keyway. Then, the locksmith or retailer cuts the blade of the key blank with the combination required to operate the lock.

Best Lock manufactures and sells locks and keys used to maintain security at industrial, commercial, and institutional facilities. At these facilities, it is often feared that the keys used in their locks may readily be duplicated. Consequently, key and lock manufacturers, including Best Lock, have attempted to restrict unauthorized access to duplicate key blanks by obtaining utility or design patent protection on the keys. By obtaining patent protection, a company hopes to control the market for duplicate key blanks during the life of the patent. 1

Best Lock is the assignee of the two patents that were at issue

before the district court, U.S. Patent 5,136,869 and U.S. Design Patent 327,636. The '869 patent, entitled "High Security Key and Cylinder Lock Assembly," claims an improved key blade and cylinder lock assembly that provides a wider key profile than standard keys and includes other features to deter lock picking. The '636 patent, entitled "Portion of a Key Blade Blank," claims the ornamental design for the operative portion of a key blade blank. In addition to the '636 design patent, Best Lock is the assignee of 33 other design patents on key blade designs. It also is the assignee of 34 design patents directed to keyways designed to mate with the key blades claimed in Best Lock's 34 key blade design patents. The '636 patent is the only design patent at issue on appeal. Figures 1-5 of the '636 design patent are shown below:

Ilco manufactures duplicate and replacement key blanks for existing locks. It sells its replacement key blanks to locksmiths and replacement key retailers. In 1993, Ilco copied the design of a Best Lock key, which had a key blade shaped like the design shown in the '636 patent. It subsequently distributed key blanks with that key blade shape at the annual convention of the Associated Locksmiths of America. In response, Best sued Ilco, alleging, inter alia, infringement of the '636 design patent and the '869 utility patent. Ilco counterclaimed, seeking a declaratory judgment of invalidity and noninfringement of both patents.

After a ten-day bench trial, the district court held that the '869 patent claims were invalid under 35 U.S.C. § 102 because the claims were anticipated by the prior art. Best Lock Corp. v. Ilco Unican Corp., 896 F. Supp. 836, 837, 36 USPQ2d 1527, 1528 (S.D. Ind. 1995). Best Lock has not appealed that holding. The court also held that the '636 design patent was invalid. In particular, the court found that Best Lock's key blades were not "a matter of ornamental concern to the purchaser or the user." Id. at 843, 36 USPQ2d at 1534. The court further found that the design patent was invalid because the shape of the blank key blade was dictated by its function. Id. Best Lock appeals, challenging the district court's decision regarding the '636 patent.

DISCUSSION

Under 35 U.S.C. § 171, a design patent may be granted for a "new, original and ornamental design for an article of manufacture." However, if the design claimed in a design patent is dictated

solely by the function of the article of manufacture, the patent is invalid because the design is not ornamental. See Bonito Boats, Inc. v. Thunder Craft Boats, Inc., 489 U.S. 141, 148, 9 USPQ2d 1847, 1851 (1989) ("To qualify for protection, a design must present an aesthetically pleasing appearance that is not dictated by function alone, and must satisfy the other criteria of patentability."); see also In re Carletti, 328 F.2d 1020, 1022, 140 USPQ 653, 654 (CCPA 1964) ("[I]t has long been settled that when a configuration is the result of functional considerations only, the resulting design is not patentable as an ornamental design for the simple reason that it is not 'ornamental'--was not created for the purpose of ornamenting."). A design is not dictated solely by its function when alternative designs for the article of manufacture are available. See L.A. Gear, Inc. v. Thom McAn Shoe Co., 988 F.2d 1117, 1123, 25 USPQ2d 1913, 1917 (Fed. Cir.), cert. denied, 114 S. Ct. 291 (1993). We review for clear error the district court's determination that the design claimed in the '636 patent is functional. See id. at 1124, 25 USPQ2d at 1917.

On appeal, Best Lock argues that the court erred in holding the '636 design patent invalid as being directed solely to a functional design. As support, it asserts that although a particular key and its corresponding lock must mate to operate the lock, an unlimited number of key blade and corresponding keyway designs are available. Choice of any particular design is arbitrary. Thus, Best Lock maintains that the key blade blank may have any number of different shapes and is therefore not dictated solely by functional concerns.

We disagree. The design shown in the claim of the '636 patent is limited to a blank key blade as shown in Figures 1-5 of the patent. Best Lock did not claim a design for the entire key. See 37 C.F.R. § 1.153 (1995) (The claim of a design patent "shall be in formal terms to the ornamental design for the article . . . as shown, or as shown and described.") (emphasis added). The parties do not dispute that the key blade must be designed as shown in order to perform its intended function--to fit into its corresponding lock's keyway. An attempt to create a key blade with a different design would necessarily fail because no alternative blank key blade would fit the corresponding lock. In fact, Best Lock admitted that no other shaped key blade would fit into the corresponding keyway, and it presented no evidence to the contrary. Therefore, we find no clear error in the court's finding that the claimed key blade design was dictated solely by the key blade's function. Any aesthetic appeal of the key blade

design shown in the '636 patent is the inevitable result of having a shape that is dictated solely by functional concerns.

Further, Best Lock's assertion that a variety of possible shapes of interfaces between keys and locks exists does not compel a different result. Clearly, different interfaces between key blades and corresponding lock keyways can be designed to permit the combination to function as a lock and key set. However, Best Lock's patent does not claim the combination of a lock and corresponding key. Instead, the claim in the '636 design patent is limited to a key blade, which must be designed as shown in the '636 patent in order to perform its intended function.

Moreover, the fact that Best Lock also has a design patent on the keyway that mates with the key blade shown in the '636 patent does not alter our analysis. The existence of a separate patent on the keyway is irrelevant to the construction of the '636 patent claim and to the ultimate determination that the claimed design is dictated solely by function. See Elmer v. ICC Fabricating, Inc., 67 F.3d 1571, 1577, 36 USPQ2d 1417, 1421 (Fed. Cir. 1995) (construing design patent as limited to the article of manufacture "as shown and described" in the patent). The validity of a patent must be evaluated based on what it claims rather than on the totality of the claims of multiple patents.

For the foregoing reasons, the district court's finding that the claimed design is solely governed by functional concerns is not clearly erroneous. Consequently, we affirm its resulting conclusion that the '636 patent is invalid under 35 U.S.C. § 171 for failure to satisfy the statute's ornamentality requirement.

AFFIRMED

NEWMAN, Circuit Judge, dissenting.

I respectfully dissent. The design of this key blade profile meets the statutory criteria of design patent subject matter. The design statute defines this subject matter as follows:

35 U.S.C. §171 Patents for designs

Whoever invents any new, original and ornamental design for an article of manufacture may obtain a patent therefore, subject to the conditions and requirements of this title.

The provisions of this title relating to patents for inventions shall apply to patents for designs, except as otherwise provided.

Whether the design of the D'636 patent is otherwise patentable, for example on the criteria of originality or non-obviousness, was not reached by the district court and is not before us. However, the panel majority has misapplied 35 U.S.C. §171 in holding that the arbitrary design of the key profile is "functional" because it mates with its matching keyway.

The design of the key profile is not removed from access to the design statute because the key fits a matching keyway. That two articles are designed in harmony does not deprive the design of access to the design patent law. The design of the key profile is not determined by the function of the key to fit the lock. In the case at bar there are said to be "thousands" of alternative key blade profiles.

The district court concluded that the design of the D'636 patent was not "a matter of ornamental concern to the purchaser or the user," and thus held that the design was functional. The statute requires that the subject of a design patent be an ornamental design of a useful object. However, "ornamental" does not always mean artistic or pleasing to the eye. The Court of Customs and Patent Appeals early recognized that "the beauty and ornamentation requisite in design patents is not confined to such as may be found in the `aesthetic or fine arts.'" In re Koehring, 37 F.2d 421, 422 (CCPA 1930).

Recognizing that ornamentation is in the eye of the beholder, the courts have sought a more objective standard in the general rule that a design is "ornamental" for purposes of 35 U.S.C. §171 when it is not primarily functional. See In re Carletti, 328 F.2d 1020, 140 USPQ 653 (CCPA 1964) ("To qualify for protection, a design must present an aesthetically pleasing appearance that is not dictated by function alone."). However, the article itself must have a utility in order for its design features to be patentable under 35 U.S.C. §171. See L.A. Gear, Inc. v. Thom McAn Shoe Co., 988 F.2d 1117, 1123, 25 USPQ2d 1913, 1917 (Fed. Cir.) ("A design patent is directed to the appearance of an article of manufacture. An article of manufacture necessarily serves a utilitarian purpose, and the design of a useful article is deemed to be functional when the appearance of the claimed design is `dictated by' the use or purpose of the article."), cert. denied, 510 U.S. 908 (1993).

If the design is dictated by the function performed by the article of manufacture, the design is not patentable. Power Controls Corp. v. Hybrinetics, Inc., 806 F.2d 234, 238, 231 USPQ 774, 777 (Fed. Cir. 1986). See Bonito Boats, Inc. v. Thunder Craft Boats, Inc., 489 U.S. 141, 148, 9 USPQ2d 1847, 1851 (1989) ("To qualify for protection, a design must present an aesthetically pleasing appearance that is not dictated by function alone, and must satisfy the other criteria of patentability."). A design is "not dictated by function alone" when there are alternative designs or configurations available for the article of manufacture, as in the case before us.

The legal principles governing design patents have their foundation in the important decision of Gorham Co. v. White, 81 U.S. (14 Wall.) 511 (1871), wherein the Supreme Court explained:

The appearance may be the result of peculiarity of configuration, or of ornament alone, or of both conjointly, but, in whatever way produced, it is the new thing, or product, which the patent law regards.

81 U.S. at 525. Courts have measured the term "ornamental" by the non-functionality that distinguishes the subject of a design patent from a utility patent, while recognizing that the design of a useful article is not insulated from the utility of the article. A review of patentable designs in general illustrates the mixture of functional and non-functional features embraced in the patented design. See, e.g., Winner Int'l Corp. v. Wolo Mfg. Corp., 905 F.2d 375, 15 USPQ2d 1076 (Fed. Cir. 1990) (design of steering wheel lock); Lee v. Dayton-Hudson Corp., 838 F.2d 1186, 5 USPQ2d 1625 (Fed. Cir. 1988) (design patent for massage device); FMC Corp. v. Hennessy Indus., Inc., 836 F.2d 521, 5 USPQ2d 1272 (Fed. Cir. 1987) (design patent for changer for tubeless tires); Unette Corp. v. Unit Pack Co., 785 F.2d 1026, 228 USPQ 933 (Fed. Cir. 1986) (container for dispensing liquids); In re Igarashi, 228 USPQ 463 (Bd. Pat. App. & Interf. 1985) (tire tread design); Trans-World Mfg. Corp. v. Al Nyman & Sons, Inc., 750 F.2d 1552, 224 USPQ 259 (Fed. Cir. 1984) (design for eyeglass display rack).

An effective design patent law must recognize the distinction between functionality of the article and of the particular design of the article or features thereof. See L.A. Gear, supra, (the sneaker tongue, moustache, delta wing, and side mesh, were useful parts of the sneaker, but the overall design of these features

and the shoe was not dictated by function alone). This interaction of form and function does not remove the design from the statutory scope of the design patent law, or defeat the statutory patentability of a primarily non-functional design - although it is not always easy to draw a bright line between the functionality of an article and its design, as discussed by J.H. Reichman, Design Protection and the New Technologies: The United States Experience in a Transnational Perspective, 19 Balt. L. Rev. 6 (1989), for design patents often appear on quite mundane articles of manufacture. See, e.g., Tone Bros., Inc. v. Sysco Corp., 28 F.3d 1192, 31 USPQ2d 1321 (Fed. Cir. 1994) (bottle for spices); In re Klein, 987 F.2d 1569, 26 USPQ2d 1133 (Fed. Cir. 1993) (roof or siding shingle); KeyStone Retaining Wall Sys., Inc. v. Westrock, Inc., 997 F.2d 1444, 27 USPQ2d 1297 (Fed. Cir. 1993) (concrete block for retaining wall); In re Webb, 916 F.2d 1553, 16 USPQ2d 1433 (Fed. Cir. 1990) (femoral hip stem prosthesis); In re Cho, 813 F.2d 378, 1 USPQ2d 1662 (Fed. Cir. 1987) (bottle cap); Pacific Furniture Mfg. Co. v. Preview Furniture Corp., 800 F.2d 1111, 231 USPQ 67 (Fed. Cir. 1986) (upholstered armchair); Litton Sys., Inc. v. Whirlpool Corp., 728 F.2d 1423, 221 USPQ 97 (Fed. Cir. 1984) (microwave oven); In re Koehring, 37 F.2d 421 (CCPA 1930) (concrete mixing truck).

The design of the key blade profile is primarily non-functional, as the Patent and Trademark Office recognized in granting the patent in suit. The Manual of Patent Examining Procedure defines "design" as follows for purposes of §171:

The design of an object consists of the visual characteristics or aspects displayed by the object. It is the appearance presented by the object which creates a visual impact upon the mind of the observer.

Since a design is manifested in appearance, the subject matter of a design patent application may relate to the configuration or shape of an object, to the surface ornamentation on an object, or both.

Design is inseparable from the object to which it is applied and cannot exist alone merely as a scheme of surface ornamentation. It must be a definite, preconceived thing, capable of reproduction and not merely the chance result of a method.

MPEP §1502 (6th ed. 1995). See also 1 D. Chisum, Patents §1.04[2][a] (1996) ("[A] design rests on appearance created by the configuration of the article, surface ornamentation, or a

combination of configuration and ornamentation.") (footnote omitted).

The parties to this litigation agree that there are myriad possible designs of key profiles. All keys require, of course, mating keyways. In holding that because the key must fit a keyway, the abstract design of the key profile is converted to one solely of function, the court creates an exception to design patent subject matter. An arbitrary design of a useful article is not statutorily excluded from §171 simply because in use it interacts with an article of complementary design. Although precedent is sparse, it is contrary to this holding. In Motorola Inc. v. Alexander Mfg. Co., 786 F. Supp. 808, 21 USPQ2d 1573 (N.D. Iowa 1991), the only United States case on this point of which we are aware, the court considered a design patent for a battery housing intended for use in a portable phone. Since the battery housing had to fit into the phone and a battery charger, the accused infringer argued that this function dictated the design. The court disagreed:

The design of the battery housing was not dictated by the design of the battery charger because the charger did not exist when the housing was designed. The design of the phone was done concurrently with the battery housing. Therefore, the design of the battery housing cannot fairly be said to have been "dictated" by the design of the phone.

Id. at 812, 21 USPQ2d at 1557. This reasoning is equally apt in this case. The design of the key profile was not dictated by the design of the keyway, and indeed the two share the same arbitrary design.

In sum, the fact that the key blade is the mate of a keyway does not convert the arbitrary key profile into a primarily functional design. It is not the design of the key profile that is functional, but the key itself. Thus I must, respectfully, dissent from the ruling of the panel majority that the design of the key blade profile is not patentable because the key blade requires a mating keyway.

Footnotes

1 Key and lock manufacturers also use other methods to restrict access to duplicate key blanks. For example, some manufacturers limit the sale of a particular type of lock and key to a single

customer or particular geographic region, thereby making consumer demand for replacement keys for that particular lock design so small that replacement key manufacturers have no incentive to manufacture duplicate key blanks.

2 As our predecessor court previously held, "a design for an article of manufacture may be embodied in less than all of an article of manufacture. . . ." In re Zahn, 617 F.2d 261, 267, 204 USPQ 988, 994 (CCPA 1980).

As our predecessor court previously held, "a design for an article of manufacture may be embodied in less than all of an article of manufacture. . . ." In re Zahn, 617 F.2d 261, 267, 204 USPQ 988, 994 (CCPA 1980).

132 (Popup - STANDARD KEY CODING SYSTEM)
A, AA, AA1, 1AA..: Symbols for different levels of keying
A1, B1: A change key under the grand master key only
A1A, A1B..: In a system with a large number of master keys, each group may be named following this sequence. A1A, A1B, A1C...A2A, A2B, A2C...This becomes relevant when there are more than 22 master keys in the system. Alternative numbering may then be implemented.

AA1/AA12: This identifier would indicate a double cylinder with each lock keyed differently. AA1 would indicate the outside lock; AA12 the inside cylinder

BM: Block master key
CK: Change key
CMK: Construction master key
EMK: Emergency master key
ENG: Engineer key
GGGMK: Great great great grand master key
GGM: Great grand master key
GGMK: Great grand master key
GGM1: A change key directly under a great grand master key
GM: Grand master key
GMK: Grand master key
HGM: Horizontal group master key

HKP: Housekeeping master key
I: Do not use in standard key coding system to document a keying system
k: Key
KA: Key alike
KA1, KA2...Keyed alike group. This coding indicates that all cylinders in this string are to be operated by the same key or keys.
KA/2, KA/3...Indicates that the quantity of locks is keyed alike in groups.
KBA: Key bitting array
KD: Keyed different
KR: Keyed random, or key retaining, depending upon context.
KWY: Keyway
MK: Master key
NCK: No change key
NKR: Non key retaining
NMK: Not master keyed but part of system. Example: 1AA(NMK). The combination for a NMK lock is part of the progression for the master key system, but is not keyed to any master key level. In contrast, the SKD is simply a lock with a single key combination, such as a pharmacy, weapons or explosives vault or evidence room. The single keyed lock combination is generated as part of a system progression but is not related to any lock within the system. The KBA is utilized to generate the bitting code to prevent key interchange.

O: Do not use in standard key coding system to document a keying system
Q: Do not use in standard key coding system to document a keying system

RM: Row master key
SKD: Single keyed
SMK: Sub master key
TMK: Top level master key
VGM: Vertical group master key
VKC: Visual key control
X: Symbol that designates cross-keyed condition for a particular lock. Do not ever use as a master key symbol

X1X: Symbol that denotes a cross-keyed cylinder with no dedicated change key of its own

133 (Popup - SKCS RULES)

The coding scheme of keys that enable the specification of keying levels adhere to certain rules. Note that the system defines keys and how they are related to each other, but not how many locks are in the system.

General Rules

- coding begins at the lowest keying level;
- key symbols identify the lowest level key that will operate the lock and which is associated with all locks above it. Thus, AB5 is a change key that is part of a keying level that includes AB, A, and the TMK.

· never use the letters I, O, Q for defining keys, because they can be confused with 1 and 0;

· levels of keying can be bypassed or eliminated. For example, a five level system may require that certain change keys be associated directly with a GGGMK, and that there are no master keys under the GGGMK.

Rules for master and change keys

Master Keys

- master key coding always uses pairs of two identical letters (AA, BB);
- grand master keys are always identified by a single letter (never X);
- numbering for master key levels are assigned in a defined sequence or progression: AB, where A = the grand master key and B = master key. The lettering for the master key runs from A, alphabetically;

· the top level master key is noted as TMK, regardless of how many levels there are in the system. Thus, the TMK can be a master key in a two level system, a grand master key in a three level system, etc.;

· the term "sub-master key" is not used until the sixth keying level;

Change Keys

· change key coding always uses letters and numbers such as AA1, BA17;

· change keys are derived from the master key designators to which they are associated. The first letter of all associated keys, from the grand master to the change key, is the same. The second letter of the master key definition remains with the associated change key;

· change keys that are not associated with a master key level directly above it, but with a higher level are coded to that level. For example, in a four level system, a change key directly associated with the GGM would be coded GGM1. Likewise, a change key associated only with the grand master would be coded A1;

· certain locks may be single keyed (SKD), meaning that they are not associated with any other level of keying. They would be identified as SKD-1, SKD-2...In other systems, a change keyed cylinder may be part of the overall keying scheme, but not master keyed. It will then be designated by (NMK) in parenthesis after the key sumbol. Thus, AB28(NMK) would indicate that the lock is set to AB45, but will not be operated by any level of master key.

Rules for levels of keying for change keys

- for two levels of coding, use numbers (first) then letters (1AA, 2AA...) Thus, the key that is identified as 53AA would indicate a two level system, master key AA, change key 53 that is associated with that master key;

- for three or more levels of keying, change key numbers follow letters, thus AA1, AA2...;

136 (Popup - TMK REGISTER CONTENTS)
The TMK register should contain the following information to insure proper system security for all clients and to avoid potential liability upon the part of the locksmith.

- **Register number**
- **Location**
- **File number**
- **Manufacturer**
- **Key section**
- **TMK bitting**
- **Parity pattern or angles**
- **Details and notes, to include the following:**

- **who installed the system**
- **factory derived system**
- **system inherited from another locksmith**
- **inventory information regarding cut and blank keys**
- **system changes**
- **specific authorization instructions**
- **use of OEM blanks required**
- **refer to bitting list**

137 (Popup - MAXIMUM ADJACENT CUT SPECIFICATIONS)

MACS is different for each manufacturer, and specifies the maximum vertical distance between adjacent cuts. Schlage, for example, sets a MACS of 7, which signifies that the difference between cuts cannot exceed this number. Thus, a 9 and a 2 cut can be next to each other, but a 9 and a 1 cut would violate the rule because the difference is 8. MACS prevent steep ramp angles which can lead to erratic operation of keys and improper seating of tumblers within a root that is too narrow.

223 (Popup - BEST REMOVABLE CORE SPECIFICATIONS FOR A2, A3, AND A4 LOCKS)
The **A2** series is the most popular, and has been copied by a number of other manufacturers. There are ten depths (0-9) with a

spacing of .0125", and a MACS of 9. A two-step progression is utilized for master keying, with a cutting angle of 90 degrees. There are no forbidden adjacent bittings.

The **A3** series allows seven depths (0-6), with a spacing of .018", and a MACS of 6. This lock utilizes a single step progression even though the .023" rule is violated, and a 90 degree cutting angle. There are no forbidden adjacent bitting patterns.

The **A4** series allows for six depths (0-5) with a spacing of of .021", and a MACS of 5. Single step progression is utilized for master keying, although it violates the .023" rule. A 90 degree cutting angle is utilized. There are no forbidden adjacent bittings.

241 (Popup - International Association of Investigative Locksmiths, Inc.)
The I.A.I.L. has adopted the following code of ethics for its members.

CODE OF ETHICS

Each member by their acceptance of membership in the International Association of Investigative Locksmiths, Inc. shall subscribe to the following Code of Ethics.

1. To pursue their professional work in the spirit of fairness to their clients, with fidelity to security in conformance with appropriateness, and with high ideals of personal honor.

2. To properly and impartially analyze examine examine material which is entrusted to their custody. To conduct themselves in a dignified manner at all times; to avoid using any improper or questionable methods of soliciting professional work.

4. To refrain from associating themselves with or allowing the use of their name by any enterprise of questionable character, or in any manner countenancing misrepresentation.

5. To cooperate with other investigative locksmiths through the

interchange of general information and experience.

6. To cooperate with local law enforcement officials and insurance investigators in all matters relating to the cases that they are working on, and to diligently pursue the education of the consumer in relation to their security.

7. To encourage and promote loyalty for the investigative locksmith profession and interest themselves in public welfare, always ready to apply their special knowledge, skill and training to enhance the security of the public.

8. To consistently abide by all applicable licensing and business regulations.

Adopted: October 7, 1999 by Board Resolution, International Association of Investigative Locksmiths, Inc.

242 (Popup - NOTES TO RULE 702)
HISTORY: (Jan. 2, 1975, P.L. 93-595, § 1, 88 Stat. 1937.)

Notes of Advisory Committee on Rules.

An intelligent evaluation of facts is often difficult or impossible without the application of some scientific, technical, or other specialized knowledge. The most common source of this knowledge is the expert witness, although there are other techniques for supplying it.

Most of the literature assumes that experts testify only in the form of opinions. The assumption is logically unfounded. The rule accordingly recognizes that an expert on the stand may give a dissertation or exposition of scientific or other principles relevant to the case, leaving the trier of fact to apply them to the facts. Since much of the criticism of expert testimony has centered upon the hypothetical question, it seems wise to recognize that opinions are not indispensable and to encourage the use of expert testimony in non-opinion form when counsel believes the trier can itself draw the requisite inference. The use of opinions is not abolished by the rule, however. It will continue to be permissible for the experts to take the further step of suggesting the inference which should be drawn from applying the specialized knowledge to the facts. See Rules 703 to 705 .

Whether the situation is a proper one for the use of expert

testimony is to be determined on the basis of assisting the trier. "There is no more certain test for determining when experts may be used than the common sense inquiry whether the untrained layman would be qualified to determine intelligently and to the best possible degree the particular issue without enlightenment from those having a specialized understanding of the subject involved in the dispute." Ladd, Expert Testimony, 5 Vand.L.Rev. 414, 418 (1952). When opinions are excluded, it is because they are unhelpful and therefore superfluous and a waste of time. 7 Wigmore § 1918.

The rule is broadly phrased. The fields of knowledge which may be drawn upon are not limited merely to the "scientific" and "technical" but extend to all "specialized" knowledge. Similarly, the expert is viewed, not in a narrow sense, but as a person qualified by "knowledge, skill, experience, training or education." Thus within the scope of the rule are not only experts in the strictest sense of the word, e.g., physicians, physicists, and architects, but also the large group sometimes called "skilled" witnesses, such as bankers or landowners testifying to land values.

Preliminary draft of proposed amendments.

The Committee on Rules of Practice and Procedure of the Judicial Conference of the United States proposed the following amendment of Rule 702, dated August 15, 1991:

Testimony providing scientific, technical, or other specialized information, in the form of an opinion or otherwise, may be permitted only if (1) the information is reasonably reliable and will substantially assist the trier of fact to understand the evidence or to determine a fact in issue and (2) the witness is qualified as an expert by knowledge, skill, experience, training, or education to provide such testimony. Except with leave of court for good cause shown, the witness shall not testify on direct examination in any civil action to any opinion or inference, or reason or basis therefore, that has not been seasonably disclosed as required by Rules 26(a)(2) and 26(e)(1) of the Federal Rules of Civil Procedure.

Committee notes.

This revision is intended to limit the use, but increase the utility and reliability, of party-initiated opinion testimony bearing on scientific and technical issues.

The use of such testimony has greatly increased since enactment of the Federal Rules of Evidence. This result was intended by the drafters of the rule, who were responding to concerns that the restraints previously imposed on expert testimony were artificial and an impediment to the illumination of technical issues in dispute. See, e.g., McCormick on Evidence , § 203(3d ed., 1984). While much expert testimony now presented is illuminating and useful, much is not. Virtually all is expensive, if not to the proponent then to adversaries. Particularly in civil litigation with high financial stakes, large expenditures for marginally useful expert testimony has become commonplace. Procurement of expert testimony is occasionally used as a trial technique to wear down adversaries. In short, while testimony from experts may be desirable if not crucial in many cases, excesses cannot be doubted and should be curtailed.

While concern for the quality and even integrity of hired testimony is not new, Winans v. New York & Erie R.R., 62 U.S. 88, 101 (1858); Hand, Historical and Practical Considerations Regarding Expert Testimony, 15 Harv. L. Rev. 40 (1901), the hazards to the judicial process have increased as more technical evidence is presented:

When the evidence relates to highly technical matters and each side has shopped for experts favorable to its position, it is naive to expect the jury to be capable of assessing the validity of dramatically opposed testimony.

3J. WEINSTEIN & M. BERGER, WEINSTEIN'S EVIDENCE, § 706[01] at 706-07(1985).

While the admissibility of such evidence is, and remains, subject to the general principles of Rule 403 , the revision requires that expert testimony be "reasonably reliable" and "substantially assist" the fact-finder. The rule does not mandate a return to the strictures of Frye v. United States, 293 F.2d 1013 (D.C. Cir., 1923) (requiring general acceptance of the scientific premises on which the testimony is based). However, the court is called upon to reject testimony that is based upon premises lacking any significant support and acceptance within the scientific community, or that otherwise would be only marginally helpful to the fact-finder. In civil cases the court is authorized and expected under revised Rule 26(c)(4) of the Federal Rules of Civil Procedure to impose in advance of trial appropriate restrictions on the use of expert testimony. In

exercising this responsibility, the court should not only consider the potential admissibility of the testimony under Rule 702 but also weigh the need and utility of the testimony against the time and expense involved.

In deciding whether the opinion evidence is reasonably reliable and will substantially assist the trier of fact, as well as in deciding whether the proposed witness has sufficient expertise to express such opinions, the court, as under present Rule 702, is governed by Rule 104(a) .

The rule is also revised to complement changes in the Federal Rules of Civil Procedure requiring pretrial disclosure of the expert testimony to be presented at trial. The rule precludes the offering on direct examination in civil actions of expert opinions, or the reasons or bases for opinions, that have not been adequately and timely disclosed in advance of trial. It has not been unusual for the testimony given at trial by an expert to vary substantially from that provided under former Fed. R. Civ. P. 26(b)(4)(A)(i) or at a deposition of the expert. At a minimum, any significant changes in an expert's expected testimony should be disclosed before trial, and this revision of Rule 702 provides an appropriate incentive for such disclosure in addition to those contained in the Rules of Civil Procedure.

Additions or other changes to an expert's opinions must, under Fed. R. Civ. P. 26(e)(1), be disclosed no later than the time the proponent is required to disclose its witnesses and exhibits that are to be used at trial. Unless the court has specified another time, these revisions must be disclosed at least 30 days before trial.

Of course, a witness should not be required to testify contrary to the person's oath or affirmation. If the witness is unable, consistent with the oath or affirmation, to testify in a manner consistent with the earlier disclosure, then--unless the court grants leave to deviate from the earlier testimony--the witness should not testify.

By its terms the new sentence applies only in civil cases. The consequences of the failure to make disclosures of expert testimony which may be required under new Fed. R. Crim. P. 16(a)(1)(E) and 16(b)(1)(C) will be determined in accordance with the principles that govern enforcement of the requirements of Fed. R. Crim. P. 16.

243 (Popup - NOTES ON FEDERAL RULE 703)
HISTORY: (Jan. 2, 1975, P.L. 93-595, § 1, 88 Stat. 1937; Mar. 2, 1987, eff. Oct. 1, 1987.)

Notes of Advisory Committee on Rules.

Facts or data upon which expert opinions are based may, under the rule, be derived from three possible sources. The first is the firsthand observation of the witness, with opinions based thereon traditionally allowed. A treating physician affords an example. Rheingold, The Basis of Medical Testimony, 15 Vand.L.Rev. 473, 489 (1962). Whether he must first relate his observations is treated in Rule 705 . The second source, presentation at the trial, also reflects existing practice. The technique may be the familiar hypothetical question or having the expert attend the trial and hear the testimony establishing the facts. Problems of determining what testimony the expert relied upon, when the latter technique is employed and the testimony is in conflict, may be resolved by resort to Rule 705 . The third source contemplated by the rule consists of presentation of data to the expert outside of court and other than by his own perception. In this respect the rule is designed to broaden the basis for expert opinions beyond that current in many jurisdictions and to bring the judicial practice into line with the practice of the experts themselves when not in court. Thus a physician in his own practice bases his diagnosis on information from numerous sources and of considerable variety, including statements by patients and relatives, reports and opinions from nurses, technicians and other doctors, hospital records, and X rays. Most of them are admissible in evidence, but only with the expenditure of substantial time in producing and examining various authenticating witnesses. The physician makes life-and-death decisions in reliance upon them. His validation, expertly performed and subject to cross-examination, ought to suffice for judicial purposes. Rheingold, supra, at 531; McCormick § 15. A similar provision is California Evidence Code § 801(b).

The rule also offers a more satisfactory basis for ruling upon the admissibility of public opinion poll evidence. Attention is directed to the validity of the techniques employed rather than to relatively fruitless inquiries whether hearsay is involved. See Judge Feinberg's careful analysis in Zippo Mfg. Co. v. Rogers Imports, Inc., 216 F.Supp. 670 (S.D.N.Y. 1963) See also Blum et al, The Art of Opinion Research: A Lawyer's Appraisal of an Emerging Service, 24 U.Chi.L.Rev. 1 (1956); Bonynge, Trademark Surveys and Techniques and Their Use in Litigation, 48 A.B.A.J.

329 (1962); Zeisel, The Uniqueness of Survey Evidence, 45 Cornell L.Q. 322 (1960); Annot., 76 A.L.R.2d 919.

If it be feared that enlargement of permissible data may tend to break down the rules of exclusion unduly, notice should be taken that the rule requires that the facts or data "be of a type reasonably relied upon by experts in the particular field." The language would not warrant admitting in evidence the opinion of an "accidentologist" as to the point of impact in an automobile collision based on statements of bystanders, since this requirement is not satisfied. See Comment, Cal.Law Rev.Comm'n, Recommendation Proposing an Evidence Code 148-150 (1965).

Notes of Advisory Committee on 1987 amendments to Rules.

The amendment is technical. No substantive change is intended.

244 (Popup - NOTES ON RULE 704)
HISTORY: (Jan. 2, 1975, P.L. 93-595, § 1, 88 Stat. 1937; Oct. 12, 1984, P.L. 98-473, Title II, Ch IV, § 406, 98 Stat. 2067.)

AMENDMENTS:

1984. Act Oct. 12, 1984 substituted this rule for one which read: "Testimony in the form of an opinion or inference otherwise admissible is not objectionable because it embraces an ultimate issue to be decided by the trier of fact."

Notes of Advisory Committee on Rules.

The basic approach to opinions, lay and expert, in these rules is to admit them when helpful to the trier of fact. In order to render this approach fully effective and to allay any doubt on the subject, the so-called "ultimate issue" rule is specifically abolished by the instant rule.

The older cases often contained strictures against allowing witnesses to express opinions upon ultimate issues, as a particular aspect of the rule against opinions. The rule was unduly restrictive, difficult of application, and generally served only to deprive the trier of fact of useful information. 7 Wigmore §§ 1920, 1921; McCormick § 12. The basis usually assigned for the rule, to prevent the witness from "usurping the province of the jury," is aptly characterized as "empty rhetoric." 7 Wigmore § 1920, p. 17. Efforts to meet the felt needs of particular situations led to odd verbal circumlocutions which

were said not to violate the rule. Thus a witness could express his estimate of the criminal responsibility of an accused in terms of sanity or insanity, but not in terms of ability to tell right from wrong or other more modern standard. And in cases of medical causation, witnesses were sometimes required to couch their opinions in cautious phrases of "might or could," rather than "did," though the result was to deprive many opinions of the positiveness to which they were entitled, accompanied by the hazard of a ruling of insufficiency to support a verdict. In other instances the rule was simply disregarded, and, as concessions to need, opinions were allowed upon such matters as intoxication, speed, handwriting, and value, although more precise coincidence with an ultimate issue would scarcely be possible.

Many modern decisions illustrate the trend to abandon the rule completely. People v. Wilson, 25 Cal.2d 341, 153 P.2d 720 (1944), whether abortion necessary to save life of patient; Clifford-Jacobs Forging Co. v. Industrial Comm., 19 Ill.2d 236, 166 N.E.2d 582 (1960), medical causation; Dowling v. L. H. Shattuck, Inc., 91 N.H. 234, 17 A.2d 529 (1941), proper method of shoring ditch; Schweiger v. Solbeck, 191 Or. 454, 230 P.2d 195 (1951), cause of landslide. In each instance the opinion was allowed.

The abolition of the ultimate issue rule does not lower the bars so as to admit all opinions. Under Rules 701 and 702 , opinions must be helpful to the trier of fact, and Rule 403 provides for exclusion of evidence which wastes time. These provisions afford ample assurances against the admission of opinions which would merely tell the jury what result to reach, somewhat in the manner of the oath-helpers of an earlier day. They also stand ready to exclude opinions phrased in terms of inadequately explored legal criteria. Thus the question, "Did T have capacity to make a will?" would be excluded, while the question, "Did T have sufficient mental capacity to know the nature and extent of his property and the natural objects of his bounty and to formulate a rational scheme of distribution?" would be allowed. McCormick § 12.

For similar provisions see Uniform Rule 56(4); California Evidence Code § 805; Kansas Code of Civil Procedures § 60-456(d); New Jersey Evidence Rule 56(3).

245 (Popup - NOTES ON RULE 705)
HISTORY: (Jan. 2, 1975, P.L. 93-595, § 1, 88 Stat. 1938; Mar. 2,

1987, eff. Oct. 1, 1987.) (Amended Dec. 1, 1993.)

Notes of Advisory Committee on Rules.

The hypothetical question has been the target of a great deal of criticism as encouraging partisan bias, affording an opportunity for summing up in the middle of the case, and as complex and time consuming. Ladd, Expert Testimony, 5 Vand.L.Rev. 414, 426-427 (1952). While the rule allows counsel to make disclosure of the underlying facts or data as a preliminary to the giving of an expert opinion, if he chooses, the instances in which he is required to do so are reduced. This is true whether the expert bases his opinion on data furnished him at secondhand or observed by him at firsthand.

The elimination of the requirement of preliminary disclosure at the trial of underlying facts or data has a long background of support. In 1937 the Commissioners on Uniform State Laws incorporated a provision to this effect in the Model Expert Testimony Act, which furnished the basis for Uniform Rules 57 and 58. Rule 4515, N.Y. CPLR (McKinney 1963), provides: "

Unless the court orders otherwise, questions calling for the opinion of an expert witness need not be hypothetical in form, and the witness may state his opinion and reasons without first specifying the data upon which it is based. Upon cross-examination, he may be required to specify the data . . .,".

See also California Evidence Code § 802; Kansas Code of Civil Procedure §§ 60-456, 60-457; New Jersey Evidence Rules 57, 58.

If the objection is made that leaving it to the cross-examiner to bring out the supporting data is essentially unfair, the answer is that he is under no compulsion to bring out any facts or data except those unfavorable to the opinion. The answer assumes that the cross-examiner has the advance knowledge which is essential for effective cross-examination. This advance knowledge has been afforded, though imperfectly, by the traditional foundation requirement. Rule 26(b)(4) of the Rules of Civil Procedure, as revised, provides for substantial discovery in this area, obviating in large measure the obstacles which have been raised in some instances to discovery of findings, underlying data, and even the identity of the experts. Friedenthal, Discovery and Use of an Adverse Party's Expert Information, 14 Stan.L.Rev. 455 (1962).

These safeguards are reinforced by the discretionary power of the judge to require preliminary disclosure in any event.

Notes of Advisory Committee on 1987 amendments to Rules.

The amendment is technical. No substantive change is intended.

Notes of Advisory Committee on 1993 amendments to Rules.

This rule, which relates to the manner of presenting testimony at trial, is revised to avoid an arguable conflict with revised Rules 26(a)(2)(B) and 26(a)(1) of the Federal Rules of Civil Procedure or with revised Rule 16 of the Federal Rules of Criminal Procedure, which require disclosure in advance of trial of the basis and reasons for an expert's opinions.

If a serious question is raised under Rule 702 or 703 as to the admissibility of expert testimony, disclosure of the underlying facts or data on which opinions are based may, of course, be needed by the court before deciding whether, and to what extent, the person should be allowed to testify. This rule does not preclude such an inquiry.

246 (Popup - HANS MEJLSHEDE REPORT)

On May 23, 1998, our locksmith Ole Mejlshede collected a cylinder for a door lock at above mentioned address. The cylinder and the key are shown on photo 454.01. In a larger scale the key is shown on photo 454 two and the face of the cylinder on photo 454 three. The cylinder is a Ruko type 5201 as is used for Ruko's program of rim locks. It is an older type, the age is estimated to 15-20 years. The key profile is Ruko's universal keyway, where there is no key control. The key is not one of the originals. It is a copy made on an aluminum blank.

Most locksmiths consider this type of cylinder as easy to pick, but all picking tools, when used, leave marks on the inner part of the cylinder, marks that are easy to trace in a microscope. In this cylinder there is an enormous amount of marks. In photo 454.04, the two first pins are shown from the tip, and on 454.05 from the side. These marks have NOT been made with a picking tool, but most likely with a smaller screwdriver. If the marks have been made in an attempt to open the lock, then the individual who made them hasn't got the slightest idea of lock

picking.

However, this doesn't conclude the finding. Photo 454.06 shows the two last pins of the cylinder. On these pins, there are clear marks from a pick gun, but the marks are not new. They are more likely 1-2 years old. This is seen on the oxidation of the marks, and of the wear that the key has produced over the marks.

In this case, we haven't dismounted the cylinder ourselves. For that reason, we can't be certain that the lock has functioned correctly, at the time of entry. Upon collection of the cylinder, we noticed a letter slot in the door. Coupled with the fact that the lock has a thumb turn on the inside makes it possible to use a "jimmy" to open the lock through the letter slot. This method of opening the door is virtually unknown to burglars in Denmark, so the probability it has been used is very little. However, we can't exclude it, and it is often not possible to trace.

Summary: The cylinder has some bruises, but it is very unlikely that it has been opened with any picking tool within the last year. The cylinder has been picked prior to this. The lock could have been opened with a "jimmy", but since the method is almost unknown, the probability for this is little.

Note by Author: this case suggests the probability that a simulated burglary may have been the cause of the marks on the first two pins. This is a common practice with lay persons who are not familar with lock picking procedures, and attempt to create the impressin of a burglary.

255 (Popup - STUDY BY W.G. PLUMTREE REGARDING THE ANALYSIS OF PIN TUMBLER LOCKS)

In 1975, **Plumtree** published the results of extensive **tests** that he performed on disc and pin tumbler cylinders in an effort to identify pick marks. He tested 300 pin tumbler cylinders, 225 disc tumbler cylindrs, 20 pin tumbler plugs, and 15 disc tumbler plugs. The lock components were all examined with a variable power microscope (X8 to X30). The following results were reported by Plumtree:

"Marks produced by a key (wear mark(s) on the tumblers of a cylinder appear as a single large wear area on the face of each tumbler. The wear marks are more pronounced on the pins near the front of the lock cylinder and become less pronounced toward the rear."

"There are no obvious striated or impression marks on the tumblers of cylinders that have only been operated by the proper key. Tumblers from a cylinder that have been manipulated with a hook or rake pick have striated marks on each tumbler. Tumblers that have been manipulated with a bounce pick have impression marks."

Source: **"The Examination of Disc and Pin Tumbler Locks for Tool Marks Made by Lock Picks,"** W.G. Plumtree, M.S. published in Forensic Sciences, American Acadmey of Forensic Sciences, Vol. 20, No.4, 10/1975, pp. 656-667.

256 (Popup - NOTE REGARDING SPRINGS)

Spring condition was varried to determine if erroneous readings would be obtained due to the position of each disc within its chamber.

338 (Popup - POTENTIAL SECURITY ISSUE WITH MEDECO BIAXIAL LOCK)

There is a potential problem with the design of the Biaxial regarding the actual numbers of differs that may be available, and the ability to impression the lock. It appears from preliminary tests that a key having a specific combination may very well open the lock with a different keying combination, much like cross-keying. In fact, a key with a depth code and fore or aft pin location may also open a different depth and fore or aft code. This results from the design of the lock and the lifting of pins at different points on their bitting ramps. The result is the reduction in security of the lock. Medeco should be consulted for the actual number of differs available within the Biaxial system, because it is believed that the published number is far greater than the actual number of useable combinations.

344 (Popup - EXTRAPOLATION OF THE TOP LEVEL MASTER KEY)

The author has chosen to define the derivation of the bitting values of the TMK with the term **"extrapolation."** This denotes a process of decoding the individual pin stacks for master pins by using the change key as the standard for comparison.

345 (Popup - LOWER PINS)

The author uses the term "lower pin" to denote all pins in the pin stack, including bottom pin and master pin.

346 (Popup - VISUAL KEY CONTROL DEFINITION)

Visual key control is a specification that all keys and the visible front portion of any cylinder be identified with standard keying symbols.

347 (Popup - TPP SYSTEM)

Strictly speaking, all positions must be progressed in a total position progression system. That is why the distinction is drawn between TPP and PPP systems in this text.

348 (Popup - MEDECO CAM LOCK)

Medeco utilizes what can be called virtual master pins in the cam lock, but they still can be decoded.

349 (Popup - ASSA SIDEBAR CODING NOMENCLATURE)

Assa indicates left and right contact points with finger pins by writing the depth values as two digit numbers for each position.

350 (Popup - ASSA NOMENCLATURE FOR V10 SIDEBAR CODING)

The author utilizes the _underscore to indicate the inactive side milling for each position. Thus, _5_5 would denote that a Right contact finger pin with a depth of 5 was used in the first and second position.

351 (Popup - LEGALLY PROTECTED BLANKS)

The reader is cautioned that the use of profile milling machines for the duplication of legally protected blanks may constitute a federal offense. The reader should make their own determination as to their authority to replicate such blanks or secondary protective mechanisms. The infringement of patented keyways is not recommended, encouraged, or suggested by the author. Each agency must make their own assessment of the necessity and approval for such action.

403 (Popup - 18 USC 2332a WEAPONS OF MASS DESTRUCTION and DESTRUCTIVE DEVICES)

The term "weapon of mass destruction" as extracted from 18 USC § 2332a and § 921 means

Any destructive device as defined (§ 921) below:

a. The term "destructive device" which means:

(1) any explosive, incendiary, or poison gas;

(2) bomb;

(3) grenade;

(4) rocket having a propellant charge of more than four ounces;

(5) missile having an explosive or incendiary charge of more than one-quarter

ounce;

(6) mine; or

(7) similar devices as described in section 921.

(8) The term "destructive device" shall not include:

(a) Any device which is neither designed or redesigned for use as a weapon;

(b) Any device, although originally designed for use as a weapon, which is redesigned for use as a signaling, pyrotechnic, line throwing, safety or similar device;

(c) Surplus ordnance sold, loaned, or given by the Secretary of

the Army pursuant to the provisions of section 4684 (2), 4685, or 4686 of title 10; or

(d) Any other device which Secretary of the Treasury finds not likely to be used as a weapon is an antique, or is rifle which the owner intends to use solely for sporting, recreational or cultural purposes.

b. Any type of weapon (other than a shotgun or a shotgun shell which the Secretary [Secretary of Treasury or his delegate] finds is generally recog-nized as particularly suitable for sporting purposes) by whatever name known which will, or which may be readily converted to, expel a projectile by the action of an explosive or other propellant, and which has any barrel with a bore of more than one-half inch in diameter; and

c. Any combination of parts either designed or intended for use in converting any device into any destructive device described in paragraphs a and b, above from which a destructive device may be readily assembled.

d. Any weapon that is designed or intended to cause death or serious bodily injury through the release, dissemination or impact of toxic or poisonous chemicals or their precursors;

e. Any weapon involving a disease or organism or;

f. Any weapon that is designed to release radiation or radioactivity at a level dangerous to human life.

404 (Popup - 18 USC 831 EXPLOSIVES AND OTHER DANGEROUS ARTICLES)
§ 831. Prohibited transactions involving nuclear materials

(a) Whoever, if one of the circumstances described in subsection (c) of this

section occurs—

(1) without lawful authority, intentionally receives, possesses, uses, transfers, alters, disposes of, or disperses any nuclear material or nuclear byproduct material and—

(A) thereby knowingly causes the death of or serious bodily

injury to any person or substantial damage to property or to the environ-ment; or

(B) circumstances exist, or have been represented to the defendant to exist, that are likely to cause the death or serious bodily injury to any person, or substantial damage to property or to the envi-ronment;

(2) with intent to deprive another of nuclear material or nuclear byproduct material knowingly—

(A) takes and carries away nuclear material or nuclear byproduct material of another without authority;

(B) makes an unauthorized use, disposition, or transfer, of nuclear material or nuclear byproduct material belonging to another; or

(C) uses fraud and thereby obtains nuclear material or nuclear byproduct material belonging to another;

(3) knowingly—

(A) uses force; or

(B) threatens or places another in fear that any person other than the actor will imminently be subject to bodily injury; and thereby takes nuclear material or nuclear byproduct material belonging to another from the person or presence of any other;

(4) intentionally intimidates any person and thereby obtains nuclear material or nuclear byproduct material belonging to another;

(5) with intent to compel any person, international organization, or gov-ernmental entity to do or refrain from doing any act knowingly threat-ens to engage in conduct described in paragraph (2) (A) or (3) of this subsection;

(6) knowingly threatens to use nuclear material or nuclear byproduct material to cause death or serious bodily injury to an person or sub-stantial damage to property or to the environment under circum-stances in which the threat may reasonably be understood as an expression of serious purposes:

(7) attempts to commit an offense under paragraph (1), (2), (3),

or (4) of this subsection; or

(8) is a party to a conspiracy of two or more persons to commit an offense under paragraph (1), (2), (3), or (4) of this subsection, if any of the parties intentionally engages in any conduct in furtherance of such offense;

Sub paragraphs (b) and (c) omitted.
(d) The Attorney General may request assistance from the Secretary of Defense under chapter 18 of title 10 in the enforcement of this section and the Secretary of Defense may provide such assistance in accordance with chapter 18 of title 10, except that the Secretary of Defense may pro-vide such assistance through any Department of Defense personnel.

(e)

(1) The attorney General may also request assistance from the Secretary of Defense under this subsection in the enforcement of this section. Notwithstanding section 1385 of this title, the Secretary of Defense may, in accordance with other applicable law, provide such assistance to the Attorney General if—

(A) an emergency situation exists (as jointly determined by the Attor-ney General and the Secretary of Defense in their discretion); and

(B) the provision of such assistance will not adversely affect the mili-tary preparedness of the United States (as determined by the Secretary of Defense in such Secretary's discretion).

(2) As used in this subsection, the term "emergency situation" means a circumstance—

(A) that poses a serious threat to the interests of the United States; and

(B) in which—

(i) enforcement of the law would be seriously impaired if the assistance were not provided; and

(ii) civilian law enforcement personnel are not capable of enforc-ing law.

(3) Assistance under this section may include—

(A) use of personnel of the Department of Defense to arrest persons and conduct searches and seizures with respect to violations of this section; and

(B) such other activity as is incidental to the enforcement of this sec-tion, or to the protection of persons or property from conduct that violates this section.

(4) The Secretary of Defense may require reimbursement as a condition of assistance under this section.

(5) The Attorney General may delegate the Attorney General’s function under this subsection only to a Deputy, Associate, or Assistant Attor-ney General.

(f) As used in this section—

(1) the term “nuclear material” means material containing any—

(A) plutonium;

(B) uranium not in the form of ore or ore residue that contains the mixture of isotopes as occurring in nature;

(C) enriched uranium, defined as uranium that contains the isotope 233 or 235 or both in such amount that the abundance ratio of the sum of those isotopes to the isotope 238 is greater than the ratio of the isotope 235 to the isotope 238 occurring in nature; or

(D) uranium 233;

(2) the term “nuclear byproduct material” means any material containing any radioactive isotope created through an irradiation process in the operation of a nuclear reactor or accelerator;

(3) the term “international organization” means a public international organization designated as such pursuant to section 1 of the International Organizations Immunities Act (22 U.S.C. 288) or a public orga-nization created pursuant to treaty or other agreement under international law as an instrument through or by which two or moreforeign governments engage in some aspect of their conduct of international affairs;

(4) the term “serious bodily injury” means bodily injury which

involves-

(A) a substantial risk of death;

(B) extreme physical pain:

(C) protracted and obvious disfigurement; or

(D) protracted loss or impairment of the function of a bodily member, organ, or mental faculty;

(5) the term “bodily injury” means

(A) a cut, abrasion, bruise, burn, or disfigurement;

(B) physical pain;

(C) illness;

(D) impairment of a function of a bodily member, organ, or mental faculty, or

(E) any other injury to the body, no matter how temporary;

(6) the term “national of the United States” has the same meaning as in section 101(a)(22) of the Immigration and Nationality Act (8 U.S.C. 1101(a)(22)); and

(7) the term “United States corporation or other legal entity” means any corporation or other entity organized under the laws of the United States or any State or Commonwealth, territory, possession, or district of the United States.

433 (Popup - REVIEW OF SOFT DRILL)
Don’t Call Me an AutoDialer!!

I’ve seen a lot of clever safe opening tools in my time, but must say none have grabbed my attention as much as the new SoftDrill lock profiler. The SoftDrill is capable of opening the most common combination safe locks with no damage...often in under 30 minutes! This is a pretty big claim--and before I was convinced I had to test it myself to believe it.

First a little background on the SoftDrill profiler. This clever device was developed by the Mas-Hamilton Group (the same folks who make the X-07 and Auditcon safe locks), starting from scratch about a year and a half ago. A team of engineers was dedicated solely to this project with the goal of developing a machine that could quickly and reliably "manipulate" common mechanical locks. They studied locks and the methods used by safe technicians to open them. The engineering team then took this information and strove to build a device that could open locks with little or no skill on the operator’s part.

The coined term "SoftDrill" is a play on words of sort. The device is "software" driven, and performs a task normally reserved for a drill. In addition the words imply a "soft" safe opening. Although the SoftDrill performs a function very similar to classic manipulation, the manufacturer refers to it as a lock "profiler". The implication is that even manipulation resistant locks are still capable of being profiled--that is, of revealing their secrets through careful analysis!

SoftDrill comes neatly fit into a briefcase-size carrying case, and tips the scales at 23 pounds. It consists of a control unit, magnetic base, stepper motor, various-size pulleys, connecting cables, and other support hardware. A user supplied laptop computer (loaded with the provided software) is also needed to run SoftDrill. When setup it is similar in appearance to an autodialer. Looks can be very deceiving!

LAPTOP REQUIREMENTS: You will need your own laptop to run SoftDrill. Many of us are already equipped with laptops to run code and business programs. If you don't have one yet this is one more reason to go shopping. Virtually any new laptop has what it takes to run SoftDrill. To check out your old clunker for compatibility, here are the minimum requirements:

Computer: IBM-compatible laptop
Processor: Pentium
Drives: CD-ROM
Hard Drive: 5MB free space
PCMCIA Card Slot: One-Type II
RAM: 16 MB
Monitor: VGA
O/S: Microsoft Windows 95 or 98 (no, you can't skate by with 3.1!)
To prepare your laptop to operate SoftDrill you will need to do two basic things: Load the SoftDrill program onto your hard drive, and install the DAC card into your laptop's PCMCIA slot. (These items and installation instructions are included with SoftDrill.) Installation is straightforward, and after the setup is done you don't have to fuss with it anymore.

SOFTDRILL SETUP: Once your laptop is prepared you are ready to setup the SoftDrill hardware on your safe. Remember that this device does not open safes--it opens safe locks. The assumed circumstance for using SoftDrill is when there is a lock in working order--but with a lost combination. Currently two common locks are supported: The S&G 6730 and the LaGard 3330 (both are extremely common worldwide). Use the appearance of the dial and ring, as well as contact points and wheel counting to determine if you are dealing with one of the supported locks. Future software upgrades will be made available to open a wider range of locks.

Next, examine the surface of the safe immediately surrounding the dial and ring. Note the presence or absence of any escutcheon, handle, hinge, or other object that disrupts the surface. Check to see if the surface itself will attract a magnet (the SoftDrill hardware is mounted by magnets). The geography of the safe in the area of the dial dictates where to attach the magnetic base and how to configure it. A base extension (included) helps you position the magnets outside most non-magnetic escutcheons. The base itself is asymmetrical and reversible--permitting a wide range of possible mounting configurations.

Once the configuration and position of the base is determined you can mount the stepper motor to the base in advance of mounting the base on the safe. The stepper motor slides onto a pivot stud that extends outwards from the mounting base, and is held in place by a series of large, knurled locking nuts. The belt tension spring that extends from the stepper motor assembly is connected to a separate stud on the mounting base. You are now ready to mount the base!

The two "locator studs" on the base are butted against the dial ring to assure the proper relation between the base and dial. Now carefully bring the base near the safe and let the strong magnets do their work. Once in place the base will be difficult (if not impossible) to reposition without entirely removing it and starting over. That's how powerful the three mounting magnets are! Learning this step may cause a few pinched fingers, but in no time you'll be positioning the base quickly and painlessly.

The next step is to determine which of the SoftDrill's six aluminum dial pulleys fits your safe's dial. This selection covers just about every dial you are likely to encounter with the supported locks. Push the correct size pulley onto the dial and secure it with the provided set screws. Next, loop the timing belt over the pulley at the end of the stepper motor, then over the dial pulley. (The motor can be easily pushed towards the dial to help you accomplish this, courtesy of the belt tension spring.) Now adjust the knurled locking nuts so that the dial pulley and motor pulley are well-aligned. This adjustment will keep the timing belt "on track".

We are now ready to make the various cable connections. These are surprisingly straightforward--there is virtually no chance of plugging something into "the wrong place". Great for those of us with "computer connection phobia"!

Make sure the rocker switch in the briefcase is in the "off" position, then plug the power cord into a 110V AC outlet.
Plug the serial port cable into the back of your laptop, and one end of the PCMCIA cable into the DAC card you installed. Boot the laptop.
Plug the other end of your serial port cable into the appropriate connector in the briefcase.
Plug the other end of the PCMCIA cable into the briefcase.
Connect the cable that comes from the stepper motor to the stepper motor/encoder connector in the briefcase.

Mount the magnet-base accelerometer (think of it as a microphone) near the safe dial, and plug its cable into the BNC connector in the briefcase.
Set the safe dial with "0" under the opening index.
Turn the rocker switch in the briefcase "ON" to power the SoftDrill.
NOTE: Believe me folks--this entire setup procedure flies by once you've done it a few times. It now takes me absolutely less than five minutes to mount the base and make all the connections.

THE PROGRAM: The big moment has arrived! The SoftDrill is mounted and ready to run. Double click on the SoftDrill icon on your desk top to open the profiler's program. Here you are presented with a few options. You tell the program which lock you are dealing with and whether you want the program to make its own setup decisions, or whether you want to adjust the setup yourself. (Automatic setup is easiest of course--but I found adjusting the setup myself can improve opening time). After making these few choices, the stepper motor jumps to life, the dial starts turning, and your lock is on its way to being opened.

The SoftDrill begins by parking the wheels in a series of predetermined locations and checking the contact points. After finding a favorable wheel position it begins to look in earnest at one particular wheel--all the time informing the user of what it's doing. You don't have much control at this point over what's happening, but somehow it's reassuring to have the program inform you of its progress! As each wheel's secrets are uncovered, the user is informed of the top five candidates for that wheel's combination.

Perhaps it's the technician in me, but I found it absolutely fascinating to watch SoftDrill do its thing. The more I watched it the more I admired the folks who developed it. When checking contact points the device--like its human counterparts--oscillates the dial and takes several readings for accuracy. Also, SoftDrill seems to be exceedingly thorough. The dial turns in one number increments only--a step that adds a little time to the process but pays back with a very high "successful openings" rate. Lastly, SoftDrill doesn't give up without a fight. If the correct numbers do not turn up after SoftDrill's initial testing, it executes a well-planned attack that very thoroughly examines the lock until it yields--as most inevitably will. SoftDrill not only gives you the precise combination, but actually opens the lock as well!

MY TEST RESULTS: I have experimented with SoftDrill on over 100 attempted safe openings. This involved about 10 different locks (all S&G 6730s), on a variety of safes (including fairly thick-door fire safes). All of this was done either at my offices, or at a number of recent trade shows. Some of the trial combinations used were of my own making, but most were offered up by other folks.

An early version of the software I played with (several months ago) opened virtually every 6730 that met the following criteria:

1. The lock did not have the third wheel set in the forbidden zone.

2. The lock was "handed" correctly.

3. The lock’s third wheel "read" first, followed by wheels two and one.

The first two conditions are not so bad. Both conditions can be compensated for with a little cunning. The third condition was unacceptable though. Most 6730s do indeed read "wheel 3 first", but the goal is to open the really tricky ones as well! I phoned my concerns to the engineer who was writing the code for SoftDrill. After some discussion it was agreed that the device should be able to open locks regardless of which order the wheels read. I was delighted (but knowing the company--not surprised) to learn that the program had been rewritten to cover all possibilities.

To save time, the new program assumes a "3-2-1" lock, but if the opening fails the "wildcard" program is automatically executed. I thought the early version of the software was cool--but this "wildcard" feature is opening locks that had failed to previously yield.

SUCCESS AND THE TIME FACTOR: Most of my successful test openings were completed in 19 to 24 minutes. Several opened in 15 or 16 minutes. Two or three took about 45 minutes. Several took 60 to 69 minutes. I had several locks fail to open. In all fairness I must add that the failed openings all happened when I was using the early software. One of these failings had the last number set in the forbidden zone. Most all of the others did open--once I learned to manually adjust the setup. Of the no-excuse failures (once I had adjusted the setup and tried again), every single one revealed at least two correct numbers on the correct wheels! I

have yet to experience a failed opening using the new software.

"PROBLEM" LOCKS: All of the locks I worked with were in acceptable mechanical order. If your lock has a sticky or poorly aligned dial you should try the usual remedies (tap dial back into alignment and lubricate) before setting up SoftDrill. Although I didn't experience it myself, I am informed by Howard Dame of Mas-Hamilton that he had two locks with mechanical problems opened under his watch. The first was a lock he was using for demonstration purposes at a trade show. The lock had been opened on different combinations by SoftDrill perhaps 200 times. (Although SoftDrill causes a heck of a lot less wear to the lock than a common autodialer, 200 openings would cause severe strain).

After all these openings in the usual 20 minute time frame, the lock suddenly took 45 and 50 minutes to open--but nevertheless opened. Curious, Howard took the lock apart and discovered that the spine keyway had widened causing "loose spline key" syndrome. Experienced safe technicians know that to open such a lock, they need to add numbers when dialing left and subtract numbers when dialing right. SoftDrill had successfully opened this problem lock!

An even trickier problem was solved by SoftDrill. One lock that had been subjected to numerous SoftDrill openings eventually developed a "stuck fly". This problem can be diagnosed and opened by a good safe technician--but I have heard of numerous cases where the safe was drilled. I am informed that SoftDrill successfully opened this problem lock in about 20 minutes. This opening was repeated to make sure it wasn't a fluke. Again the lock opened in a similar time.

SUMMARY: In my experience, which has been limited to about 100 trials using S&G locks in good working order, my opening times have ranged from just under 15 minutes to nearly 69 minutes. The great majority yielded in 19 to 24 minutes. Six locks failed to open even after I manually adjusted the setup. All of the failed tests were conducted using an early version of the software.

THE BOTTOM LINE: This stunning technology does not come cheap. SoftDrill sells to security professionals for $6,995. However, if you are turning away safe openings or don't feel comfortable leaving your autodialer unattended for a day or more, this could be the ticket. Just two safe openings a month at $300 each pays for SoftDrill in one year.

FUTURE DEVELOPMENTS: Even now, software updates are being developed that will support an ever-growing variety of locks. The word from Mas-Hamilton is "Why should we stop with these two locks?". When I asked the obvious question about whether they would go after manipulation-resistant locks, I didn't get a "yes" or a "no"--just a sly smile.

434 (Popup - US PATENT 3024640)
Page: 1,2,3,4,5
435 (Popup - MOSLER MR-302 and MRK-302)
The MR-302 is the most popular form of this design. The MRK-302 is a key changeable model.

The original lock was constructed of brass and delrin or brass and zamak, and contained three wheels. The critical feature that made the lock manipulation-resistant was the design of the shutter. Its manipulation resistance resulted from the drive wheel mechanical design that caused it to "snap" while passing through the drop-in area. and a spring-loaded detent located on the lock body which rested against the drive wheel.

The drive wheel was of a split design: half would be fixed during rotation by a detent. This portion of the wheel would return to its original position upon reaching a certain position. The split drive wheel was held together by a "C" clip and post configuration. The wheel centers are made of zamak, and all are identical with the exception of the #1 wheel, which contains no drive pin on the bottom side. The outer portion of the wheels are constructed of delrin, and have teeth that mesh with the zamak inner wheel.

The cover of this lock is unique, for it holds the wheel pack as well as the detent that depresses the relocker when the cover is properly seated. The fence screw rests and moves within an interior slot, and the cover can only be removed if the bolt is fully extended. Thus, in order to change the combination, the door must be locked open with the bolt protruding.

The MR-302 series lock has the same mounting footprint as the S&G 6730, however the spindle is a smaller diameter and not interchangeable.

436 (Popup - CHICAGO LOCK COMPANY V. FANBERG)
CHICAGO LOCK CO. v. FANBERG, 676 F.2d 400 (9th Cir. 1982)

CHICAGO LOCK CO., A CORPORATION,

PLAINTIFF-APPELLEE,

v.

MORRIS v. FANBERG AND VICTOR FANBERG, CO-PARTNERS, D/B/A A-ADVANCED LOCKSMITH,

DEFENDANTS-APPELLANTS.

No. 80-5000.

United States Court of Appeals, Ninth Circuit.

Argued and Submitted August 3, 1981.

Decided May 6, 1982.

Rehearing Denied July 14, 1982.

Neil F. Martin, San Diego, Cal., for Chicago Lock.

Bruno J. Verbeck, San Diego, Cal., for defendants-appellants.

H. Chester Horn, Jr., Los Angeles, Cal., for intervenor.

Appeal from the United States District Court for the Southern District of California.

Before ELY and NORRIS, Circuit Judges, and PECKHAM,[fn*] District Judge.

[fn*] The Honorable Robert F. Peckham, Chief Judge, Northern District of California, sitting by designation.

ELY, Circuit Judge:

The Chicago Lock Company ("the Company"), a manufacturer of "tubular" locks, brought suit against Morris and Victor Fanberg, locksmiths and publishers of specialized trade books, to enjoin the unauthorized dissemination of key codes for the Company's "Ace" line of tubular locks. The District Court granted summary judgment in favor of the Fanbergs as to the Company's federal

claims of trademark infringement and unfair competition, but held trial on the common law claim of unfair competition under former Cal.Civ. Code § 3369.[fn1]

The court concluded that the key codes for the Company's tubular locks were improperly acquired trade secrets and enjoined distribution of the Fanbergs' compilation of those codes. For the reasons set forth in this opinion, we reverse the District Court and order that judgment be entered in favor of the Fanbergs.

THE FACTS

Since 1933 the Chicago Lock Company, a manufacturer of various types of locks, has sold a tubular lock, marketed under the registered trademark "Ace," which provides greater security than other lock designs. Tubular Ace locks, millions of which have been sold, are frequently used on vending and bill changing machines and in other maximum security uses, such as burglar alarms. The distinctive feature of Ace locks (and the feature that apparently makes the locks attractive to institutional and large-scale commercial purchasers) is the secrecy and difficulty of reproduction associated with their keys.

The District Court found that the company "has a fixed policy that it will only sell a duplicate key for the registered series `Ace' lock to the owner of record of the lock and on request of a bona fide purchase order, letterhead or some other identifying means of the actual recorded lock owner." Finding of Fact No. 14, Excerpt of Record at 89. In addition, the serial number-key code correlations are maintained by the Company indefinitely and in secrecy, the Company does not sell tubular key "blanks" to locksmiths or others, and keys to Ace locks are stamped." Do Not Duplicate." See Excerpt at 86-91.

If the owner of and Ace lock loses his key, he may obtain a duplicate from the Company. Alternatively, he may have a proficient locksmith "pick" the lock, decipher the tumbler configuration, and grind a duplicate tubular key. The latter procedure is quicker than the former, though more costly. The

locksmith will, to avoid the need to "pick" the lock each time a
key is lost, record the key code (i.e., the tumbler configuration) along with the serial number of the customer's lock. See Excerpt at 92. Enough duplicate keys have been made by locksmiths that substantial key code data have been compiled,
albeit noncommercially and on an ad hoc basis.

Appellant Victor Fanberg, the son of locksmith Morris Fanberg and a locksmith in his own right, has published a number of locksmith manuals for conventional locks. Realizing that no compilation had been made of tubular lock key codes, in 1975 Fanberg advertised in a locksmith journal, Locksmith Ledger, requesting that individual locksmiths transmit to him serial number-key code correlations in their possession in exchange for
a copy of a complete compilation when finished. A number of locksmiths complied, and in late 1976 Fanberg and his father began to sell a two-volume publication of tubular lock codes, including those of Ace locks, entitled "A-Advanced Locksmith's Tubular Lock Codes." In 1976 and 1977 Fanberg advertised in the manuals in the Locksmith Ledger for $49.95 and indicated that it would be supplemented as new correlations became known. See Excerpt at 95-98. About 350 manuals had been sold at the time of
trial. The District Court found that Fanberg "had lost or surrendered control over persons who could purchase the books," id. at 98, meaning that nonlocksmiths could acquire the code manuals.

The books contain correlations which would allow a person equipped with a tubular key grinding machine to make duplicate keys for any listed Ace lock if the serial number of the lock was
known. On some models, the serial numbers appear on the exterior
of the lock face. Thus, Fanberg's manuals would make it considerably easier (and less expensive) for a person to obtain (legitimately or illegitimately) duplicate keys to Ace locks without going through the Company's screening process. This is what caused consternation to the Company and some of its customers. At no time did Fanberg seek, or the Company grant, permission to compile and sell the key codes. Nor did the individual locksmiths seek authorization from the Company or their customers before transmitting their key code data to

Fanberg.

The Company filed a three-count complaint against the Fanbergs, alleging federal question jurisdiction and diversity of citizenship, on December 2, 1976. The complaint, see Excerpt at 1-12, was predicated on theories of trademark infringement under 15 U.S.C. §§ 1051 et seq., federal unfair competition under 15 U.S.C. §§ 1125(a), and California common law unfair competition under former Cal.Civ. Code § 3369. On November 17, 1977, Judge Enright granted summary judgment for the Fanbergs on the federal claims, but left intact the state law claim. See Excerpt at 32-34. The complaint was amended, see Excerpt at 38-46, and a four-day bench trial was held before Judge Kerr on January 23-26, 1979. On November 28, 1979, Judge Kerr entered judgment in favor of the Company and filed findings of fact and conclusions of law. See Excerpt at 75-121.

The court found that the Company's high security policy for its Ace tubular locks, of which the confidential key code data were a part, was a "valuable business or trade secret-type asset" of the Company, and that the Fanbergs' publication of their compilation of these codes so undermined the Company's policy as to constitute "common law unfair competition in the form of an unfair business practice within the meaning of Section 3369 of the Civil Code of the State of California," as broadly interpreted in Barquis v. Merchants Collection Association, 7 Cal.3d 94, 496 P.2d 817, 101 Cal.Rptr. 745 (1972). Excerpt at 118-120. The court enjoined the Fanbergs from publishing or distributing any lists of key code correlations for the Company's registered series Ace tubular locks. See Excerpt at 121.

On this appeal the Fanbergs argue that the District Court erred on three grounds: (1) that the injunction against publication of their book constitutes a prior restraint prohibited by the First Amendment to the United States Constitution; (2) that the

statute
under which the injunction issued, former Cal.Civ. Code § 3369, is
unconstitutionally vague; and (3) that the District Court applied
erroneously the common law doctrine of trade secrets in
concluding that the Fanbergs had committed an "unfair business
practice" under Section 3369.

THE TRADE SECRETS CLAIM

Appellants argue that the District Court erroneously concluded
that they are liable under Section 3369 for acquiring appellee's
trade secret through improper means. We agree, and on this basis
we reverse the District Court.

Although the District Court's Findings of Fact and Conclusions
of Law are lengthy, the thrust of its holding may be fairly
summarized as follows: appellants' acquisition of appellee's
serial number-key code correlations through improper means, and
the subsequent publication thereof, constituted an "unfair
business practice" within the meaning of Section 3369. See
Excerpt at 119-20. Even though the court did not make an explicit
finding that appellee's serial number-key code correlations were
protectable trade secrets, both appellants and appellee premise
their appeal on such an "implicit" finding. See Brief of
Appellee at 13-14. We think it clear that the District Court
based its decision on a theory of improper acquisition of trade
secrets, and in the following discussion we assume arguendo
that appellee's listing of serial number-key code correlations
constituted a trade secret.[fn2]

California courts have adopted the theory of trade secret
protection set out in the Restatement (First) of Torts, § 757,
and the comments thereto, in resolving disputes involving trade
secrets. See Sinclair v. Aquarius Electronics, Inc., 42
Cal.App.3d 216, 116 Cal.Rptr. 654 (1974); Uribe v. Howie, 19
Cal.App.3d 194, 96 Cal.Rptr. 493 (1971); Cal Francisco
Investment Corp. v. Vrionis, 14 Cal.App.3d 318, 92 Cal.Rptr. 201
(1971). Commission of this common law tort is enjoinable under
the purview of "unfair competition" and "unlawful" or "unfair

business practice" under Section 3369. See Barquis v. Merchants Collection Association, 7 Cal.3d 94, 496 P.2d 817, 101 Cal.Rptr. 745 (1972); Hesse v. Grossman, 152 Cal. App.2d 536, 313 P.2d 625, 627 (1957).

The pertinent portion of Section 757 of the Restatement provides:

> One who discloses or uses another's trade secret, without a privilege to do so, is liable to the other if
>
> (a) he discovered the secret by improper means, or
>
> . . . .
>
> (c) he learned the secret from a third person with notice of the facts that it was a secret and that the third person discovered it by improper means . . .
>
> . . . .

Trade secrets are protected, therefore, in a manner akin to private property, but only when they are disclosed or used through improper means. Trade secrets do not enjoy the absolute monopoly protection afforded patented processes, for example, and trade secrets will lose their character as private property when the owner divulges them or when they are discovered through proper means. "It is well recognized that a trade secret does not offer protection against discovery by fair and honest means such as by independent invention, accidental disclosure or by so-called reverse engineering, that is, starting with the known product and working backward to divine the process." Sinclair, 42 Cal.App.3d at 226, 116 Cal.Rptr. at 661.

Thus, it is the employment of improper means to procure the trade secret, rather than mere copying or use, which is the basis of liability. Restatement (First) of Torts, § 757, comment a (1939). The Company concedes, as it must, that had the Fanbergs

bought and examined a number of locks on their own, their reverse
engineering (or deciphering) of the key codes and publication
thereof would not have been use of "improper means." Similarly,
the Fanbergs' claimed use of computer programs in generating a
portion of the key code-serial number correlations here at issue
must also be characterized as proper reverse engineering. Excerpt
at 96, 100-01; Brief of Appellee at 29-30. The trial court found
that appellants obtained the serial number-key code correlations
from a "comparatively small" number of locksmiths, who
themselves had reverse-engineered the locks of their customers.
See Excerpt at 96-97. The narrow legal issue presented here,
therefore, is whether the Fanbergs' procurement of these
individual locksmiths' reverse engineering data is an "improper
means" with respect to appellee Chicago Lock Company.

The concept of "improper means," as embodied in the
Restatement, and as expressed by the Supreme Court, connotes the
existence of a duty to the trade secret owner not to disclose the
secret to others. See Restatement (First) of Torts, § 757,
comment h (1939). "The protection accorded the trade secret
holder [i.e., in this case the Company] is against the
disclosure or unauthorized use of the trade secret by those to
whom the secret has been confided under the express or implied
restriction of disclosure or nonuse." Kewanee Oil Co. v. Bicron
Corp., 416 U.S. 470, 475, 94 S.Ct. 1879, 1883, 40 L.Ed.2d 315
(1974) (emphasis added).

Thus, under Restatement § 757(c), appellants may be held liable
if they intentionally procured the locksmiths to disclose the
trade secrets in breach of the locksmiths' duty to the Company
of nondisclosure. See Restatement (First) of Torts, § 757,
comment h (1939). Critical to the District Court's holding,
therefore, was its conclusion that the individual locksmiths,
from whom the Fanbergs acquired the serial number-key code
correlations, owed an implied duty to the Company not to make the
disclosures. See Excerpt at 116.

We find untenable the basis upon which the District Court

concluded that the individual locksmiths owe a duty of nondisclosure to the Company. The court predicated this implied duty upon a "chain" of duties: first, that the locksmiths are in such a fiduciary relationship with their customers as to give rise to a duty not to disclose their customers' key codes without permission, see Excerpt at 116; and second, that the lock owners are in turn under an "implied obligation [to the Company] to maintain inviolate" the serial number-key code correlations for their own locks, see id.

The court's former conclusion is sound enough: in their fiduciary relationship with lock owners, individual locksmiths are reposed with a confidence and trust by their customers, of which disclosure of the customers' key codes would certainly be a breach. This duty, however, could give rise only to an action by "injured" lock owners against the individual locksmiths, not by the Company against the locksmiths or against the Fanbergs.[fn3]

The court's latter conclusion, that lock owners owe a duty to the Company, is contrary to law and to the Company's own admissions. A lock purchaser's own reverse-engineering of his own lock, and subsequent publication of the serial number-key code correlation, is an example of the independent invention and reverse engineering expressly allowed by trade secret doctrine. See Sinclair, 42 Cal.App.3d at 226, 116 Cal.Rptr. at 661.[fn4] Imposing an obligation of nondisclosure on lock owners here would frustrate the intent of California courts to disallow protection to trade secrets discovered through "fair and honest means." See id. Further, such an implied obligation upon the lock owners in this case would, in effect, convert the Company's trade secret into a state-conferred monopoly akin to the absolute protection that a federal patent affords. Such an extension of California trade secrets law would certainly be preempted by the federal scheme of patent regulation. See Kewanee Oil Co. v. Bicron Corp., 416 U.S. 470, 94 S.Ct. 1879, 40 L.Ed.2d 315 (1974); Compco Corp. v. Day-Brite Lighting, Inc., 376 U.S. 234, 84

S.Ct. 779, 11 L.Ed.2d 669 (1964); Sears, Roebuck & Co. v. Stiffel Co., 376 U.S. 225, 84 S.Ct. 784, 11 L.Ed.2d 661 (1964).

Appellants, therefore, cannot be said to have procured the individual locksmiths to breach a duty of nondisclosure they owed to the Company, for the locksmiths owed no such duty. The Company's serial number-key code correlations are not subject to protection under Restatement § 757, as adopted by the California courts, because the Company has not shown a breach of any confidence reposed by it in the Fanbergs, the locksmiths, or the lock purchasers - i.e., it has failed to show the use of "improper means" by the Fanbergs required by the Restatement.

The District Court's conclusion that the Fanbergs committed an "unfair business practice" under Section 3369, therefore, must be reversed, and judgment should be entered in favor of appellants.
In view of the foregoing we find it unnecessary to reach appellants' First Amendment and vagueness claims.

REVERSED AND REMANDED with instructions that judgment be entered in favor of defendants-appellants.

[fn1] Former Section 3369 was recodified virtually verbatim in 1977 as Cal.Bus. & Prof. Code §§ 17200-17203 (West). For simplicity this opinion will refer to the statute throughout as "Section 3369."

[fn2] Both parties devote much of their argument to whether the Company's key code data properly constitutes a "trade secret" within the meaning of Restatement (First) of Torts § 757, comment b (1939). See Brief of Appellants at 30-33; Brief of Appellees at 13-20. Although for purposes of our holding we may assume arguendo that the correlations do constitute a trade secret, we think it clear that because the correlations are an unpatented compilation of information, they constitute a "trade secret" within the meaning of the Restatement as adopted by California courts. See Sinclair v. Aquarius Electronics, Inc., 42 Cal.App.3d

216, 222, 116 Cal.Rptr. 654, 658 (1974); Restatement (First) of Torts § 757, comment b (1939).

[fn3] The Company premised its complaint on a violation of its own rights under trade secret law; the Company did not allege violations of the lock owners' rights. Cf. Barquis v. Merchants Collection Ass'n, 7 Cal.3d 94, 110, 101 Cal.Rptr. 745, 756 (1972) (Section 3369 permits members of the public to sue on behalf of the public generally); Hernandez v. Atlantic Finance Co. of Los Angeles, 105 Cal.App.3d 65, 72-73, 164 Cal.Rptr. 279, 284 (1980) (statute authorizes suits for injunction by individuals on behalf of the general public).

[fn4] If a group of lock owners, for their own convenience, together published a listing of their own key codes for use by locksmiths, the owners would not have breached any duty owed to the Company. Indeed, the Company concedes that a lock owner's reverse engineering of his own lock is not "improper means." See Brief of Appellee at 24.

437 (Popup - RUBIN V. COORS)
SUPREME COURT OF THE UNITED STATES

Syllabus

RUBIN, SECRETARY OF THE TREASURY v. COORS BREWING CO.

certiorari to the united states court of appeals for the tenth circuit

No. 93-1631. Argued November 30, 1994 -- Decided April 19, 1995

Because §5(e)(2) of the Federal Alcohol Administration Act (FAAA or Act) prohibits beer labels from displaying alcohol content, the federal Bureau of Alcohol, Tobacco and Firearms (BATF) rejected respondent brewer's application for approval of proposed labels that disclosed such content. Respondent filed suit for relief on the ground that the relevant provisions of the Act violated the First Amendment's protection of commercial speech. The Government argued that the labeling ban was necessary to suppress the threat of "strength wars" among brewers, who, without the regulation, would seek to compete in the marketplace

based on the potency of their beer. The District Court invalidated the labeling ban, and the Court of Appeals affirmed. Although the latter court found that the Government's interest in suppressing "strength wars" was "substantial" under the test set out in Central Hudson Gas & Electric Corp. v. Public Serv. Comm'n of N. Y., 447 U.S. 557, the court held that the ban violates the First Amendment because it fails to advance that interest in a direct and material way.

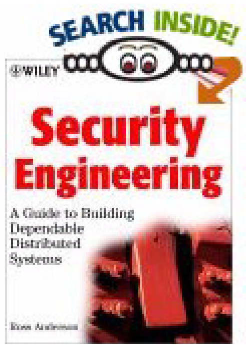
Held: Section 5(e)(2) violates the First Amendment's protection of commercial speech. Pp. 3-15.

(a) In scrutinizing a regulation of commercial speech that concerns lawful activity and is not misleading, a court must consider whether the governmental interest asserted to support the regulation is "substantial." If that is the case, the court must also determine whether the regulation directly advances the asserted interest and is no more extensive than is necessary to serve that interest. Central Hudson, supra, at 566. Here, respondent seeks to disclose only truthful, verifiable, and nonmisleading factual information concerning alcohol content. Pp. 3-6.

(b) The interest in curbing "strength wars" is sufficiently "substantial" to satisfy Central Hudson. The Government has a significant interest in protecting the health, safety, and welfare of its citizens by preventing brewers from competing on the basis of alcohol strength, which could lead to greater alcoholism and its attendant social costs. Cf. Posadas de Puerto Rico Associates v. Tourism Co. of Puerto Rico, 478 U.S. 328, 341. There is no reason to think that strength wars, if they were to occur, would not produce the type of social harm that the Government hopes to prevent. However, the additional asserted interest in "facilitat[ing]" state efforts to regulate alcohol under the Twenty first Amendment is not sufficiently substantial to meet Central Hudson's requirement. Even if the Government possessed the authority to facilitate state powers, the Government has offered nothing to suggest that States are in need of federal assistance in this regard. United States v. Edge Broadcasting Co., ___ U. S. ___, ___, distinguished. Pp. 7-9.

(c) Section 205(e)(2) fails Central Hudson's requirement that the measure directly advance the asserted government interest. The labeling ban cannot be said to advance the governmental interest in suppressing strength wars because other provisions of the FAAA and implementing regulations prevent §205(e)(2) from

furthering that interest in a direct and material fashion. Although beer advertising would seem to constitute a more influential weapon in any strength war than labels, the BATF regulations governing such advertising prohibit statements of alcohol content only in States that affirmatively ban such advertisements. Government regulations also permit the identification of certain beers with high alcohol content as "malt liquors," and they require disclosure of content on the labels of wines and spirits. There is little chance that §205(e)(2) can directly and materially advance its aim, while other provisions of the same Act directly undermine and counteract its effects. Pp. 9-13.



(d) Section 205(e)(2) is more extensive than necessary, since available alternatives to the labeling ban--including directly limiting the alcohol content of beers, prohibiting marketing efforts emphasizing high alcohol strength, and limiting the ban to malt liquors, the segment of the beer market that allegedly is threatened with a strength war--would prove less intrusive to the First Amendment's protections for commercial speech. Pp. 14-15.

2 F. 3d 355, affirmed.

Thomas, J., delivered the opinion of the Court, in which Rehnquist, C. J., and O'Connor, Scalia, Kennedy, Souter, Ginsburg, and Breyer, JJ., joined. Stevens, J., filed an opinion concurring in the judgment.

438 (Popup - SECURITY ENGINEERING)

Security Engineering: A Guide to Building Dependable Distributed Systems, by Ross J. Anderson.

439 (Popup - Alphonse Bertillion Identification of Criminals)

The following description of the Bertillion identification method has been provided as an excerpt from the Central Missouri State University criminal justice system.

Alphonse Bertillion

In 1877, Alphonse Bertillion was appointed to the Prefecture of Police as a records clerk. He shortly became disgusted with the way in which records were maintained. Within a year he presented a new scheme for identifying criminals, based on body and head measurements. Using this technique (anthropometric or "man measurement"), he identified his first recidivist in 1883. In 1884, Bertillion identified 241 and was recognized for developing the first scientific method of identifying a criminal to be used by a police force.

This system was soon incorporated by the British and American police. Although it would be replaced by fingerprinting in the early twentieth century, the Bertillion system was responsible for bringing precision into a haphazard process. Prior to this development, criminal identification depended on the memories of witnesses. Criminals were able to commit their crimes and disappear into the streets with the knowledge that the police were unlikely to capture them. Bertillion made identification possible without requiring the witness to be present at the arrest. More than just a system of measurements, Bertillion also created the portrait parle (speaking likeness) system which was a precise method of describing a person's facial and physical characteristics. This portion of Bertillion's system is still used by the majority of the world's police departments, although it has lost much of its exactness due to the evolution of shortcuts in the process.

The difficulty that finally led to the discrediting of Bertillion's anthropometric system was the inability to ensure uniformity in measurement. The problem was two-fold. First, different officers frequently obtained different measurements from the same individual. This was caused by a lack of agreement on how tightly the calipers should fit in order to obtain the measurement. The second problem was caused by the aging process. As people age, so do many of the bodily characteristics, especially if the original measurements were obtained when the person was not yet an adult.

The system was ultimately discredited as a result of the Will West case in 1903. Will West was mistakenly identified in Leavenworth, Kansas as a previous convict, William West. The use of fingerprints allowed the police to identify the real William West, who was serving time in another prison. This case marked the end of anthropometric measurements and the beginning of fingerprinting as the principle means of criminal identification.

Bertillion received great criticism as a result of this, which sometimes obscures his other achievements. It was those other contributions, however, that make this man one of the great pioneers in criminalistics. He was instrumental in introducing the use of photography to police investigations, especially at crime scenes. He introduced handwriting and forgery analysis, ballistics, galvanoplastic preservation of footprints, the dynamometer, which was employed in determining the degree of force used in housebreaking, and the "Bertillion Kit", the case containing instruments of evidence collection taken by detectives to a crime scene.

440 (Popup - FALSE ACCEPT RATE IN BIOMETRICS)
A false acceptance allows a person to access a system with biometric features that have not been registered on the system.
441 (Popup - FALSE REJECT RATE IN BIOMETRICS)
A false rejection rate prevents the legitimate user from accessing a system for which he or she has access authority.
442 (Popup - DEPARTMENT OF ENERGY)
Video and images from DOE were provided by the Office of Security and Safety Performance Assurance, in German Town, Maryland.

Certain materials were excerpted from the **NRC Inspection Manual** and the **Physical Security Systems Inspections Guide**, because of their application to all intrusion detection system design and evaluation.
443 (Popup - CASING AN ESTABLISHMENT)

This term designates casing or surveillance of a location by a burglar.

444 (Popup - PUNCHING)

This technique is known as "punching." See **Chapter 35**.

445 (Popup - ALFRED C. HOBBS AND THE BRAMAH LOCK)

See the information in **Chapter One** regarding the Bramah lock and the Great Exhibition, and how Alfred C. Hobbs bypassed a mechanism that had never been compromised..

446 (Popup - FIREPROOF WORD DERIVATION)

The term "fireproof" also appears as "fire proof" and "fire-proof" in this text, due to the differing use of English, especially in early works. You may wish to search for all three derivations.

447 (Popup - PROPERTIES OF ALUMINOUS EARTH)

"Aluminous earth is also employed in different combinations by the dyer and the calico printer, as a mordant for fixing various colours; and upon the continent it is artificially combined with sulphuric acid, in order to form alum. But we possess the compound, or alum slate, ready formed in abundance. It is procured on the sea-coast of the northeast part of Yorksire, from Whitley to Stockton, a distance of about fifty miles. The slate, when taken from the bed, is broken to pieces by the aid of fire, and afterwards further acidified by being frequently moistened, and by exposure to the air. When the efforescence has taken place it is put into lixiviating vessels for the extraction of the salt. The saline liquor is then boiled down to the proper strength for crystallization; previous to which is added a portion either of sulphate or muriate of potash. Alum, indeed, cannot be made without ammonia or potash, as it is a triple salt."

Parkes Elements of Chemistry

448 (Popup - DOCUMENT AND RECORD PROTECTOIN FROM FIRE)

This is the earliest development of record and data protection containers from the effects of fire. Not a great deal has changed within the past 150 years.

449 (Popup - POWDER-PROOF AND GUNPOWDER PROOF LOCKS)

You may wish to search for this topic under gunpowder, gunpowder proof, powder proof, and powder-proof, as these terms appear differently in each text.

450 (Popup - PICKING, DECODING, AND SIMULATION OF A KEY)

This discussion complements that which appears in Chapter 29-31 with respect to the simulation of a key to open a lock. Various decoding systems provide the critical information regarding the position of the "security parts"; the John Falle variable key

generation system allows the simulation of the correct key using the decoded information.

451 (Popup - WARDED LOCK DEFINITION)

Definition of a warded lock.

452 (Popup - DOUBLE DETAINER LOCKING THEORY)

This is the definition of the double detainer locking theory described elsewhere in this text.

453 (Popup - LETTER OR PUZZLE LOCK)

This reference also describes the letter or puzzle lock, or permutation lock. It is also used to describe the padlock, letter lock, or finger ring lock.

454 (Popup - FENCE AND GATE RELATIONSHIP)

Note the description applies equally to the modern combination lock.

455 (Popup - PROGRAMMABLE COMBINATION LOCK)

This is likely the first instance of a programmable combination lock, much like the Corbin Sessamee that is so common on luggage today.

456 (Popup - COMBINATION LOCK)

This term refers to a combination lock.

457 (Popup - FALSE NOTCHES AND GATES)

This provides an interesting history of the use of false notches and gates within combination locks to enhance security.

458 (Popup - PROGRAMMABLE COMBINATION LOCK)

This is another description of the programmable combination lock.

459 (Popup - MANIPULATION AND EARLY COMBINATION LOCKS)

This refers to the manipulation of early combination locks.

460 (Popup - PROTECTION AGAINST FORCED ENTRY FOR LOCKS)

This is an equally applicable definition for safes produced today and those of almost two centuries ago, with respect to forced entry techniques and security enhancements to protect against such methods of forced entry.

461 (Popup - DAY LOCKING OF COMBINATION LOCKS)

Perhpas the earliest definition of "day locking" of a combination lock.

462 (Popup - DIFFERS OR PERMUTATIONS WITHIN A COMBINATION LOCK)

The subject of permutations or differs for a combination lock was just a relevant two centuries ago as it is today.

463 (Popup - TENTATIVE METHOD OF LOCK PICKING)

This is a description that encompasses the tentative method of lock picking, described elsewhere in this text.

464 (Popup - MANIPULATION OF COMBINATION LOCKS)

This is a discussion of the manipulation technique as applied to a combination lock almost two centuries ago.

465 (Popup - BIT AND BARREL KEYS)
This is the definition of the bit or barrel key, defined elsewhere in this text.

466 (Popup - DEVELOPMENT OF WARDS)
This description examines the development of the ward to block entrance into the keyway by all but the proper key.

467 (Popup - BULLETS)
This describes the development of bullets or variations in the ward pattern within a keyway.

468 (Popup - IMPRESSION OF WARDED LOCK)
This description shows how easy an impression of the mechanism can be produced from a warded lock.

469 (Popup - FALSE NOTCHES IN WARDED LOCK)
False notches in warded locks were the forerunner to the utilization of this technique in lever locks.

470 (Popup - WARDED LOCKS AND A SECURITY ANALYSIS)
It can be seen that the same problem existed almost two centuries ago in the analysis of locks for their security and resistance to bypass. In many ways, little has changed between then and now.

471 (Popup - LOCKS AS WORKS OF ART)
It will be recalled from the discussion in Chapter 1 of **Locks, Safes, and Security** that warded locks were considered to be works of art, and defined wealth and prestige of the owner by their design.

472 (Popup - DIFFERS IN THE WARDED LOCK)
The warded lock is inherently insecure because of the limited number of differs that are available.

473 (Popup - APPEARANCE OF THE WARDED KEY PROVIDED A FALSE SENSE OF SECURITY)
The intricate design of the warded key provided a false sense of security to its owner, believing that the complexity meant that the internal mechanism was equally secure. Unfortunately, this was not the case.

474 (Popup - PICKING AND IMPRESSIONING WARDED LOCKS)
A description of how to pick or impression a warded lock illustrates the development of the technique for later, more secure mechanisms.

475 (Popup - FALSE KEYHOLES IN THE WARDED LOCK)
One of the measures of security in the warded lock was the false keyhole. Another was the design an extremely intricate keyway.

476 (Popup - H GATING WITHIN A LEVER)
Note the increasd security provided by the H gating.

477 (Popup - PICKING LEVER LOCKS)
This is an excellent description of the difficulty in picking a

lever lock.

478 (Popup - DIFFERS)

This description refers to the inherent problem with warded locks in particular; their being very few differs available, regardless of the design of the keyway and key.

479 (Popup - CALCULATION OF DIFFERS)

The calculation of differs for a lever lock.

480 (Popup - IMPRESSIONING OF WARDED LOCKS)

This is an excellent analysis regarding the capability to impression warded locks, and the procedures that were employed almost two hundred years ago.

481 (Popup - SECURITY OF THE BARRON LOCK)

This is an interesting and relevant discussion of the security defects that are inherent in the Barron lock.

482 (Popup - TENTATIVE METHOD OF PICKING)

This is a description and reference to the tentative method of picking of lever locks, still in use today.

483 (Popup - FALSE NOTCHES IN THE BRAMAH LOCK)

This is a description of the employment of false notches within the Bramah lock. They were utilized to frustrate the tentative method of picking. Not much has changed in the the modern lock design. The reader may also be interested in the video segment with Jeremy Bramah that describes the development of the Bramah lock by his ancestor.

484 (Popup - KNOCK-OFF LOCKS)

This is an early instance of the problem of knockoff locks and their lack of security. It is easy to see how the public would be confused and deceived into believing that they were purchasing an original Bramah high security mechanism.

485 (Popup - BRAMAH AS A PROLIFIC INVENTOR)

Joseph Bramah was a prolific inventor, having secured over twenty patents for wide ranging inventions.

486 (Popup - INVENTOR OF FALSE NOTCHES AND GATES)

This individual may well be the inventor of the security enhancement known as false notches and gates. That simple premise, now taking many forms on both levers and pin tumblers as notches, gates, and security tumblers, has significantly contributed to the security of all locks.

487 (Popup - CHANGEABLE OR PROGRAMMABLE LOCK)

This may be one of the first instances of a changeable key or programmable lock.

488 (Popup - NIGHTLATCH AND LOIDS)

This section describes a nightlatch, and how such a mechanism can be opened with a loid or flexible card.

489 (Popup - DOUBLE LOCKS PROVIDE ADDED SCURITY)

As described in Chapter 31, John Falle has developed a system to bypass the mechanism developed by CISA which is a double lock similar to that described in this section. The CISA mechanism provides for a pin tumbler lock to be inserted so as to block entry of the lever lock until the secondary lock is removed.

490 (Popup - MOFIDIED PIPE KEY)

This is an interesting modification to the design of the traditional pipe key for the warded lock. There are no wards on the key or within the lock because of its design.

491 (Popup - MULTI-POINT LOCKING DOOR ASSEMBLY)

This is one of the first instances of a multipoint locking system.

492 (Popup - CHUBB DETECTOR LOCK)

This appears to be the first instance of the Chubb Detector within a patent issued to Chubb. It was a revolutionary concept.

493 (Popup - CALCULATION OF DIFFERS IN THE LEVER LOCK)

This is an excellent description of the calculation of the number of differs, change keys, or key combinations within a lever lock.

494 (Popup - BARREL AND CURTAIN)

This is an excellent description of the barrel and curtain design.

495 (Popup - KNOCK-OFF LOCKS)

It would appear that the problem of knockoff locks is as old as the craft itself.

496 (Popup - RUTHERFORD TIME LOCK)

This is the original patent for the time lock, invented by William Rutherford jr. of Scotland. Information regarding this mechanism is found elsewhere in the text.

497 (Popup - PROGRAMMABLE LEVER LOCK)

This is another example of a programmable or changeable lever lock. Some of the modern locks utilize this same principle.

498 (Popup - PROGRAMMABLE LOCK AND KEY)

This is another example of a programmable lock and key.

499 (Popup - BASIS OF THE SIDEBAR DESIGN)

This appears to be the early beginnings of the sidebar design, as employed by Abloy in their disklock.

500 (Popup - note)

This ingenious workman, who is e self-taught musician, a repairer and tuner of orgams, pianofortes, musical bores, clocks, watches, etc., is the inventor of percussion-cap, a circular percussion-cap box, which is a beautiful contrivance for carrying two or three dozen caps in a circular disc, so that a cap is always ready to fix on the nipple of the gun. By forcing the side of the box against the nipple it fixes a cap upon the latter; when withdrawn, the mechanism of the box brings forward another

cap ready for immediate use, and so on till the whole are expended. As it is difficult to handle a percussion cap with cold fingers, besides the risk of losing it, this novel contrivance must prove useful; and had its inventor made it known earlier (instead of keeping it to himself since 1827), it might have been of considerable value to our army in the late war.

501 (Popup - note)

The slide forming part of this lock makes an excellent sash fastener piece of iron, inserting it in the knob, then securing the knob on to the spindle close to the door, and fastening it in such position by a small setscrew in the neck of the knob. Previous to this invention a carpenter could not fit a spindle to a door, unless the spindle happened to be of the exacyt size to suit the particular thickness of the door; but this simple invention permits the carpenter to fit all doors alike with these spindles, whether of one or twelve-inch or any intermediate thickness.

502 (Popup - note)

[1] "But is there not his danger, that at the same time we shall be giving lessons to thieves? It is not very probable that they will seek instruction of us, or that they have any need of it; they are greater masters in the art of opening doors than we can pretend to be. Let us then learn the art of opening locked doors, in order that we may acquire that of securing them in such a way as to leave little or nothing to be feared on account of their security."

503 (Popup - Popup)

[2] It may be stated as a remarkable fact that a locksmith has seldom been convicted of a burglary.

504 (Popup - Popup)

[3] See our remarks on this subject in the chapter on keys.

505 (Popup - TUMBLER LOCKS)

The use of the term "tumbler lock" and lever tumbler lock is the same.

506 (Popup - IMPRESSIONING OF LEVER LOCKS)

This is an interesting method to impression lever locks, and is quite different than the use of plasticine, discussed elsewhere in this text.

507 (Popup - ON THE CONSTRUCTOIN OF LOCKS)

[4] Tomlinson's Rudimentary Treatise on the Construction of Locks.

508 (Popup - TENTATIVE METHOD OF PICKING)

This is an excellent summary of the theory underlying the tentative method of picking.

509 (Popup - TENTATIVE METHOD OF PICKING: BACKGROUND INFORMATION)

[5] We believe the method of picking locks with movable obstructions to the passage of the bolt by the tentative process was first made publicly known in this country at a special general meeting of the Society of Arts on the 30th of June, 1851, when a paper was read by Mr. Paul R. Hodge "On the progress of improvements in locks in the United States of

America."

510 (Popup - TOW-IN-ONE PICK FOR LEVER LOCKS)

This is the precise design of modern two-in-one picks that are utilized to manipulate lever locks.

511 (Popup - ALFRED HOBBS ON THE TENTATIVE METHOD OF PICKING LEVER LOCKS)

This is another excellent description of the tentative method of picking a lever tumbler lock, provided by Alfred C. Hobbs.

512 (Popup - Popup)

[6] The picking of these locks led Mr. Chubb to construct his locks with a serrated stump and false notches in the levers, as will be described in the next chapter.

513 (Popup - ALFRED C. HOBBS PICKS THE BRAMAH LOCK)

The reader may wish to view the video inerview between the author and Jeremy Bramah that was conducted in London in 2001, wherein the challenge to Bramah and the bypass of the Bramah lock was discussed.

514 (Popup - ALFRED C. HOBBS OPENS THE BRAMAH LOCK)

This is an excellent description of the events that surrounded the famous Bramah challenge and subsequent opening of the lock that had defied picking for almost fifty years. The storefront of 124 Piccadilly is replicated in the British Science Museum in London, and sets the backdrop for the introduction of the Alfred Hobbs book that is contained within this Infobase.

515 (Popup - DESCRIPTION OF THE BRAMAH LOCK)

This is a description of the original Bramah lock that was opened by Hobbs, and was seen in the interview between the author and Jeremy Bramah.

516 (Popup - COMMENT BY ALFRED C. HOBBS)

[7] "Much larger than any lock Messrs. Bramah make for sale."

Mr. Hobbs

517 (Popup - Popup)

[8] The late Mr. Maudslay is intended to be here alluded to.

518 (Popup - DESCRIPTION OF THE SPRINGS IN THE BRAMAH LOCK)

[9] The springs do not, as has been stated, afford a pressure of thirty or forty pounds, but only thirteen pounds." Bramah and Co.

519 (Popup - Popup)

[10] "A thing quite impossible to be done in the lock." Mr. Hobbs

520 (Popup - Popup)

[11] The same lock is now being fitted up with the improvements which Bramah and Co. have adopted for some years past, and some trifling change suggested by the recent trial." Messrs. Bramah

521 (Popup - Popup)

12 This does not accord with the previous statement "that portions of the sliders presented the appearance of having been bent and straightened again."

522 (Popup - HOBBS OPENS THE BRAMAH LOCK: THE RESULT)

To this day, nobody knows precisely how Hobbs was able to open the Bramah lock. See the video interview between the author and Jeremy Bramah, a descendent of Joseph Bramah.

523 (Popup - Popup)

13 Mr. Smith was in the room several times, and on my second visit to the lock he introduced Lord---; and on my third visit I Allowed Mr. Smith and the foreman of Messrs. Bramah's lock manufactory to examine the lock." Mr. Hobbs

524 (Popup - Popup)

14 This was in strict accordance with the agreement.

525 (Popup - Popup)

15 "This was exactly what I did." Mr. Hobbs

526 (Popup - Popup)

16 "The price of the lock to which Mr. Hobbs' certificates, contained in his pamphlet, refer, appears as before stated to be upwards of 50 pounds."

527 (Popup - COMMENT BY ALFRED HOBBS)

17 "Compare this letter and objections with the terms and conditions agreed upon before commencing the trial." Mr. Hobbs

528 (Popup - COMMENTS BY BRAMAH)

18 Mr. Hobbs stated he preferred no one being present, as it made him nervous. If the operation was so delicate, what chance would a burglar have?" Messrs. Bramah.

529 (Popup - COMMENT BY BRAMAH)

19 "This means as far as he could through the keyhole." Messrs. Bramah

530 (Popup - COMMENTS BY BRAMAH REGARDING THE CONTEST)

20 "The lock remained in the window for four months expressly for Mr. Hobbs to make a second trial. He did not make the attempt; it was then only removed to stop the idle applications of men and boys which took up one person's time to attend to." Messrs. Bramah

531 (Popup - COMMENT BY ALFRED HOBBS REGARDING THE BRAMAH LOCK)

21 "The lock was the same in every particular as the locks made and sold by Messrs. Bramah at the present day." Mr. Hobbs

532 (Popup - COMMENT BY ALFRED HOBBS)

22 "The lock was fitted with a trap so that anything but its true key or the true key with the least dust in it would so disarrange the lock that it could not be opened by any means applied through the key-hole." Mr. Hobbs

533 (Popup - DESCRIPTION OF THE TECHNIQUE USED BY HOBBS TO OPEN THE BRAMAH LOCK)

This is a hypothetical description of how Hobbs was able to open the Bramah lock.

534 (Popup - SEPARATE KEY BIT FROM SHANK OR STEM FOR SAFE LOCKS)

This is now a common practice for high security lever locks

utilized on safes. The bit of the key simply unscrews from the shank, and is convenient to carry.

535 (Popup - NOTES ON THE HOBBS LOCK)

For the figures here referred to see the sheets Nos. 1 and 2 annexed to the complete specification, at the Patent Office, London.

536 (Popup - RINGING THE COMBINATION OF A LOCK)

This term is often used in this text. It refers to the practice of generating a key for every differ or permutation until the proper bitting pattern is discovered.

537 (Popup - Popup)

[1]The real writers of these anonymous letters are known to many, as they are to ourselves.

538 (Popup - FOOTNOTE 8)

In a six-lever lock, constructed with one of the levers "dead" (that is, the dead lever always remains in the same position, and does not require to be lifted in locking and unlocking), will tease even an expert and practiced lock-picker more than all the other five added together.

539 (Popup - MANIPULATION OF COMBINATION LOCKS)

The reader should view the materials in **Chapter 36**, including the excellent discussion of manipulation by Mark Bates.
